Apple Harvey's Wiltshire Defiance (*W. E.*).—This very fine culinary Apple is described in the "Fruit Manual" as handsomely shaped, but having five angles descending from the apex till they are lost in the base. These angles are more acute in some fruits than others. In yours they are somewhat obscure. When the fruit is ripe it is described as a deep sulphur yellow covered all over with minute russety dots, with here and there ramifying patches of russet. Eye pretty large and open, with short ragged segments, set in a rather angular shallow basin. Stalk short, not extending beyond the base, and inserted in a round deep cavity, lined with rough scaly russet. The core is also described as very small for the size of the fruit, stamens median, and tube conical. You will perceive how closely your fruit agrees with those characteristics. We suspect there is another Wiltshire Defiance, the tree being less productive than Harvey's, and the fruits, though large, less handsome. We have occasionally seen very fine dishes of Harvey's Wiltshire Defiance exhibited by Messrs. Veitch & Sons. We have also observed trees in some Kentish fruit gardens pictures of beauty when laden with symmetrical, handsome fruits.

Large Peach (*J. F. Simpson*). — The variety, of which you send samples, is not the Alexandra Noblesse, the flesh of which is pale at the stone, while that of Barrington is tinged with red. The difference between the two fruits in colour shows the influence of light and shade as affecting the appearance of Peaches. The "small" fruit, weighing nearly half a pound, is well coloured; the other, weighing 14 ozs., being almost colourless. A tree, planted five years, and perfecting ninety such fruits, has done its duty well, as you have yours in the cultural attention accorded. It is a difficult matter to name Peaches from the fruits alone, leaves and flowers being important factors to consider. We incline rather strongly to the opinion that your Peach is Sea Eagle, which is one of the finest late varieties in cultivation. The fruits are very large, and colour well by exposure, but are otherwise pale, but rarely destitute of colour. Dr. Hogg, in the "Fruit Manual," as you may see if you have access to that valuable work, describes the flesh of Sea Eagle as deeply stained with red next the stone, the colour extending nearly through the fruit. This is so in the specimens you have sent, and it is this feature mainly (in combination with others) that suggests to us the name of the variety.

Lime for Vine Border (*Vitis Vinifera*).—A fair dressing of fresh lime to use per square yard on a Vine border which has been well fed for some years is 2¼ lbs. It must be the best chalk lime, freshly burned, and slaked with the smallest amount of water necessary to cause it to fall to a fine powder. We, however, prefer air-slaked, as it is less caustic, and less liable to form chloride of lime where chlorine exists largely in the soil. It is best applied in the autumn, or when the Grapes are cut, and if used freshly slaked allow to lie on the surface some time before pointing into the soil; indeed, you may leave it till pruning time, or a short time before the Vines start into growth. We find the most benefit from using about equal parts of air-slaked lime and soot by measure, and applying 1 lb. per square yard immediately after mixing in each year at the time of pruning, and at once pointing in lightly, or using 1 lb. of air-slaked lime alone every other or third year. This is better than heavy dressings, except for special purposes, at distant intervals.

Apples, Pears and Plums at High Elevation (*T. B. C.*).—We suppose you mean growing the fruits named exclusively in the open air without the protection of or against walls, which, of course, implies the setting aside of the varieties that require such aid to arrive at perfection, and confining the culture to the ordinary plantation or hardier sorts. These do well at high elevations, selection being made of the most approved for general purposes, and affording the needful shelter from exposed points by breaks of the very hardy kinds or even of forest trees. The fruits grown in such elevated places are generally of high colour and the crops regular, as the situation insures late blossoming and more immunity from the effects of fogs and late spring frosts. You cannot, however, expect fruit at such elevation (700 feet) to be equal to that grown at a lower one, but with shelter, if any be needed, for that depends on aspect and local circumstances, good fruit may be grown, especially as the soil is suitable.

Cause of Fungi on Tomato Leaves (*Anxious*). — We do not know what is the precise cause of fungi attacking your Tomato leaves, but that it attacks some plants more successfully than others is certain. You say "the ventilators have been open both night and day in favourable weather," and that the house is a cool one. It would be hot enough a few weeks ago. We do not know whether the plants were attacked then or only since the weather changed. We do not think the added loam and manure brought it into operation. We can tell what the attacking fungus is—namely, Cladosporium fulvum. If you had dusted the plants early and occasionally with any of the advertised fungicides in powder containing 10 per cent. of sulphate of copper, such as antiblight or fostite, you would not have had such a bad case. The powder is best applied with a bellows apparatus, just coating the leaves with the finest possible film, and on every part, under as well as upper side. Repeat at intervals of about ten days, and as necessary afterwards, then the parasite will disappear, and the Tomato plants flourish, not otherwise. They are in a sorry plight, and the worst infested leaves should be promptly removed and burnt.

Burning Clay (*W. W.*).—The best way to burn clay for garden purposes is to form a stack of firewood 5 feet in diameter at the base, and tapering upward to a point at a height of 5 feet, beginning with a few dry faggots in the centre. All round this lay a coating of the clay in lumps to a depth of 1 foot, then set fire to the wood in the centre, and long ere the wood is consumed the clay will be burned through, when add another layer of clay all round, and this will soon be burned through also. The fire is then broken down with a strong iron-handled hoe for the purpose of adding more wood and enlarging the base of operations, placing the largest wood on the hot clay, and finishing off the layer with the smallest to prevent the clay lying too close, and on that a layer of clay all over and around. When the clay is burned through add another layer without any wood, and this being burned another can be added, after which it may be necessary to rake down the heap, add more wood as before, and cover with clay, two or three layers being used before it will be necessary to add more wood, as the fire will have great heat. Thus you may burn the clay, securing a very valuable material on account of the wood ashes and the altered character of the clay, which will fall into small parts or can be easily broken up. The substance suits nearly all kinds of fruit and vegetable crops, being mixed with the ordinary soil in the proportion of about one-third.

Names of Fruits. — *Notice.* — We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. *In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing.* The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. *They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state.* (*E. K.*).—London Pippin. (*W. E.*).—Harvey's Wiltshire Defiance (see above). (*G.*).—1, Peasgood's Nonesuch; 2, Warner's King; 3, Potts' Seedling. The Pear is Beurré Hardy.

THE JOY IN HARVEST.

Man's first ideas, his first wants, are material; indeed, a good many of us never really rise far above the material. It is so hard to find meat and drink, clothes and shelter, that in the pursuit of these necessaries all our energies are absorbed. Every year the struggle gets harder; or is it that our wants get more? We are not contented with what satisfied our pre-elders; we look for luxury where they only expected comfort, and very plain comfort at that.

Still there are yet certain things that we require, and that they required—standard articles of diet which have known no change since time and man began. Man certainly does not live by bread alone, but without it he would be a poor creature. Englishmen are found in all climes, from the Arctic Ocean to the torrid zones of Africa, and though he will accommodate himself to the most primitive forms of living, yet he always has an innate craving for a glass of Bass or Allsopp, a crust of home-baked and a slice off the joint, beef preferred. Flour of the Wheat enters so largely into all our living—perhaps because it is easy of manipulation, perhaps because it is bulky and fills up the corners and chinks. At any rate, we insist on its constant presence on our tables, and there is a great outcry if ever in a remote district we are relegated to oatcake or rye bread as a substitute.

Years ago as a nation we were dependent on ourselves, we were more self-supplying; if through any cause our harvest was deficient in quality or quantity we had to make the best of it, and do as well as we could. The corn crop was the principal crop; its well-being of the most vivid importance alike to the rich man in his palace and the poor man in his cot. A bad English harvest meant a year of indifferent food and of great deprivation. It is only a few of us grey beards who can remember the dark, damp, sticky compound that, after a wet harvest, went by the name of bread. How numberless were the recipes for making a sound loaf out of unsound flour. A skilful housewife with the addition of ricemeal, a little milk, and potato could turn out something fairly eatable; the less said about the loaf of the novice the better. Fancy what this bread was for the invalid or young child; the strong and healthy might make a shift, but to the weaklings it meant a sore privation.

There was a custom in our parish years ago of holding an early, very early, service in the church the first day of harvest to ask for a blessing on the ingathering of the crop, and to offer petitions for favourable weather. How could harvest begin under better auspices? It was a following out of the old Jewish feast of "first fruits." In the Wheat-growing districts you see field after field of golden grain level as a plain, and a man must be very callous whose heart is not uplifted by such a sight in thanksgiving.

What preparation there is before harvest fairly begins! Many weeks before the master and foreman hold anxious consultations as to the number of outside hands that will be required, and the various men are passed in strict review. As one diseased member will affect a whole community, so one careless, or idle, or bad tempered man will upset the equanimity of the whole gang of workers. "No, Tim, you'll not do for me this harvest; you'll never be suited with the beer I find, and we don't want a quarrel in the throng of work." And a slow man sets the pace, and hinders and vexes the quicker workers.

All reapers are carefully inspected, duplicate parts are provided, the horses who have had a season of rest since Turnip time are in the best of "fettle;" the children are set free from the bondage of school, and those who are too young to be bandmakers are still old enough to take out dinners and "'ilowance" or "drinkings." Time was when no harvest was complete without some sons of Erin. Punctually as harvest drew on they appeared in their wonted haunts. A bed of straw in the barn, milk and food from the farmhouse kitchen gave them some insight into English living. The best Irish only came, and if they could desist from fighting and an overplus of beer, made the most excellent of workers. Usually a little "opening out" is done before actual harvest begins, then all hands to the work—master and a lad shepherd. The pony of the missus goes ungroomed, and she takes upon herself all the necessary watering and odd jobs of the garden. The days are all too short for the work there is to do, for in this changeable clime we know not from day to day how the weather may be, and it behoves us to make the best of the sunny hours.

It is not all toil even in the harvest field; there are the pleasant meals behind the stooks, when the children, or possibly the wife and baby, participate with the father in the good things contained in the dinner-basket.

An effort is always made to get "father" some tasty nourishing food, for this month at least. Possibly our south country labourers would be surprised if they saw how excellent is the food all the year round found on the tables of the northern farm labourers. Wages are perhaps better, and certainly food is cheap. It is a pleasant sight to see the father, sat under a stook with his little ones intent on helping him out with the liberal allowance of food mother has sent.

What a comfort it is to see loading fairly begun, and with what energy all work! Never mind daylight going, if there is a good harvest moon it makes a substitute for the sun. A wise foreman will see that the last waggons that have come in in the dark are carefully covered over, to be ready for an early morning start. If a master's eye is necessary in the reaping field, it is ten times more necessary when leading begins. Corn in the same field varies so much, and it is sorry look-out at threshing day if all good, bad, and indifferent have been stacked together. Nothing is much more difficult to deal with than Barley which is full of rank green Clover. The Barley is fit long before the Clover loses its nature, and unless the weather be very fine such corn is a great trial of patience.

"Festina lente—hasten slowly," is a proverb that may well be borne in mind. Nothing is so provoking as heated stacks, and nothing may be more easily avoided. Corn crops are often very deceptive. It is not always that the greatest weight of straw proves the fullest of grain. A fair guess may be arrived at as to yield by the way a sheaf "dips" when lifted up by a fork. We do not like to see it reach the waggon nearly level, and we like, too, to see a fair sprinkling of grain on the waggon body.

What a time for the poultry in the stackyard! what feasting they have by the stack sides! It is an old axiom that no ducks are really good till they have tasted new corn; certainly they manage to put flesh on then. The fields are bare save for bands of busy gleaners, who sweeten their toil with the luscious bramble. The sheep follow apace to pick up stray ears and weeds and hedge-side grass, the plough has turned its even furrow, and the land is again ready for the sower's hand.

WORK ON THE HOME FARM.

Harvest in full swing, and we are longing for rain; of such are the vicissitudes of the farmer's life made up! We have had a few slight showers, but nothing to do material good. Turnips and Potatoes preserve their green appearance; but unless we have copious rainfall before the end of the month these crops must, comparatively speaking, be a failure.

Harvest is progressing well; the later crops have ripened quickly, and have had to wait for the reaper. Fortunately, there has been little wind until to-day, and nearly all is cut down. The gale has shaken out a few grains in a backward piece of Wheat, but nothing worth speaking of. Stooks have been blown in all directions, and men have found tying a work of great difficulty, as also have the difficulties of stacking been great. We should have been very thankful for the wind after a heavy rain, but just now the corn is dry enough, and such a gale as this could well be dispensed with. What a blessing such an one would have been last September.

Wheats are bulking up rather light, and Barley is decidedly the straw crop of the year. As to yield of grain, however, we expect the threshing machine to give the verdict to the Wheat. Barley straw, like that of Wheat, is very yellow and bright, and will make good fodder if well saved. There is very little Clover in the sheaves this year. This is in favour of good harvesting, but against the straw as food.

The young seeds have stood the drought better than we expected, and are not only a full plant, but look fairly lively under difficulties. This is a very satisfactory feature of this dry season, for from such a year we often have a legacy of deficiency in the young seeds which is not fully realised until the full course of four years has been run.

Streams are dried up, but springs stand well, and there is no scarcity of water. Should no rain fall at present there is little prospect of the land working after harvest; the hands not employed in thatching could then be well employed in cleansing water courses not usually dry in ordinary seasons.

REMARKS.

15th.—Bright early; cloudy morning; frequent rain after 1.30 P.M.
16th.—Breezy and pleasant, but cloudy at times.
17th.—Overcast morning, with frequent drizzle; sunny at times in afternoon.
18th.—Frequently sunny, but spots of rain now and again, till 3 P.M., then generally rainy, and heavy rain, with thunder at 4.30 P.M.
19th.—Steady rain from 4 A.M. to 6 A.M.; generally sunny after 7 A.M., but a slight shower at 3 P.M; bright night.
20th.—Overcast, with occasional slight showers, and rain from 9.15 A.M. to 10.15 A.M.
21st.—Sunshine and showers in morning; bright afternoon; high wind throughout.
An unsettled week, with temperature very near the average.—G. J. SYMONS.

NOTES ON CURRANTS.

THE usefulness of Red and Black Currants amongst small fruits in gardens cannot be over-estimated ; they are also of considerable importance to the market grower, as they are in general demand for preserving purposes. Under suitable culture both kinds yield a good return for the space they occupy and the labour required, as they do not impose any severe demands upon either. They can be purchased cheaply at the nurseries, or they can be easily propagated if that system is desired. It is a question of time and convenience which course should be taken for obtaining a stock to commence with. For gardens it is unquestionably more suitable generally to buy the plants properly prepared at a nursery, and it is surprising what excellent little three-year-old bushes are supplied at 3s. or 4s. per dozen when a moderate quantity is required. For large numbers £1 per 100 will procure as good plants as can be desired ; therefore it is not worth while to go to the trouble of increasing stock in gardens where space is restricted and labour is not too abundant. If any scarce or valued sort is to be increased that is another matter, and a small bed will suffice to hold all that are likely to be needed.

Here I should like to say that, though the usual time for making and inserting Currant cuttings is the end of September or early in October, yet I have found the present time more suitable, and in this the practice of an experienced market gardening friend has been followed. For some years he has taken both Red and Black Currant cuttings as soon as the growth was sufficiently firm in August, or even at the end of July, with the leaves still on the shoots, the only requisite being a rather shaded and cool place for the cutting bed. They are taken in the usual way, a foot to 15 inches long, preferably the latter, and about one-third of their length is inserted in the soil, which should be carefully prepared, and the cuttings being pressed into little trenches cut with a spade, so that the base of each cutting is firm on the soil. It should be observed also that all lower buds are taken out, so that a clear stem of at least 3 inches above ground is provided. With a moderate amount of attention in watering if the weather be very hot

and dry, cuttings inserted in this way and at the present time root more quickly and make better plants the following season than those dealt with in the ordinary way later in the year. At least such is my experience of cuttings side by side of the same varieties, and it only confirms that of my friend, who now relies upon this plan entirely.

Where a plantation of Currants is to be formed the ground should be prepared at once, for early planting is as desirable with these as with Gooseberries. They should in fact be planted as soon after the leaves have fallen as may be convenient, and though in favourable seasons the operation may be postponed as late as January, yet it is dangerous, and I have seen some distressing results from late planting. In any case the early planted bushes have a considerable advantage the following season, both in growth and fruit. It is too much the custom to be careless of the soil in which Currants are to grow. They require a fertile and well-prepared site to give the best results. If there is any choice the lighter land should be assigned to the Red Currants. Perhaps no better preparation can be given than a dressing of farmyard or stable manure at the rate of 20 tons to the acre, but fresh, rank manure should never be employed if planting is to follow immediately. Currants do not need strong, raw stimulants, which only excite an excessively vigorous growth that is seldom properly matured, and does not increase the yield of fruit in proportion. If the manure has been stacked in a convenient place, turned occasionally, and the liquid dressings poured over it for a month or two, it becomes fine material for digging into soil that is rather light or poor. In my neighbourhood the finest Red and Black Currants are grown by two or three cottagers, who depend entirely upon earth-closet manure, with which soil has been mixed very freely, together with house drainings applied during the winter occasionally. The bushes are in excellent health, vigorous without being gross, though some of them are old specimens, and they bear surprising crops of fruit, the bushes and berries being usually large.

An annual supply of manurial aid in some form is important in maintaining the health and fruitfulness of Currants, and the most convenient as well as beneficial and cheap dressing I have found is superphosphate of lime, used at the rate of 1 oz. per square yard, or 300 lbs. per acre, applied in the late autumn. I have tried nitrate of soda on several occasions as an additional dressing, but except when it has been necessary to force all the growth possible owing to bad attacks of caterpillar I have not found the effects so marked as might be expected. As with other plants, the foliage certainly assumes a much darker and more healthy-looking colour, but I have not observed any further advantage from the use of nitrate. A good annual surface dressing of old manure either from a stable or farmyard produces far more notable results in the size and quantity of fruit.

The distance at which Currants should be planted will depend to some extent upon the character of the plantation; but there is an unfortunate tendency to plant them too closely, so that at the end of three or four years they are either so crowded that they injure each other, or some have to be sacrificed to make room for the others. It is possible to transplant bushes five or six years old successfully, and this is the best way when ground is available, though it often means the partial loss of a crop at a time when the bushes are most productive, and sometimes before they have really had a chance to repay their cost and the labour involved in planting. Red Currants can be planted at 3 feet apart, but Black Currants should not be less than 4 feet, and the others also are much more satisfactory at the same distance as the minimum, though if Strawberries are to be grown between them in a mixed plantation then 6 feet between the rows should be the minimum.

In connection with this, a word or two may be given respecting planting, for carelessness is more frequently manifest in the treatment of Currants and Gooseberries than with other fruits. As received from the nurseries the roots are commonly bunched and tied together closely, and quite as commonly the bushes are planted without any attempt at spreading the roots out, though I am convinced by experience that such want of care results in the loss of a season, as the roots are deprived of a large portion of their recuperative power when bundled together in a hastily dug hole, as is customary. When a large number have to be planted the cost of labour is a heavy item, and it becomes needful to hasten the work as far as practicable; but it is possible to realise the truth of the saying, "The more haste the less speed," and it is preferable to plant a few hundreds less in a day and insure those which are planted being placed in position properly than to hurry through and find evil results afterwards. It might appear to some that I am attaching too much importance to a simple operation and an ordinary crop, but the simple things are the very ones which are overlooked, and Currants are very much more than an ordinary crop with me; they are equally important to others, and might be so to many more.

Journal readers were at one time favoured by articles from the pen of an able writer whom some of us fancied was one of the honoured leaders of practical horticulture in the present time, and the signature he adopted was "Experientia Docet," which someone very freely rendered as "Experience does it." What a world of meaning there is in that word Experience! How much it teaches, and how fast all fantastic theories disappear under its influence! "Practice with science" is the excellent motto of the Royal Agricultural Society; but I think "Experience with observation" is almost as good.

Regarding varieties of Currants a chapter might be written, and if this could be made the means of throwing a little light upon the confusion which exists in the nomenclature of these fruits it would be useful indeed. Unfortunately this is a serious task, for at the outset we are confronted by the difficulty of determining which are the true types of the respective varieties. For instance, in the trial of Red Currants at Chiswick some five or six years ago Raby Castle is given as a synonym of the Mallow-leaved, yet in the last edition of Dr. Hogg's "Fruit Manual" they are described as distinct varieties, one character alone—that of the foliage—sufficing to distinguish them, the Mallow-leaved having large pale soft leaves, while Raby Castle has its leaves "dark bluish green, very rugose, and darker than those of any other variety." Again, Red Cherry is given in the Chiswick Report as distinct from La Versaillaise, whereas Dr. Hogg cites the latter as a synonym of the former. A third instance is afforded by Fay's Prolific, which, in the R.H.S. Report, appears as a synonym of Red Cherry, yet I and others have Fay's Prolific totally distinct from the variety there described, and superior to it in some respects. On another occasion I may have something more to say about the varieties of Currants, but I wish to satisfy myself on a few points first in the hope that my observations may be of service.

In the meantime, I have not found anything better than the following:—Red Currants: Raby Castle, Fay's Prolific, New Red Dutch, and Red Cherry. White Currants: White Dutch. Black Currants: Baldwin's and Black Naples.—Fruit Grower.

[In July of last year Mr. Becker of Jersey exhibited at the Drill Hall a new Red Currant named The Comet to which the Fruit Committee of the Royal Horticultural Society attached an award of merit. The variety is remarkable, as may be seen in the woodcut (fig. 29), for the length of the bunches of fruit and for the size of the individual berries. One noted fruit grower asserts that The Comet is synonymous with Fay's Prolific, and perhaps our esteemed correspondent will give his opinion on this point. The illustration is exactly life size.]

VEGETABLES FOR HOME AND EXHIBITION.

Root Crops—Beetroot and Carrots.

In a former article I mentioned the names of a few famous vegetable growers and exhibitors, and it is to such produce as is shown by them that I would draw the reader's attention. It would be impossible to see the straight, clean, and perfect specimens of Beetroot and Carrots that figure in large show collections without being struck with the standard of perfection that has been attained in vegetable culture. Sometimes one hears such remarks as the following:—"It's all very well to grow a few vegetables like that for show, but it's no good if one has to supply a kitchen all the year round." Now, that is just where the crucial point comes. Those men who show the best of vegetables have all got kitchens to supply, and it is often out of the beds that provide the needs of the household that the

splendid examples come which grace the showboard. "How is it done?" some may ask. In the first place by a capacity for this branch of horticulture; secondly by sound practical knowledge; and thirdly by favoured conditions of soil and aspect, with close attention to detail in culture and careful selection of the best varieties.

Beetroot as an article of food has advanced greatly in popularity during recent years. Beet enjoys a fertile soil, and on this depends to a great extent the rich colour and sweetness of the vegetable. If grown on poverty-stricken soil even the best varieties will be lacking in quality, though it must be borne in mind that the rooting medium should be made favourable by previous applications of manure rather than at the time of seed-sowing. Soil enriched with crude manure in the spring is an incentive to rank growth and forked ugly roots, therefore it should be avoided. All tap-rooted vegetables are benefited by deep cultivation, so that the roots may strike downwards, and so much the better if the bed can be formed on soil that has been well manured for some previous crop such as Celery. Otherwise the manure used must be of a well decomposed nature and be buried a couple of spits beneath the surface. If the soil is at all clayey greater care must be taken in thoroughly working it in order to get straight well-shaped roots.

There is no advantage in sowing the seeds of this crop too early, as the late frosts are liable to play havoc with the tender seedlings. The second week in April is a good time, having first obtained a fine surface and drawn the drills 15 or 18 inches apart. A distance of about 12 inches should be left from plant to plant for development, and a sprinkling of salt or wood ashes along the rows will prove beneficial. Constant stirring of the surface soil during the summer is no mean factor towards the ultimate perfection of the Beet, as this prevents undue evaporation of the moisture. When the roots are swelling to maturity applications of liquid manure may be given with advantage, or sprinklings of a chemical fertiliser, but it is well not to feed the plants before this time or they are liable to make robust and rank leaf growth at the expense of the roots.

In October, or before severe frost sets in, Beet should be taken up and stored for the winter. In this operation great care must be exercised so as not to bruise or injure the roots, otherwise the colour will be impaired. Do not cut off the leaves, though they may be screwed off with the hand. They are best stored in a cool shed in heaps of sand not sufficiently damp to absorb the moisture from them, though at the same time it must not be dry. A good method is to place a layer of sand on the floor, and dispose the roots in a square, crowns outwards. On these put another layer of sand, and then Beet, and so on till the heap is complete. The sand will conserve sufficient moisture to keep the roots from shrivelling through the winter, and they may be taken from the heap as required.

For exhibition purposes the roots must all be chosen of even size and character. They may be carefully washed, but cutting of roots or fibres should be avoided. For early use the Turnip-rooted or round Beet should always be grown, as it comes in well for the late summer shows, and for the main crop Pragnell's Exhibition, Sutton's Dark Red, Dell's Crimson, or Blood Red may be depended on, though there are several other varieties of equal merit. One important point in favour of Beet culture is that the plants do not suffer much from insect pests or diseases. The foliage being strong and fleshy repels all such attacks, therefore if careful attention is given to details of cultivation there is no other secret in the growing of Beetroot with success.

In reference to Carrots, we have a much wider family than with the former, and one on the whole more difficult to grow. We know the long tapering roots as Long Carrots, those terminating abruptly as Horn Carrots, and others again which strike the medium as Intermediate. Gardeners, practically speaking, produce these roots all the year round, first by early forcing in heated frames, to be followed by successive sowings outdoors. The Long varieties appear to be the most favoured for exhibition purposes, not so much on account of their superior eating qualities as for their appearance, and the perfection to which they may be grown. Straight tapering roots of even size, clean, bright coloured, and without a blemish are what the exhibitor aims at, and to obtain these he must have suitable varieties, and subject the plants to careful treatment in cultivation. Good Carrots play no small part in a collection of vegetables, and if they can be shown with the foliage attached this adds to their attraction. I do not care for the practice of scrubbing the roots till they shine like new bricks before putting them up for show, though this may be done to enhance the colour. Grub-eaten or speckled roots are passed over as defective, and if the dirt is removed by washing that is all that is required.

In preparation for the main crop much the same remarks as made for Beet are applicable. Recently broken up pasture land is often disastrous to the Carrot crop, as it is almost invariably infested with wireworms. Where these pests abound a winter dressing of gas lime at the rate of about half hundredweight to the rod, allowing it to lie on the surface about six weeks before digging in, is a good remedy. Salt may also be applied in the spring at the rate of about 7 lbs. to the rod, but perhaps the best advice is where practicable, Do not grow Carrots where you know wireworms abound. Sandy soil is favourable for Carrot growing, and if at all stiff or binding it is rendered friable for sowing by thoroughly breaking and pulverising with the fork.

For sowing the oft-given advice to choose a dry day and dispose the seeds thinly may well be followed. With specially cleaned seeds now obtainable there need be no difficulty in sowing; but where such is not to hand the seeds should be rubbed between the hands with a little admixture of dry sand, or it is hard to sow with regularity. For the Horn varieties a distance of 10 inches may be given from row to row, and for the long-rooted sorts allow 12 to 18 inches, according to the condition of the soil. One of the deadliest enemies of the Carrot is the grub, which often plays havoc to the crop. The larvæ of this pest is secreted below the surface of the soil, whence it emerges, and the fly hovers round, depositing her eggs on the foliage. When hatched the grubs make their way to the roots, and the results need no recapitulation here. A good preventive is to blacken the ground with fresh soot before drawing drills for the seeds. Another plan is to mix a quart of paraffin with a bushel of dry sand and spread it on the surface between the rows, as the smell from the paraffin is distasteful to the fly. If these remedies fail seed of an Early Horn variety may be sown at the end of July, as by this time the insect season is over, and there is yet time before the winter for the roots to mature. Thinning should be done early and in damp weather, leaving the plants from 8 to 12 inches apart, according to the variety.

Fig. 29.
Red Currant The Comet.

A common method for obtaining long straight roots solely for exhibition purposes is to insert a crowbar or other sharp pointed instrument into the ground to a depth of 2½ feet. Fill this with old potting soil with an admixture of dry fowl manure and sow the seeds of an approved variety on the surface. When large enough thin these to one, and during the summer give occasional applications of liquid manure and surface sprinklings of chemical fertilisers. The roots will strike into the prepared compost, and going down straight fine specimens may be thus obtained. An occasional surface sprinkling of an approved fertiliser will assist the main crop, and waterings with liquid manure during periods of drought will also be serviceable. Keep the surface soil stirred with the flat hoe and discourage the spread of weeds.

Towards the end of October, when the leaves change colour, the crop may be dug carefully, and stored for the winter in the same way as recommended for Beet, not cutting the tops, but screwing them off with the hand. Care should be exercised in the display of Carrots on the exhibition table, choosing clean even examples. There are numerous varieties of the different types, and for early forcing purposes Carter's Improved Early Horn, Early Nantes, and French Horn may be mentioned. Veitch's Model is a splendid specimen of the stump-rooted type, either for home use or exhibition; and Sutton's New Scarlet Intermediate is rightly a favourite of its kind, and can be thoroughly recommended. Among the giants of the Carrot family favoured by exhibitors perhaps none are more widely grown than Selected Altrincham and Long Surrey, though here, as with other vegetables, the number of seedsmen's strains is so large that it becomes confusing. The successful culture of Carrots opens a wide field for the grower, and offers ample scope to the exhibitor.
—Grower and Judge.

DENDROBIUM FYTCHIANUM.

THERE are many growers of Orchids who are well acquainted with the usual run of Dendrobes of the various kinds or sections of kinds, but who are total strangers to many of the most interesting species, the one cited above as an instance. It has been in cultivation for nearly forty years, yet I think I am right in saying that it is not represented in one out of forty collections. This is a pity, for to say nothing of the charm of variety one gets by growing the lesser known kinds, there are many of them that flower at a season when the bulk of the more popular ones are over.

D. Fytchianum is a very beautiful plant when seen in good order, and is far less trouble to grow than many that obtain more recognition at the hands of orchidists. It is an upright-growing plant, or nearly so, about a foot in height, producing its blossoms in rather slender racemes from the apex of growth after the manner of D. phalænopsis, or the less known D. barbatulum, with which it is sometimes confounded. A dozen or more flowers are produced on each of these, individually about 2 inches across. The sepals, petals, and most of the lip are white, the latter having, in addition to a purplish tint in the side lobes, a delicate fringe of yellow hairs under the column.

In growth and time of flowering it is not so constant as many other kinds, but after a few seasons it keeps fairly steady to its resting and growing periods. But no attempt should be made by drying off or otherwise to force it into a resting or quiet season, when it is apparent by the swelling basal eyes that the fluids are active. On the other hand, by all reasonable means let the treatment tend to a proper routine, as by this the plants are likely to be more satisfactory over a long series of years.

It is a plant that has a wonderful power of recovering itself after ill treatment, and a batch of apparently almost dead plants, when introduced to heat and moisture, will often make good progress. The best position for it is one not far from the roof glass in the East Indian house, or where the usual deciduous kinds thrive. Like these it abhors either a close heavy root run or a large receptacle, and is most at home in small hanging baskets or pans. These must be scrupulously clean when used, as the plant dislikes being disturbed; they should be thoroughly drained and grown in an open but not too rough description of compost. Equal parts of peat and sphagnum moss with small nodules of charcoal and crocks suit it well.

Early in spring great care is necessary with watering, and it is then a little shade is required to prevent the tender young shoots scorching. But even then too heavy material must not be used, as it defeats the end in view by making the growths more tender, and therefore more liable to injury. As the season advances the growth, of course, becomes more solid, and only sufficient shading to prevent injury to the foliage is needed. Young roots are produced at the base of the shoots when the latter are little more than an inch in length, and this is the best time to renew or add to the compost.

I have before mentioned in this direction that top-dressing is not easily carried out without injury to the smaller rooted Dendrobes, so it is well not to leave this part of the work to inexperienced or thoughtless persons. Even with the best care, although the old material is removed with comparative ease, it is different when it comes to bedding in the new, many of the small roots being either bruised or snapped off. To support the growths a few neat stakes are sometimes necessary when repotting, but if the roots are plentiful, and the compost well firmed, they are not always required. Finish the compost to a neat convex line, clipping off all ragged ends of peat and moss, as these if left make it difficult to determine whether or not the plant is dry at the roots as well as having an untidy appearance.

All this class of Orchid is peculiarly liable to be attacked by yellow thrips, once a formidable foe to Orchids, but since the improved methods of fumigation fortunately less to be feared. Still even now prevention is better than cure, and this consists in keeping up a well-balanced temperature, in which neither heat, air, nor moisture unduly predominates, and the plants in good order at the roots. It is the half-starved plants that give most trouble; keep them healthy, and insects are not much to be feared.

The typical D. Fytchianum, as described above, is a native of Moulmein, and the credit of its discovery is due to the Rev. C. Parish, who found it in 1863 growing principally on low trees in the vicinity of water. There is also a pretty variety called roseum, which is of more recent introduction. This has bright rosy sepals and petals, and the same colour continued about the front portion of the lip. The base of the latter is a beautiful deep purple that is visible through the hairs on the base. It comes from rather a different locality from the type, and was discovered by Major-General Berkeley.—H. R. R.

CHEMISTRY IN THE GARDEN.

(*Continued from page* 187.)

CHEMICAL PROPERTIES OF SOIL.

ABSORPTION. — We have already learnt something about the absorption of water by soils, but as they are capable of absorbing other substances, we will devote a little time to a consideration of what these are.

One of the chief chemical properties of a moist fertile soil is its power to absorb ammonia from the atmosphere. Heinrich carried out some very interesting experiments, to see approximately how much ammonia an acre of land absorbed from the atmosphere in the course of a year. He found that while the rain only brought down to an acre of land 6 lbs. of ammonia per annum, some soils were capable of absorbing 30 lbs. from the atmosphere, which would be equal to about 200 lbs. of nitrate of soda. Some soils have greater power than others, which is no doubt due to the larger amount of oxides of iron and alumina they contain; thus clayey soils are generally those which absorb the maximum amount. The quantity and distribution of ammonia in the atmosphere will be dealt with more fully when we come to consider the air as a source of plant food.

We might carry out with ease a simple experiment to show that soils will absorb ammonia. Fill a 3-inch pot nearly full with sifted soil and press it in moderately firm, then place the pot over a tumbler and pour ammonia water into the top of the pot until it runs through the hole at the bottom into the glass. When the liquid has passed through the soil, put a small piece of unslaked lime into the tumbler, and if the experiment has been carried out carefully no ammonia will be emitted from the liquid, because it has been absorbed by the soil. Different soils may be used in this experiment, and by using the same amount of liquid ammonia and lime the experimenter will soon learn which soils have the greatest absorptive power.

Many practical gardeners use liquid manure for occasionally damping down vineries and Cucumber houses, and also place carbonate of ammonia in the evaporating troughs, the idea being that the leaves will absorb the ammonia which is given off into the atmosphere, thus helping to stimulate their plants. Is it not more probable that the soil in which the plants are growing absorbs the ammonia, and after it is converted into nitric acid the plants take it from the soil by means of their roots?

Soils are able to absorb colouring matter held suspended in water, and also salts from solutions poured upon them. Take a 5-inch pot and fill it with sifted soil, and after pressing it down firmly pour very gradually about a pint of the dark coloured liquid which may be found running from the manure heap. When the liquid has passed through the soil it runs out perfectly clear, showing that the soil has retained the colouring matter of the manure water. It is this retentive property of soils that makes them able to extract the sewage from the water, and allows only the clear liquid to run into the drains, the sewage, like the colouring matter in manure water, being retained by adhesion to the soil particles. If water in which enough common salt has been added to make the liquid taste salty be poured upon a pot filled with soil, it will be found that the water which runs through is almost, if not quite tasteless, showing that soils are capable of absorbing salts.

Soils have also the power to decompose certain salts, in some cases retaining only the acid, while in others the acid and base may be retained. As we shall be continually using the words acids, bases, and salts, more especially when we come to deal with manures and plant nutrition, it would be well to try and learn at once what is meant by these terms.

Purchase some red litmus paper from a chemist. Place a piece of unslaked lime in some rain water, and after allowing it to stand for a few hours pour off the clear lime water into a glass bottle. Put a little of this into a saucer, and then dip the red litmus paper into the liquid, when the paper will immediately turn blue. If instead of the lime liquid ammonia, caustic potash, soda, or magnesia had been used, the action of the litmus paper would have been the same—*i.e.*, it would turn blue when put in water containing any of the above-named substances. One of the characteristic properties of a base is its power to turn red litmus-paper blue, and the bases we shall have to deal with are lime, ammonia, potash, soda, and magnesia.

Procure some nitric acid or hydrochloric acid (spirits of salts) and pour a little into water. In the acid water place a piece of the red litmus paper, and note that its colour does not change. Take the piece of blue litmus paper out of the lime water and put into the water containing the acid, and you will observe that the blue

immediately turns red. The power to turn blue litmus paper red is one of the characteristic properties of all acids. But now we come to the question—namely, What is a salt? A good illustration of a commonly known salt is nitrate of soda. If a small quantity of this salt be dissolved in water and red litmus paper be put into it no change of colour will occur; if blue paper be used instead of the red the solution will not alter the colour.

A salt then has not the power to turn red litmus blue, or blue red. Place a small piece of caustic soda in some water, and after it has dissolved put in a piece of red litmus paper, the colour immediately turns blue; now add nitric acid—one spot at a time—to the caustic soda solution until the blue paper begins to alter in colour. If this experiment be conducted with great care a substance said to be neutral will be formed in the water, which will neither turn blue paper red, nor red blue. What then has occurred? The nitric acid (an acid) has chemically combined with the soda (a base) to form nitrate of soda (a salt). If sulphuric acid or phosphoric acid had been used instead of the nitric, sulphate or phosphate of soda would have been formed; or if potash or lime had been used instead of the soda, nitrate of potash or lime would have been formed. If the presence of the nitrate of soda be doubted, allow the water to evaporate, when the crystals of salt will be found in the bottom of the vessel used.

Before leaving this subject we might quote a practical case in which the neutralising of acids takes place. Peaty soils, and those which have been dressed for a long time with farmyard manure, get sour. Why? Because owing to the decomposition of the decaying vegetable matter acids are formed. What do we do to make these soils sweet? We apply lime, which is a base, and this combines with the acids and forms neutral bodies called salts.—W. Dyke.

(To be continued.)

THE DECADENCE OF WALL FRUIT CULTURE.

Among the numerous readers of the *Journal of Horticulture*, I trow there are many who have studied closely the sweeping assertions of "A Traveller" on the decay of gardening (page 170), but few, I think, will entirely agree with the remarks there made in so fluent and polished a style—a style that betrays the "Traveller" to be also a scribe, whose thoughts may often linger upon the achievements of the past, yet do not prevent him from being up to date in the matter of wielding the pen of a ready writer.

I do not intend to take up the cudgels on behalf of the "smart" gardener of modern times, but it has struck me that if the notes of "A Traveller" are productive of no other good, they have already done yeoman's service in bringing out the instructive leader of "Invicta" (page 185), whose thoughts have evidently been directed to the subject that heads these notes by the forebodings of "A Traveller." Fortunately "Invicta" goes somewhat deeper into the matter, for while he admits that good examples of wall fruit culture are not so numerous as formerly, he also endeavours to find some tangible reason why such is the case. A weighty one advanced is "that with the great facilities now at hand in the way of glass protection, Peach growing in the open air is practically unnecessary."

There is, without doubt, a great deal of truth in such an assertion, but, in my opinion, it does not show a sufficient reason why Peaches should not be grown on outside walls as largely and well as ever they were, not only with the object of prolonging the season, but of giving a more plentiful supply. Choice fruit is always in demand, and there are very few gardeners in the enviable position of having too large a supply of really good fruit. The bedding craze when at its zenith was doubtless answerable for the decadence of many phases of gardening, as so much labour was needed to raise, plant, and tend the enormous quantities of plants required for large flower gardens, that many details which help to promote high culture in other directions were of necessity neglected.

The old stereotype bedding craze is, however, rapidly passing away, and many hardy, or more easily raised, yet not less beautiful plants are now used for the embellishment of the flower garden. If, then, this form of gardening has in the past been to a great extent answerable for the decadence of wall fruit culture, matters should begin to improve now that we have returned to a simpler style of bedding; yet I question very much if such will be the case. If I am right in this assumption, it shows clearly that there must be some far-reaching cause which has brought about a state of affairs so much to be deplored. It is sheer nonsense to pretend, as some of the pessimists do, that present-day gardeners do not possess the skill to grow and train wall trees in the way that their forefathers did. The way in which Peaches and other fruit trees are grown, trained, and fruited under glass clearly combats such arguments. At no time in the history of gardening were better crops of fruit more generally grown under glass than they are to-day. How, then, our detractors will again ask, do you account for the fact that such a satisfactory state of affairs does not exist in regard to wall trees? Perhaps you will take shelter under the well-worn argument of the unsuitableness of our climate. Assuredly I am not, for although our climate may be by no means perfect, it is good enough to enable cultivators in the southern and midland counties to produce fine crops of Peaches three years out of four when cultural details are well carried out, but to do so a great amount of intelligent labour must be given to the work.

On this the whole matter hinges, for it is the great drawback in the majority of gardens of to-day. It is absolutely impossible for gardeners in many places to bestow the necessary amount of attention to their wall trees, and the inevitable result is that they gradually drift into an unsatisfactory condition. Time was when in many well-conducted gardens a regular hand—who had been trained from boyhood to the work—was placed in charge of the wall trees. His first consideration was to give the trees whatever attention they required at the right time, and only when this had been accomplished was he given other work. How do matters stand in this respect to-day? Why, the man who in former times had little else to do but attend to the wall trees, is, in consequence of a shortness of hands, set to do other, and as far as times go, more pressing work, while the trees are going to ruin through unavoidable neglect.

When we come to the point of deploring the loss of the beautifully trained trees of olden times, I think we may rather congratulate ourselves that we have been able to adopt practices more suited to altered circumstances.

A properly trained tree is, I admit, a beautiful object, and I yield to no one in my admiration of a well-balanced fan-shaped tree, in which every angle is a correct one, but they are expensive objects of beauty, which gardeners can scarcely afford to grow in these utilitarian days, for much labour is needed to keep them in the best of condition. And yet I think no one will deny that, given an equal amount of wall space for two trees, one to be trained and kept in perfect shape, while the other was being manipulated on less methodical lines, that the latter system would be productive of the best results in the shape of fine fruit in quantity. If we must have some perfectly trained trees in our gardens to show that the art of producing them is not lost, let them be grown in prominent positions where they will catch the "Traveller's" eye, but by all means let plenty of others be grown on less rigid lines—to supply abundance of fruit.

To sum up the matter, I for one cannot admit that gardeners are to blame for the present condition of the wall trees in this country, for during the last twenty years a great reduction of the hands employed in gardens has taken place, barely enough being left to keep places in presentable condition by doing what I term "surface gardening." Under such circumstances some things must be neglected, and the gardener who in choosing between two evils makes a point of keeping down weeds and maintaining cleanliness and order as far as possible—even at the expense of his wall trees—follows, I think, the wiser course. The requirements of employers are much greater than they were twenty years ago. Let us take for example places where the same number of men are employed now as formerly, and then compare the amount of time taken up in carrying out plant and floral decorations in the mansion, and then wonder, if we can, why certain phases of gardening compare unfavourably with the achievements of long ago. Nine gardeners out of every ten are thoroughly cognisant of these facts, and when they meet in a body at some great show freely discuss the "curse of modern gardening"—viz., reduced hands and increased house decorations. Yet they seem to have great temerity in writing plainly to that effect in the horticultural press. It is a matter well worth ventilating, and I should like to see a vote taken among the gardeners of Britain as to what, in the opinion of each, is the cause of "the decadence of wall fruit culture."—H. D.

HOME-MADE WINES.

(*Continued from page* 187.)

Elder Wine.

The fruit of the Elder contains a considerable quantity of fermentable matter, which is essential to produce an active fermentation, and its beautiful colour gives wines a rich tint, but it is defective in saccharine matter. It is much improved by adding a small quantity of argol. Dr. MacCulloch recommends 1 to 4 and even 6 per cent. according to the greater or less sweetness of the fruit; the sweeter the fruit the greater the quantity of argol required.

To every gallon of Elder berries take 1 gallon of water; but before adding the water the berries are to be bruised and allowed to remain in the juice till the following day, when they are to be boiled in a copper for ten or fifteen minutes. They are then to be pressed and strained through a sieve. The given quantity of water is to be poured upon the pressed fruit, the whole well stirred and then pressed and strained, which is to be added to the juice. Measure the liquor and test its gravity by the saccharometer, and bring the gravity up to 120, which will require 3 to 3½ lbs. of sugar per gallon; and to

each gallon add 3 ozs. of ground ginger and 3 ozs. of allspice. Boil the water half an hour and then strain it into the fermenting tub.

When cooled to 5° Fahr. add 1 oz. of argol to the gallon, previously dissolved in a portion of the liquor, and also add yeast on a toast. Test the gravity again by the saccharometer, and if it is below 120 raise it to that standard by the addition of sugar, and stir the whole, agitating it freely. When the gravity is reduced to 90 by fermentation it is to be put in the cask and the fermentation encouraged till the gravity is reduced to 50 or 60. Care must be taken to keep the cask quite full to the bunghole to enable the wine to throw off its impurities, and when the fermentation has ceased rack it off, cleanse the cask with hot water, and return the wine to it while the cask is warm, fill it up to the bung, and let it remain in the cask twelve months before bottling it.

2, The following recipe, which we had from a lady in Gloucestershire who made a wine of very excellent quality, will, if followed, give a fine wine:—To every gallon of Elderberries put 4 quarts of water and stir them every day for a week. Boil the whole for half an hour, then strain off the liquor, and to every gallon add 3 lbs. of sugar. Boil it again for half an hour, skimming it well all the time, and to every 6 gallons add 1 lb of ginger, 2 ozs. of allspice, and 1 oz. of cloves. Let it stand in an open vessel till it is blood-warm, and then work it with yeast on a toast. In three days put it in the casks.

3, Another very excellent recipe which we have practised for several years produces an Elder wine of very superior quality. Boil ten gallons of water, and when cold add 10 lbs. of raisins cut or chopped small. Let them ferment for ten days, stirring them twice every day. At the end of the ten days strain the liquor through a flannel bag, and add to three quarts of the juice of Elderberries a little juice of Sloes. Put the whole into a cask, and add 3½ lbs. of moist sugar, and a quarter of an ounce of isinglass dissolved in a little of the liquor with a pint of brandy. Let it stand for three or four months, and afterwards bottle it.

Parsnip Wine.

Take 125 lbs. of well-grown sound Parsnips. Scrape and wash them thoroughly. Cut each root into four longitudinal pieces, and then cut these into pieces 3 inches long. Put them into a boiler with 25 gallons of soft spring water, and let them boil for an hour and a half without bruising the roots. Then strain the clear liquor through a fine sieve into the fermenting tub, and after testing its gravity add immediately 1 lb. of powdered argol previously dissolved in the liquor, and bring up the gravity by the addition of sugar till it stands at 120. When the liquor has cooled to 80° or 85° add a pint of good brewers' yeast, then cover it up with a flannel cloth, placing a board over to keep it close.

Stir the liquor every day, and test its gravity till this is reduced to 90 or even 80 of the saccharometer. At this stage take out 2 quarts and warm it to the degree of 90 by the thermometer, and add to it a quarter of a pint of good brewers' yeast. In the meantime skim off the frothy head of the must in the fermenting tub, and preserve it in a bottle for future use, and then add these 2 quarts of must and yeast to the mass.

Prepare an 18-gallon cask by well washing and scalding it; and while yet warm strain the liquor into it, filling it to the bung, and let it work over, adding to the loss with liquor reserved for the purpose. As soon as the hissing ceases bung it up close, and have a vent-hole which can be opened at pleasure, but which it is desirable to close as soon as possible.

March is the best month for making Parsnip wine. In December it should be racked, and in the March following it should be fined for bottling.

Rhubarb Wine.

This is a very palatable and good wine when properly made, but on account of the quantity of oxalate of lime it contains it is injurious to constitutions that have a gouty tendency. This is not the place to enter into a medical view of the case, but we would recommend those who wish to indulge in the use of Rhubarb wine as a beverage to consult their medical attendant before using it.

To make 10 gallons of Rhubarb wine take 60 lbs. of the stalks of the leaves of Rhubarb unpeeled. Cut these in pieces and bruise them with a mallet, or pass them between rollers, such as a wringing machine, without cutting them. Put them in the fermenting tub, and pour 5 gallons of cold water over them, leaving them to macerate for twelve or sixteen hours; then press the whole, returning the juice which has been expressed to the fermenting tub. Add 30 lbs. of sugar, or as much as is necessary to raise the gravity to 110 if a sparkling wine is desirable, and to 120 if a still wine; also 4 ozs. of powdered argol, and enough water to make the quantity of liquor up 10½ gallons. Cover the tub with a blanket, and place it in a temperature of 55° or 60°. Stir it occasionally for three days to encourage the fermentation, and then strain it through flannel into a cask, which must be kept full to the bung till fermentation ceases. As soon as the gravity of the wine is reduced to 40 the cask may be removed to the cellar and the bung fixed firmly in.

In a month or six weeks the wine may be fined and drawn off into a clean cask, or returned to the same one after being properly cleaned. The cask may now be finally stopped close and left till the time of bottling. If a sparkling wine is desired it must be bottled in March following, with the corks safely wired; but if a still wine it should remain in the cask at least a twelvemonth before being bottled.

(To be continued.)

SIXTY YEARS' PROGRESS IN HORTICULTURE.

While we all acknowledge the wonderful strides in other arts and sciences, of which we have been reminded so much of late, I claim that the science of horticulture with which we are all so closely connected can lay a fair claim to a share in the improvement of our country. Fruit, vegetables, and flowers, as food for the body and gratification of the senses, form a very important element in the necessities of life. When we compare our resources now to what they were sixty years ago we wonder how our forefathers lived, worked, and battled as well as they did. The changes and improvements in the method of production have been so great, and the varieties that have been introduced so numerous, that I am afraid I shall have to omit many important items that might be dwelt on with advantage, or I shall occupy more time than can be allowed.

Fruits.

Nothing is so noticeable in the gardener's career as the decline in the cultivation of the Pine Apple. In the olden times it was the gardener's ambition to be able to grow and fruit a Pine Apple, and keep up a succession by the aid of varieties like the Queen for the summer, and the Smooth Cayenne and Black Jamaica for the winter. The bark from the tan yards supplied the fermenting material in which to plunge the plants, while pits for the suckers and the succession plants, with houses or pits to fruit them in, were considered a necessity in all aristocratic establishments. Now, however, the introduction of steam has brought Jamaica and other foreign climes within touch of the mother country, and fruit can be brought in such good condition so quickly that it is only in the very old establishments that Pine growing is carried on to any extent.

There is no doubt the cultivation of Grapes has been a very important feature during the period under notice, and when Sir Robert Peel took the duty off glass little could he have foreseen the very great advantage it would prove to the cultivation of Grapes and other fruits, vegetables and flowers. Since that time, and particularly in the last twenty-five years, Grape growing for market has developed enormously. We read of one place alone having 20 acres of glass houses, from only one of which structures 7 tons of Grapes have been cut in one season, while from the whole 100 tons of Grapes went to market. Mr. George Munro, the great salesman of Covent Garden Market, had 22 tons through his hands in the four days preceding Christmas, 1896.

Of the varieties Black Hamburgh and Muscat of Alexandria were in existence at the beginning of the Victorian era, but we can lay claim to many introductions of good serviceable keeping Grapes which prolong the season. Notable amongst these are Alicante, introduced rather more than thirty years ago; Lady Downe's Seedling and Foster's Seedling, Gros Colman, Madresfield Court, Gros Maroc, Buckland Sweetwater, and Duke of Buccleuch. Then we must not forget two good Grapes raised in the Isle of Wight by Mr. Myers, late gardener to Mrs. Hutt, Appley Towers, only a few years ago. One of these, a black variety named Appley Towers, will, I believe, be grown largely for market as a good late keeping one.

The cultivation of Peaches and Nectarines has developed remarkably of late years, and to Mr. Thos. Rivers of Sawbridgeworth belongs the honour and credit of introducing some fine varieties. A luscious Peach or Nectarine of the best quality is always acceptable, and is very highly appreciated by most persons.

Something wonderful has been accomplished in the culture and development of the trade in the king of fruits, as Apples are sometimes called, both at home and in our Colonies. Although they have been grown in some fashion or other for centuries, it is within the last thirty years that extra attention has been directed to the improvement in culture and varieties and the uprooting of many worthless sorts. The favourite plan of training in the olden times was espaliers, but they are gradually dropping out of fashion, although the cordon style, which is but a modification, is adopted by way of change in many establishments. There were some very good Apples at the beginning of the Victorian era. Cox's Orange Pippin and Blenheim Orange were introduced prior to 1837, but such splendid varieties as Lord Suffield, Potts' Seedling, Bismarck, Lane's Prince Albert, Bramley's Seedling, Lord Derby, New Hawthornden, Newton Wonder, Gascoyne's Scarlet, and Worcester Pearmain are all valuable additions during the period. Pears have also been improved by the addition of such sterling varieties as Doyenné du Comice, Pitmaston Duchess, Beurré Superfin, and many others.

Plums, again, have been augmented by Monarch, The Czar, Grand Duke, and the Early and Late Transparent Gage, each of which is of the first merit. The old Green Gage, one of the most delicious of fruits, was already in cultivation, and so I believe was Victoria, under the name of Sharpe's Emperor, but in 1844 it was introduced as a new variety

under its present name. One cannot claim for Cherries the improvement that is manifest in other fruits. The gumming and canker to which the tree is so subject has rather disheartened the growers, and many of the old Cherry orchards are dying out, although there are still some very fine ones about the country. Gooseberries, Black and Red Currants, as well as Raspberries, have kept pace with the times, and many extra fine varieties have been added to the list.

The cultivation of Strawberries has risen by leaps and bounds, and we can claim all the existing varieties to belong to the period of her Majesty's reign. I remember the Hautbois, the Elton Pine, Myatt's Eleanor, and British Queen in my younger days. Now we have such splendid ones as Royal Sovereign, Sir Joseph Paxton, Laxton's Noble, President, Sir Chas. Napier, James Veitch, La Grosse Sucrée, and Waterloo, all with strong constitutions, grown in fields by the hundreds of acres. More speculators than one are making a large commercial transaction in the cultivation of this wholesome and delicious fruit. Here in Hampshire, at Botley and Sarisbury, and also at Swanley, in Kent, and in some parts of Berkshire, acres are cultivated, and tons of fruit despatched by special fruit trains to the large provincial towns in the Midland and North of England. As many as 11 tons have been despatched from Swanley Station by one individual grower in one day. When we come to consider the circumstances connected with the cultivation and consumption of the fruit one can then realise to a certain degree its benefit to the community. The labourers in the fields, the basket makers, the salesmen, the hawkers, the jam factories, the glass and stone ware jar manufacturers, have all a share in this comparatively new industry.

Vegetables.

I shall not attempt to enumerate the many new introductions in the various classes of vegetables. It must be sufficient to say that the gardener of to-day has something better to work on than he of the past generation. The old grower, while digging and storing his smooth and polished White Beauty, Snowflakes, Supremes, or Ashtop flukes, cannot but recall the difference between these and the Pink-eyed Never-blows, Gold Tops, Dalmahoys, Rocks, and Champions of his younger days. In Broccoli and Cauliflowers that grand variety Veitch's Autumn Cauliflower, and their Self-protecting Autumn Broccoli, fill gaps from October to January or February that used to be void. In Cabbages the old Plaws and Early Battersea are superseded, although the old Nonpareil and Early York are not to be despised. Of Kidney Beans the Duns and Speckled Duns – so called by the colour of the seeds – have given way to the Canadian Wonder, Ne Plus Ultra, Improved Negro and others, and so on through all classes improvement has taken place.

The increase in the cultivation and consumption of Tomatoes during, say, the last thirty years is beyond conception. When I was a lad the American Red, a wrinkled variety, used to be cultivated by a few persons, and the fruits sometimes used in stews, or as an entrée stuffed with Mushrooms.

Subsequently it was discovered they made an excellent sauce, and later some tried them in salads, until the taste has gradually developed and they are now consumed by tons; whereas thirty years ago they could be reckoned by pounds. Miles of glass is utilised throughout this country for the indoor cultivation of this vegetable, and tons of fruit are also grown out of doors in favourable summers, not only by market growers but by the cottager and artizan, as well as the villa gardener, all of whom have acquired a taste for the juicy Tomato.

Before I leave this part of the subject, by the kindness of Mr. George Monro, the eminent salesman of Covent Garden, I am able to give some interesting particulars regarding the sales of home-grown garden produce. The following is a copy of a letter with which he favoured me, and came to hand after writing the above portion of my paper:—

Buxton, Derbyshire, August 5th, 1897.

Dear Sir,—Yours to hand. Being away from London I can only give you a few figures, which you can use in any way you like, and I may say that they only relate to my own business, and do not represent the total received on the markets during the time mentioned. Grapes have increased more than any fruit. The total we sold in four days before Christmas, 1896, was over 22 tons weight, and that would be about double the average during the remainder of winter. Tomatoes often run to 4, 5, or 6000 baskets daily, averaging 12 lbs. each. The next great increase of late years is in Cucumbers, as we often sell over 2000 hampers daily, averaging about 3 dozen each. At one time our market was mainly supplied from Holland, but we have turned the tables on the foreigners in these, and I alone exported during last winter and spring thousands of hampers, which went to different parts of the Continent, including Vienna and St. Petersburg, as ours being so much superior to the Dutch leaves room for great extension until they learn to grow them better. I also send Grapes regularly to the Continent, and in the winter to America. Only a tithe of what we receive is consumed in London. As quantity increases we have to find outlets, and must go further afield, as growers now put up houses by the hundred.—Yours truly, (Signed) Geo. Munro.

The above particulars, coming from the fountain head, we must acknowledge are reliable and enlightening, and although this is from one who is known as the leading man in Covent Garden there are scores of others either directly on indirectly engaged in the same pursuit, and a slight consideration would give one a little idea of the enormous increase in the production and consumption of home-grown fruits and vegetables during the Victorian era.—(*Paper read by* Mr. C. Orchard, *Bembridge, at the Ventnor Institute, on August 7th.*)

(To be concluded.)

TOMATO NOTES.

Fruit Ripening.

In reply to "W. R. Raillem" (page 176), I have not made critical comparisons from an epicurean standpoint as to the relative merits of fast-ripening Tomatoes cut and finished on a warm sunny shelf, and those absolutely ripe gathered from the plants. If I did do so in the months of July and August, the difference I imagine would be very slight, but probably in favour of the fruits freshly gathered. Later on in the season, or say after the middle of September, I would not expect the flavour of artificially ripened Tomatoes to reach the quality of those taken direct from the plants.

I readily admit that to ascertain the true and perfect flavour in Tomatoes they should be gathered and eaten direct from the plants. This is an indisputable fact, which I do not wish to deny, because I can assure "W. R. Raillem" that is the method I should adopt myself if I were to consume Tomatoes largely in a raw state. The eating of freshly gathered fruit is the best way of acquiring a taste for Tomatoes.

"W. R. Raillem" will see, therefore, that I do not dispute the fact he lays importance upon, but I think for ordinary purposes Tomatoes can be finished off the plants, thus relieving the latter of the burden, and still be of good flavour to be useful, especially for culinary purposes. I think the majority of private growers, leaving out those who grow for sale, would endorse my statement if it were qualified by limiting it to the months of July and August.

My chief reason for recommending gathering prior to full ripeness was utility – relief to the plants, which could extend and set more fruit, as well as the prevention of the fruit cracking which was already ripening. The latter evil may be largely averted on the plants that have completed their growth and no more fruit is required to set. A drier condition of the soil will then be favourable to ripening of the fruit, and a check to the tendency shown for cracking.

There is a considerable difference in the flavour of even ripe Tomatoes direct from the plants. In my opinion large fruits are not so perfect in flavour as smaller examples. The most delicious, I think are the Plum-shaped and small round varieties, either red or yellow, for eating direct from the plants.

Tomato Roots.

"S. S.," on page 176, submits the question, "What are the proper means of inducing a constant multiplication of healthy rootlets in the early and other stages of growth?"

In the first place Tomatoes raised from seed require to germinate in light, sweet, and sandy soil. The seed ought not to be sown too thickly. If the seedlings when they appear have not less than an inch of space they will not suffer from overcrowding before ready for moving. Plenty of light and a free circulation of air is absolutely essential to maintain a sturdy character, thus laying a firm foundation for free rooting afterwards. Immediately the seedlings are sufficiently strong and advanced in size transplanting into small pots is necessary, using a good but light and sandy compost.

At this point commences the first stage in the increase of roots and rootlets. Each seedling plant is sunk so low in the pot as to bury the whole length of stem, leaving only the leaves resting on the surface soil. The advantage of having the little seedlings strong by exposure to light is apparent now, because when developed under the above mentioned favourable conditions the whole length of stem is ready to emit roots when buried in the soil. This is of great advantage in promoting growth that will be highly satisfactory. If the next shift into larger pots is carried out on a similar principle, burying as much of the stem as possible, a further increase of roots takes place. The plants must, however, continue to receive abundance of light and air so as to modify the growth and prevent elongation, which would weaken them considerably.

In the final potting or planting out the same principle of burying a portion of stem is continued. After this, however, the plants cannot be moved further, so in due time when it is necessary to increase the rooting power, which will be required when the first bunches of fruit have set and are swelling, top-dressings of rich soil are placed on the surface, a couple of inches depth at a time sufficing. This necessarily surrounds more of the stem with soil, and fresh roots therefrom are encouraged. The older roots ramifying in the soil below are induced to emit rootlets into the freshly added material. By continuing these additions as the rootlets come to and whiten the surface considerable impetus is given to the setting and swelling of fruit as well as the general vigour of the plants.

All this attention and encouragement to the roots will, I may repeat, be useless without the essential, modifying, and consolidating influence of light. The full day's sunshine is best, but if this cannot be commanded for the whole day allow all the sunshine possible to reach them, and for the rest unobstructed light. Due amount of moisture is an important factor of success, and equally necessary with the other essential conditions. The rule to follow in applying it is to afford sufficient to moisten the whole bulk of soil and roots whenever required, then to wait until more is required. Much depends on the correct application of water in encouraging the multiplication of roots and rootlets.

Plants treated as indicated become a perfect networks of roots, which must have more support than clear water and top-dressings can fully supply, especially when the treatment has been successful and good results have followed. Recourse must then be had to small dressings of artificial fertilisers, and applications of liquid manure and soot water, as the readiest available stimulants and feeders.

During the whole course of cultivation, firm potting in pot culture,

even to ramming the compost hard at the final potting, and well firming the soil about the roots in the planting-out system should be adopted. This is a very important means of inducing the roots to be fibrous and abundant instead of coarse and few.

I trust I have made the matter sufficiently clear to "S. S.," but if any point requires further explanation I shall be glad to enlarge upon it again with the Editor's permission.—E. D. S.

Tomatoes at Malshanger.

Because so many diversely named Tomatoes are sent to the Drill Hall for the notice of the Fruit Committee, and these, as a rule, are so much alike to others already well known, I always make it a rule when visiting gardens to see the Tomato house, and there gather ideas as to the general quality of the stock grown. Without doubt, nearly everybody has good stocks. Nothing is easier than to either purchase seeds of the best or to save one's own from the very best fruits and plants. Mr. Kneller does this at Malshanger, and his span house of plants the other day showed not only as heavy a crop as could be consistent with the fact that the fruits were gathered as fast as they ripened, but the sample was of the very best form that can be furnished anywhere. The stock is of the Perfection type, and being specially selected to improve it was put into commerce as Plentiful, and it is both perfect and plentiful.

The plants were placed in 3 feet long boxes in the house early in April, and beyond having produced as heavy a crop as any similar plant could do, would carry yet an abundant one until the houses had to be filled with other things late in the autumn. Nothing well could be better, and therefore it is hard to see in what direction new varieties can excel it. We do not want big or ungainly fruit. Merely prolific varieties are practically out of the question. We could do generally with richer flavour, and that seems to be about all the room there is for improvement. In this case the boxes, 3 feet long, were 13 inches wide inside, and beyond rubble and moss at the bottom had but 6 inches of soil in them. The plants in each box were three. No doubt at all, restricted root area, good drainage, and good sweet loam give the best crop results and least disease.—A. D.

ANNUALS FOR AUTUMN SOWING.

Many hardy annuals that are seen to comparatively indifferent advantage when sown in spring are very effective, and in some cases, valuable for cutting in the early summer months, from seed sown in September. The spring weather, with its accompanying array of slugs and other pests, does not always favour the germination of the seeds, and if it do the gentry lurking in the ground make the most of the opportunities and eat off crop after crop of tender seedlings.

Everybody knows that most of our so-called annual wild flowers or weeds are biennials—that is, the seeds germinate during the first moist weather after they are scattered and the seedlings survive the winter under favouring conditions, producing the finest flowers and the most plentiful amount of seeds in the early part of the summer following. The plants get a good grip of the soil during the late summer and autumn months, and in spring, after the snow that has protected them from the wintry blast has gone, have nothing to do but develop the leafage in gleams of sunshine and soft glowing moisture, the roots supplying abundance of nutritive elements, and the plants themselves sturdy, hard in tissue, and unpalatable to newly hatched slugs and even older molluscs.

Thus the self-sown late summer annual has the whole spring and summer before it, being in fact the sturdiest and most vigorous of the race, and as such most prolific of flowers and seed. This means a selection of subject suited to environal conditions and an accordance with natural adaptation to circumstances. That in two ways—(1) The plants themselves, and (2) the individual having recourse to them. The latter implies an ardent lover of flowers, bent on having a display from an early part of summer right along by sowing more up to frost without any expenditure in anything but a few seeds. How is it done? Well, there is always something to learn, and the longer one lives the more seen of it—in gardening. An instance may profitably be referred to.

It was in this wise:—A tradesman or mechanic bought a piece of land, built a house, and reserved a large plot of ground on the south side. This land was bastard trenched and manured. The owner was a gardener we opined, and was going to grow Cabbages and Potatoes. But spring came; no such thing took place as setting the plants or seed. Bare land up to Old May Day, yet it was turned over more than once, and at the last turning some fertiliser spread on, and mixed very carefully with the soil by taking small spits. Something was going to be done. There were two or three frames (evidently home-made), and they were seen to be full of young plants—Asters, Stocks, Chinese Dianthus, Scabious, Zinnias, and others. These were put out, and a finer sight was never beheld by any person in August. I do not know what there was not, but it seemed to me that everything worth growing for cutting that could be got out of half-hardy annuals, and some hardy—such as Cornflower, Calliopsis, Corn Chrysanthemums, and Mignonette—were there. The sight by day was delightful, and the smell at night delicious.

There did not appear anything but the useful, nothing that was not bright, and manifestly intended to bring grist to the mill, for the flowers only shone once and disappeared. Roses have got there since then, with Pyrethrums, Pinks, Carnations, single Sunflowers, Cactus and other Dahlias, all things the knife can cut and the hand turn to profit. No glass or any show, but a man, sometimes two, in shirt-sleeves at night or evening, and working like a "brick." Potatoes have got there, but only earlies for a change, as out they go in time for a flower crop. Evidently flowers sell better than Cabbages or "taties"—at least, these are a drug from the allotments, and from repeated cropping with the similar subjects not infrequently very indifferent.

But the foregoing has no connection with our subject only in so far as it shows what way an individual without the means of a Crœsus may work and do by the expenditure of a few shillings in seeds of the kinds most likely to give a return quickly for the outlay, and thus enable him or her to creep before attempting to run.

Well, some of the half-hardy annuals were off in time for sowing hardy annual seeds. The land had no weeds, and beyond pointing in very lightly a dressing of thoroughly decayed manure, the seeds were sown on a comparatively hard and dry ground during the early part of September. "The seeds germinate better then, and are less liable to mildew or damping than at any other time." That also looked like a wrinkle culled from the stores of Nature, but only holds good where the seeding is thin, for moulds delight in the continual moisture of late summer and autumn. Not a great array of sorts were sown, and all in rows corresponding in distance between to the height of the plants, except the first to be named, which were sown in a somewhat sheltered spot, and the seedlings thinned to about 3 inches apart and put out in the final quarters in April in rows 2 feet apart, and the plants 18 inches asunder.

Coreopsis tinctoria, yellow and brown flowers, 2 feet or more. The flowers have good stalks and stand out well among Grasses.

Candytufts, carmine, flowers bright carmine; lilac, soft lilac flowers; sweet scented, white, rather small flowers, but very floriferous; and White Rocket, large trusses of white. All grow a foot high, or rather more.

Centaureas cyanus (Cornflower), blue, and always in demand, as the stalks are long and the flowers anything but stiff. A great breadth of this, and another of the mixed, all colours, mostly white, pink, and parti-coloured, very pretty; 2 feet or more.

Clarkias pulchella, dark rose, 18 inches; and pulchella alba, pure white, 18 inches; sprays useful for cutting, but not many grown.

Collinsias bicolor, lilac and white flowers, 1 foot; and candidissima, white, very free; 1 foot.

Erysimum arkansanum, bright yellow, Wallflower-like; 2 feet.

Eschscholtzias californica, yellow, orange centre; crocea, orange or deep yellow; and crocea alba, white flowers; all 1 foot. Slugs set very little store by these plants, and they have good stalked flowers, which, if cut early, last some time in water, and are very pretty in bud.

Geum atrosanguineum flore-pleno, scarlet, semi-double flowers. Sown in sheltered place, and transplanted in the spring; 2 feet or more.

Godetias rosea alba, white, with rosy centre; rubicunda, rosy crimson; and The Bride, white, rosy carmine centre. Very pretty, and, cut in sprays, very beautiful; all 18 inches. Sown in sheltered spot, and transplanted in spring.

Gypsophilas elegans, light, graceful, elegant spikes of small white and pink flowers, fine amongst grasses as over-tops in vases; 2 feet or more; and rosea, like the preceding, with pink flowers. Give sheltered place, and transplant in spring.

Kaulfussia amelloides, blue flowers; 12 inches; requires sheltered place and dry soil.

Lasthenia californica, bright golden yellow flowers, requires shelter and light soil; 9 inches.

Leptosiphons densiflorus, lilac, and densiflorus albus, pure white; 18 inches; must have shelter and well-drained soil, then give fine trusses of flowers.

Linum azureum, pale blue flowers; 18 inches. This also requires a dry soil and sheltered situation.

Lupinus nanus, blue and white flowers, and nanus albus, pure white, both 18 inches; the spikes of these are very handsome without the coarseness of the perennial species. A large breadth of these Lupins proved very useful.

Nemophilas atomaria, white, chocolate spots; discoidalis, black, white margin; insignis, blue, white centre; insignis alba, white; and maculata, white, veined and spotted with purple. All 6 inches, and for beds or edging excellent where there are not cats. These animals sometimes fawn the plants out of existence, often leaving the plants alone until coming in bloom. Very beautiful in pots.

Nolana atriplicifolia, blue, white, and yellow flowered trailer. Sow in sheltered place, and transplant seedlings in spring. Makes a fine bed.

Platystemon californicus, pale yellow; 1 foot. Must have shelter and dry soil.

Saponarias calabrica, little pink star-like flowers, compact growing; good in beds or borders; and calabrica alba, white; both good for beds or edgings.

Silenes pendula, bright pink, 1 foot or more; alba, white, 1 foot or more; compacta, rose pink, 6 inches; and pendula compacta alba, white; 6 inches. Well known plants for spring bedding, being sown earlier for that purpose, but fine when sown in September for early summer flowering.

Venus' Looking Glass, blue and white; dwarf plants for edgings or beds, very beautiful in early summer.

Virginian Stock, red and white, 6 inches. Both do well in any soil, and very floriferous.

Viscaria oculata, rose colour with crimson eye. In sheltered place and light soil this plant is very beautiful; 18 inches.

Whitlavia grandiflora, bell-shaped violet blue flowers; 18 inches. Requires sheltered place, transplanting in spring.

The seeds should be sown during the first fortnight of September, and in well-drained soil, as it is damp that ruins most of them in the seedling

state, and to get them up and away the soil must be duly attended to in watering, never making it too wet. Another point is to thin the plants so that they stand clear of each other for the winter, and any spare ones then placed in pots, and these plunged in ashes under a wall facing south or other good aspect, will come in finely for window box or other decoration, and from variety alone prove very attractive. The more tender should be moved to the flowering quarters in March or April. Most, however, do well in borders fronting shrubs, and with proper attention give a profusion of bright flowers during the early summer months.—G. ABBEY.

HARDY CLERODENDRONS.

ALTHOUGH most of the species of Clerodendron require a stove or greenhouse temperature, there are two which are perfectly hardy in the southern counties and in favoured parts of the midlands of this country. The species under notice are C. fœtidum, a Chinese shrub, and C. trichotomum from Japan. Both are good late flowering shrubs, and are well worthy of notice.

The habits of the two differ in various respects. C. fœtidum makes a quantity of soft sappy growths each year, which during winter die down to the ground. When growing in fairly good ground the growths average 4½ to 5 feet in height. The leaves are large and handsome. They are cordate, with serrated margins and acuminate apices. The leafstalks are long, and the blades 6 to 9 inches across, dark green above, silvery beneath. The veins are very prominent, and, like both surfaces of the leaf, are thickly covered with purplish hairs. The flowers are rose coloured and produced during the latter part of August and September in large terminal corymbs. The great drawback to this plant is the most unpleasant odour given off when it is rubbed.

C. trichotomum makes a bush 8 or more feet in height, with a large spread. The leaves are light green, and much thinner than the former, but like that the veins are very pronounced. The leafstalk is several inches in length, but like the blade is found to vary considerably on different leaves on the same plant. The blades are ovate and acuminate, sometimes 9 inches long by 6 inches wide, dwindling on various parts of the stem to half that size. The flowers are produced terminally in large loose cymes. The individual flowers are striking in appearance. The calyx, which is made up of five sepals, is angular, the points and margins being red, and correspond in colour with the two bracts which are found at the base of each flower and the tube of the corolla. The free portions of the corolla are white, star shaped, and about 1 inch across. From the mouth of the corolla tube the stamens and style protrude 1 to 1½ inch. The flowering period of this is August and September. An additional recommendation for this is that the flowers are very sweetly scented. A bush in flower makes its presence known several yards away. They thrive in any good soil, sandy soil being preferable to very heavy; liberal top-dressings of farmyard manure will be found beneficial once a year. Both species throw up suckers readily, and can be quickly propagated by division in spring.—D. K.

CULTURE OF HYACINTHS.

Now the bulb season is with us, a few remarks on Hyacinth culture may be welcome to some readers of the Journal. Roman Hyacinths being the earliest, a word or two may be devoted to my system of cultivating these most beautiful early and late flowers. The spikes of white fragrant blooms are charming to see, and are useful in many ways, especially for wreaths, sprays, buttonholes, and all kinds of decorations. Select medium size hard bulbs, as I find these start more freely than larger softer ones. A compost of equal parts of leaf soil and loam with a good sprinkling of sharp sand is excellent; then get some boxes, about 2 feet by 1 foot, and 3 inches deep, inside measurement, well drain and half fill with the compost. A box will be found to hold about fifty bulbs. Cover with more compost, just leaving the crowns clear of everything, and the bulbs firmly placed.

Take a corresponding box, and reverse it over the one just finished; fill another box, place on the top, with another reversed over, and so keep on till all are finished, as they then stand in one heap instead of occupying so much space, which is often needed for other things. They also keep themselves dark, but it is better to throw over them a cloth or mat. If done like this, the compost being moist, they will stand in any shed if not too dry, and will not require water. Growth soon commences, and when well on the move transfer them to good cool, airy, and light quarters, shading gently for a few days, also giving a copious watering. Such, in brief, is my method of procedure, and the majority produce three spikes of bloom, perfect in all respects. If they are required for succession, a little heat brings them into bloom in about ten days, while if necessary when the flowers are opening they can be potted, five bulbs in a 5-inch pot, taking care to pot evenly.

Dutch Hyacinths should be good, hard bulbs, potted into a thoroughly sound compost of equal parts of loam, leaf soil, and decomposed manure, with a little sand. Pot singly in clean 5-inch pots, with a little manure over the crocks. The crowns must be left exposed, and all must be put in a cold frame for two or three days. Then water them well twice over; two days after this get clean 4-inch pots, and reverse them over each bulb with a piece of slate or tile placed on the holes, fill in between with cocoa-nut fibre or leaf soil; keep the lights off in dry weather, except at nights.

When the growth is about an inch or more up the pieces of slate or tile should be taken away, for a few days first; then remove the pots, but choose a dull day if possible, or shade thinly, as if the pots are removed too soon the growth does not come nearly so strong. If any badly formed ones are found these should be forced, and the remainder well fed and naturally brought along, always being careful not to allow water to get into the flowers or growths. If the above system is carried out the grower may rest assured as to the results.—R. BASSIL, *Panybourne*.

CYCLAMEN PERSICUM.

I CONSIDER that the Cyclamen at fifteen months' growth ought to be at least 1 foot in diameter, having a dense mass of thick variegated leaves standing almost erect, and the flowers not more than 2 or 3 inches above the foliage. The flowers themselves should be broad in the petals, about 2 inches in length, nearly round at the ends, and having a slight regular twist in each segment of the corolla.

I will give a description of how I proceed from the commencement, as I generally prefer raising my own plants from seed. The seeds are sown in June, and put in an old Cucumber or Melon frame, with a temperature of about 65° or thereabouts. In six weeks the first leaf will be seen pushing itself through the soil; and when such is an inch in length the plants may be transplanted to a pan, still retained in the pit, and carefully shaded from hot sun with thin canvas, as a glaring sun I consider at all times highly detrimental to them, but especially when the plants are young. Towards the end of September I select a few of the strongest plants and put them in small pots, still retaining all in the frames close to the glass until the end of October, or even much later, according to the mildness of the season, as I find the young plants do better kept close in an old Melon frame, where a little heat still remains in the fermenting material. As soon as frost or cold weather sets in, all the Cyclamens are placed on a shelf in the conservatory, where the thermometer is not allowed to fall below 45°. Through the winter they do not grow much, but if the above temperature is maintained they will be found to have increased a little, which is all that is desirable. Those plants potted in autumn will require a shift into a size larger pot in April; those in the pans should be potted, and either retained in the conservatory, or, what is better, put in a frame with a little bottom heat for a month or six weeks, then about the end of May put out in a cold frame facing south-east, kept close for a few days, but eventually fully exposed during the daytime. When the plants are in this cool frame they should never be too much crowded, but allowed some few inches between the leaves, so that air may freely circulate, and prevent that drawn appearance which must at all times be carefully guarded against. The system I am advocating, it will readily be seen, is never to allow Cyclamens entire rest, but to always keep them growing, however slowly, and not, as is the custom with some growers I know, to let them partially die during the summer months.

In the management of old plants, if retained, I should adopt much the same system as with the young ones, except that they are not in spring introduced to a frame with bottom heat, but partially shaken out of their soil, potted lightly, not pressed too hard, then placed in a cool frame and kept close for a fortnight or three weeks. If the weather is hot during the months of June, July, August, and September, invariably sprinkle water overhead once in the forenoon, besides the usual watering on the soil; but it must be done with a watering pot having a fine rose, otherwise the foliage will be bent down by the weight of water, and eventually the leaves will not be erect and compact, which they ought to be. Another caution I must also give in reference to watering over the foliage, and that is never to close up the lights for the night until the plants are quite dry, otherwise you will have them tall, which, as I said before, must of all things be avoided. My plants are generally taken into the conservatory in full bloom early in October, when they continue to throw up flowers until the end of April, if not wished to seed from.

About Christmas a little liquid manure is weekly applied with undoubted advantage, and the bloom will be much prolonged by this timely stimulus. Should you wish the Cyclamen to flower for some months, it is of the greatest importance that all blossoms should be removed as soon as the tips of the reflexed limbs become tinted with brown. As soon, then, as the ends of petals become discoloured, they should be pulled out by giving a sharp snatch to the bloom, so as to detach it close to the corm; for if not entirely removed the remaining portion decays, and the decomposition spreads over the whole leaf as well as flower-stalks, and the plant will not completely recover that season, even if the evil be detected in its earlier stages. I mention this because occasionally, with extreme vigilance, it will occur in the most unsuspected way, and I would advise some of the blooms and leaves to be removed and the centre dusted over with sulphur, as the only means of saving the plant, which is sometimes of consequence if a well-known good variety.

The soil best suited to the Cyclamen in all stages is one composed of two-fifths coarse leaf mould, the same quantity of very light soft yellow loam, one-fifth dry cow manure, and sufficient fine white sand to prevent running together. The cow manure should be collected in fine weather, and it would be advisable, after rubbing small, to pour some nearly boiling water over it to kill all seeds, which are very troublesome if not destroyed in this way. The leaf mould should also be well wetted, and mixed with cow manure and sand; the loam should be ground down quite fine in a dry state, and mixed with the other ingredients, and you will then have the very best compost it is possible to make for growing the Cyclamen in.—S. H.

Notes & Gleanings

EVENTS OF THE WEEK.—Horticultural Londoners will find sufficient to interest them during the coming seven days. The National Dahlia Society will hold its annual show at the Crystal Palace on Friday and Saturday, September the 3rd and 4th. On Tuesday, besides the meeting of the Committees of the Royal Horticultural Society at the Drill Hall, the National Chrysanthemum Society will hold its first show for 1897 at the Royal Aquarium. On the 8th and 9th the exhibition of the Derby Agricultural and Horticultural Society will be held.

—— WEATHER IN LONDON.—Very heavy indeed have been the rains in London since last Wednesday. After our pages went to the machines on that day there were several drenching showers, while on Thursday evening there was a constant downpour from about five o'clock until nine, when it ceased until eleven, resuming again at that hour and continuing for some time. Friday was fine, and Saturday showery. On Sunday night the wind gathered strength, and rain fell heavily after eight o'clock. There was more rain on Monday, but the heaviest was during the afternoon of Tuesday, when we had quite a deluge, accompanied by thunder and lightning. Wednesday was very wet.

—— CRYSTAL PALACE FRUIT SHOW.—We would remind our readers that entries for the Show of British-Grown Fruit, which will be held at the Crystal Palace, under the auspices of the Royal Horticultural Society, on Thursday, Friday, and Saturday, September 30th, October 1st and 2nd, close on Saturday, September 25th. After this date none can be accepted. It is confidently anticipated that the exhibition will again be a magnificent one, and possibly superior to its predecessors. There are about twelve dozen classes in the schedule, so that no one should experience any difficulty in finding a suitable one. Schedules and all necessary information may be had from the Secretary, Royal Horticultural Society, 117, Victoria Street, Westminster, London.

—— DERBY SUMMER SHOW.—On Wednesday and Thursday, September 8th and 9th, the summer Show of the Derbyshire Agricultural and Horticultural Association will be held. There are considerably over 100 classes scheduled, of which some are open to all, others restricted to persons who do not employ a regular gardener, and the remainder to cottagers. In each of these sections the prizes are fairly good, the best, of course, going in the open classes. The one that should attract competition is that for a group on a space of 200 superficial feet, to include foliage and flowering plants. The prizes number five, of the respective values of £20, £15, £10, £5, and £4. A table of cut flowers has £21 allotted to it, and a decorative dessert table a similar amount. The sum of £6 is offered for three bunches of black Grapes, and also for three bunches of white Grapes. Special prizes are offered by Messrs. Sutton & Son, E. Webb & Son, and J. Carter & Co. for vegetables.

—— MR. G. W. CUMMINS.—We regret to learn that the above well-known competent all-round gardener has found it necessary to resign his position as head gardener to A. H. Smee, Esq., The Grange, Carshalton, after a term of sixteen years of successful service. Mr. Cummins says that since the great loss sustained by the lamented death of Mrs. Smee, who shared with her husband the delights afforded by their interesting garden, as well as by the death of Mrs. Cummins, "a gloom has apparently been hanging over the place," and he would, therefore, like to obtain an appointment in another district where opportunities are afforded for successful gardening. Apart from the unconventional picturesqueness of Mr. Smee's garden, with its Ferns and hardy plants, the most prominent features are the great collections of hardy fruit and Orchids. Though the garden is a semi-swamp Mr. Cummins has, by dint of thoroughly good work, won many of the silver-gilt and silver medals of the Royal Horticultural Society for collections of fruit, also several cultural commendations, first-class certificates, and medals for Orchids. He has also been awarded the certificate of the Surrey County Council for services rendered in educational work in domestic gardening. He speaks in the highest terms of Mr. Smee as an employer, and feels it an honour to have served him and his late estimable helpmeet so long. Mr. Cummins is in the prime of life—a quiet, persevering man, possessing a thorough knowledge of his business, and all who know him will be pleased to hear of his finding congenial occupation again.

—— ROYAL HORTICULTURAL SOCIETY.—The next meeting of this Society will be held on Tuesday, September 7th, in the Drill Hall, James' Street, Victoria Street, Westminster, from 1 to 5 P.M. A lecture on "Pitcher Plants" (Nepenthes), by Mr. Harry J. Veitch, F.L.S., will be delivered at three o'clock.

—— GARDENING APPOINTMENTS.—Mr. J. Dixon, gardener to Matthew Burnside, Esq., The Lindens, Helensburgh, has been appointed head gardener to J. R. Barlow, Esq., Greenthorne House, Edgworth, near Bolton. Mr. R. I. Inglis has been engaged by J. Stuart, Esq., to take charge of the gardens at Stonehurst, Ardingley. Mr. King has been appointed to succeed Mr. G. A. Bishop as head gardener at Wightwick Manor.

—— A CHARMING COMBINATION.—When walking through the Gardens of the Royal Horticultural Society a few days ago I was much struck with several of the beds that flank the main walk. The arrangements in all cases had been simple, and the results highly satisfactory. Of all, however, the bed that, in my opinion, looked the best was formed of the Silver Pelargonium Princess Alexandra and Ageratum mexicanum compactum The Zoo. All the plants had made splendid growth, and the rich blue of the Ageratum was grandly set off by the white and green leaves of the Pelargonium. I have seen beds of the same combination before, but never one to equal or even approach this for effect. —D. R.

—— WOLVERHAMPTON CHRYSANTHEMUM SOCIETY.—At a recent meeting the Chairman (Mr. G. A. Bishop) expressed his regret that, having resigned his position at Wightwick Manor, he would have to sever his connection with the Society, and vacate the position of chairman. Mr. Bishop spoke at some length upon various matters, and said in conclusion that it had given him great pleasure to have been associated with them as their Chairman in the past, and he wished them every success in the future. Mr. Richard Lowe testified to the loss the Society would sustain through the removal of Mr. Bishop from the district, and suggested as a mark of appreciation a suitable testimonial, this being seconded by Mr. J. E. Knight, and supported by several members.

—— SUTTON'S BEST OF ALL BEAN.—This remarkably fine Runner Bean is the only one now grown at Malshanger, as it so greatly excels all others. The rows of it I saw there the other day are 10 feet in height and perfect in growth and in fruiting from bottom to top. What a wonderful crop each row carried, and what beautiful straight, handsome, clean pods averaging 12 inches long! What a Bean would this be for market, and how the samples would sell as compared with the wretched ones gathered from pinched rows, the pods being short, generally much curved, and dirty, whilst the major portion are quite old and hard. The town consumer of Runner Beans never does taste such beautiful young straight tender samples as were those produced so abundantly at Malshanger.—A.

—— THE CHISWICK VINERY.—The great vinery in the gardens of the Royal Horticultural Society at Chiswick is now at its handsomest. The many Vines are all carrying good crops of fruit, and it is surprising to what size many of the bunches towards the top of the structure have attained. The fact that there is no sign of insect pests apparent on any of the leaves or wood is strong testimony to the careful attention the Vines have from Mr. Wright and his assistants. The house contains about thirty varieties, and affords an admirable place for close comparison between them, and as such is of material value to those not familiar even with the best known sorts. The weight of the whole of the bunches must be enormous, while the thinning of the berries was the work of weeks for half a dozen men.—VISITOR.

—— THE APPLE CROP.—Reports of the Apple crops have much improved from the big orcharding districts within the past few weeks. As the fruit increases in size so it shows up more plentifully on the trees, and owing to the dripping time the latter have held their fruit better than they did last year, when on account of the dryness of the season many Apples fell prematurely from the branches. Furthermore, there have not yet been any strong gales to disturb the immature crop, but the time of the equinoctials, which usually play such havoc, has not yet arrived. Early cooking Apples meet with good demand, and a better hand can generally be made by selling early—before the fruit is quite full grown—than later on, when markets are sure to be more or less glutted. Pears are selling very dear, and it would appear, says the "Rural World," that good early sorts, and late ones, too, for the matter of that, are not cultivated in this country as extensively as they might profitably be, seeing how suited our climate and soil are for producing the fruit.

—— EXHIBITING GRAPES.—Thanks are due to Mr. J. Hudson for showing how "big" bunches of exhibition Grapes were "made" for the recent Palace Show, also to "On-looker," for explaining to the readers of the *Journal of Horticulture* how it was done, and his comments thereon. But as an exhibitor I protest against that "ardent youth" having all the credit. Surely the exhibitor in question could not have been so blind as not to see what "his young man" had done when taking the "big" bunches from his box and staging them—which I saw him do—without noticing how "big" they had grown. I have at the present time 580 bunches of Grapes under my charge, but no "young man" would deceive me by adding shoulders or taking from them.—EXHIBITOR.

—— FIGS AT CHISWICK.—The magnificent collection of Figs in the R.H.S. Gardens is now about finishing its second crop of fruits. An examination of the several varieties here grown causes one to wonder why more are not cultivated in large establishments where the luscious fruits are appreciated. In most places one sees Brown Turkey or Negro Largo, or some other equally well-known variety, but rarely are the choicer flavoured ones in the collection under notice met with. Such as Bourjassotte Grise, Bourjassotte Noire, Nebian, Grosse Violette de Bordeaux, Monaco Bianco, and Pingo de Mel are perfect as regards flavour, while under Mr. Wright's experienced attention they give capital crops of fruit. I consider it is a pity that they are not more frequently seen.—WANDERER.

—— STRIPED FRENCH MARIGOLDS.—A very high class strain of these flowers is that grown by Messrs. Dobbie & Sons at Orpington. They plant several thousands, and resolutely save seed from the very best only, although I could, when recently looking over them, see little difference. Mr. Fyfe showed an interesting trial he was making of the effects of starving in one case by partially pulling a plant out of the ground and of feeding, another close by being occasionally dosed with liquid manure, which had made it very robust. So many blooms in each case will be saved, the seed sown, and planted out to mark results next year. As grown here, and a product of constant selection, the plants are less coarse growing than is usually the case. A distinct novelty has been produced this year, the petals being of a lemon ground instead of orange, and striping is seen in a marked degree. This will doubtless prove to be the progenitor of a new strain.—A. D.

—— EXETER SHOW.—The Devon and Exeter Horticultural Society held its summer exhibition on Friday, August 21st, on the lovely Northernhay. Had the weather been equal to the show many more visitors would have passed the gates. Special prizes were given by the Mayor of Exeter for the best ten dishes of fruit, and by the Rev. A. H. Cruwys for vegetables. In quality the show was the best for three or four years. The groups were better than anything of the sort previously seen in Exeter. Mr. W. Rowlands, gardener to Mr. W. Brock, J.P., of Exeter, took the premier prize of a silver cup, value £5, in each of the two classes arranged. The centre of each group was formed by a pleasing arrangement of cork, with plants judiciously disposed, while at the bottom there was a belt of bloom, which set off the whole very happily. Mr. G. Lock, gardener to Mr. Hill of Crediton, came second in each instance. Mr. Richards' group was also good. There were 109 classes and eighty-one exhibitors. The principal exhibitors were Mr. F. Bradshaw, Mr. G. A. Spottiswoode, the Hon. Lady Walrond, Sir Dudley-Duckworth-King, Mr. W. C. Cleave, Mr. Trehawke Kekewich, Sir John Shelley, Bart.; Mr. B. H. Hill, Mr. W. Brock, and Sir John Ferguson Davie.

—— ISLE OF WIGHT.—The Ventnor and Undercliffe Horticultural Society held its sixty-second show in the beautiful grounds of Ventnor Park on Wednesday, August 25th. Three marquees were well filled with fruits, flowers, vegetables, and plants. The quality of the former was especially good, whilst vegetables maintained their standard of excellence. The exhibit of Mr. W. W. Sheath, gardener to Miss Mitchell, Macrocarpa, Ventnor, consisting of large specimen Fuchsias, and Tuberous Begonias came in for much praise. Mr. A. Richards, gardener to J. Jessop, Esq., Cliffe Dene, Bonchureh, received the I.W. Horticultural Improvement Association's certificate for a collection of vegetables, which secured him the premier award in a special class for Messrs. Sutton's prizes. Amongst the other prizewinners were Messrs. G. Witty, F. Woods, F. A. Hoil, S. Cotton, F. Bastiani, J. and F. Niblett, W. Taylor, and W. Heath. The Secretary did excellent work, and deserves a word of praise for bringing one of the best shows ever held in the Undercliffe to a successful conclusion. The park in the evening was illuminated with fairy lamps and Chinese lanterns, which proved very attractive to the many visitors. Messrs. Peed & Son, Upper Norwood, staged fine blooms of Gloxinias, Tuberous Begonias, and leaves of Caladiums, which were greatly admired.—S. H.

—— ONIONS AT MALSHANGER.—It is an odd thing, but it is so, that hitherto most of the finest Onions grown or exhibited have been raised south of London. At Malshanger Park, Basingstoke, Mr. Kneller has Ailsa Craig in wonderfully fine form, grand bulbs, ranging from 2 lbs. to 3 lbs., and a big lot just a little lighter that should make, if planted, a superb seed stock. Seasons or soils seem to make little difference in the production of these splendid bulbs, raised from winter sown plants, a practice now so common. Whilst the Malshanger soil is light and rather close on chalk, that at Hackwood Park, but four miles away, is stiff loam on chalk, but at a considerable depth. Mr. Bowerman's bulbs are yet of the very finest, as was evidenced at Shrewsbury, where he had the best. Mr. Pope at Highclere and Mr. Lye at Sydmonton are both fine Onion growers.—D.

—— DAFFODILS.—Mr. Wm. Baylor Hartland sends us a copy of the Jubilee edition of his Daffodil album. If our verdant enthusiast will permit, we might almost describe it as the three P's—a combination of poetry, prose, and pictures. It covers what is described as the "starlit era"—1837-1897; but whether he regards the portraits of Watt, Stevenson, Edison, and Röntgen, or the sixty Daffodils that follow, as the bright particular stars, is not quite clear, so those who peruse the album must take their choice. Mr. Hartland says, "If we had such a copy in 1884 it would be worth £100." This reads almost like a confession by the producer that he has been for once a little behind the times, or he would have prepared something of the kind thirteen years ago. However, we happen to have had Mr. Burbidge's beautiful work. Miss Gertrude Hartland has represented the flowers with great clearness in the album, but if we might venture to suggest a correction in the nomenclature of Horsefield's fine variety, we should let it carry his full name, Horsefieldi, and not leave a letter out, as is so common in catalogues.

—— RUBBER PLANTS.—The investigation of rubber-yielding plants has resulted in drawing attention not only to new sources of supply, but in increasing the quantity available for commercial purposes. The remarkable rubber industry started in the Colony of Lagos in 1889 is described (*K.B.*, 1895, p. 241), and a figure is given of the plant, which hitherto had not been known as a source of commercial rubber. The Lagos rubber industry in two years developed into an export value of nearly £400,000. A somewhat similar industry had been started on the Gold Coast by the efforts of Sir Alfred Moloney, with exports in 1893 of the value of £218,162. Practically all the more important sources of commercial rubber are reviewed, while particulars respecting new rubber plants, such as Forsteronia graeilis in British Guiana, F. floribunda in Jamaica, and Sapium glandulosum in the United States of Columbia are also given. It may be added that information is desired at Kew respecting the plants yielding the Esmeralda rubber of Guiana (*K.B.*, 1892, 70) and that exported from Matto-grosso in Brazil. There is a doubt as to the distinction, if any, existing between caoutchoues yielded respectively by the Ule and Tuno trees of Central America. One of these is usually referred to Castilloa elastica, but botanical specimens are necessary of each tree to definitely decide the point.—("Kew Bulletin.")

—— MAIZE AS AN ENGLISH CROP.—Amongst the most useful, as well as valuable, of fodder plants, we may certainly class Maize. Business has recently taken us into Kent, and here on two large holdings we saw Maize growing most luxuriantly. Two, at any rate, of the principal farmers in the district we were in certainly are fully convinced of its value, for we saw not merely small plots but several acres being grown. The weight of its produce is stated to be about 30 to 40 tons per acre. The use it is put to is to provide food for milch cows and rams. Why, then, is so valuable a crop as this, producing in a very dry year such as the present a crop of grand succulent food, not more generally grown? Possibly because of the fact that it is looked upon as being a crop that is uncertain or doubtful, or, perhaps, from want of knowledge as to its great value. That it can be grown, and successfully grown too, is demonstrated not only by its success on the farms we saw, but in numerous other cases that one might quote. Then, again, the procedure of cultivation is very simple. It needs no particular preparation other than a good seed-bed and a fairly well manured piece of land. The great trouble its successful growers find is to keep the rooks from working at it when first sown or just coming up. Experience has, however, proved that if care is taken to properly bury the seed at a depth of 1½ to 3 inches, little or no trouble will arise from this source. Simple and easy then of production is this crop, which, were it more generally known, would soon, we are fully convinced, become not only one of the most popular, but one of the most valuable of all our fooder plants.—("Farmer and Stock-breeder.")

MEMENTOES OF SHREWSBURY.

On page 188 of our last issue we called attention to two medals that were being presented by Lord Kenyon, the President of the Shropshire Horticultural Society, to the two gardeners winning the largest amount in prizes—one in the open section, and the other confined to Shrewsbury. These were taken by Mr. J. McIndoe and Mr. C. Roberts respectively. Of this medal we are now enabled to give a photographic reproduction (fig. 30), showing both the obverse and the reverse. As no others will be cast from this die, which was designed by the Countess Feodore Gleichen, the medals will be the more highly valued by the recipients. On the page facing this appears a representation (fig. 31) of an epergne, two similar to which were purchased by horticultural friends, and presented to the Hon. Secretaries, Messrs. Adnitt and Naunton. These were very beautiful and elegant in design.

We are glad now to be able to state that rather over £160 was taken in the two days, more than has been taken on any previous show. Though rain fell heavily after 4 P.M. on Wednesday, the receipts were £25 above the previous best. The second day was fine on the whole, only slight showers falling, and these not sufficient to mar the proceedings. About 60,000 persons passed the turnstiles on the second day. By this it will be seen that the show was a record in more ways than one.

Fig. 30.—LORD KENYON'S MEDAL.

Shrewsbury Show Notes.

There was much to draw out the observatory powers of every visitor to the great show on the Quarry, Shrewsbury, much on the surface, but much more here, there, and everywhere not specially prominent, which was suggestive of consideration, as "A. D." has shown in his "Comments." If the observer were a thoughtful, ruminant sort of man, fond of noting little things, the side views, these inconspicuous things would be very likely to set him a thinking much more deeply than would those which stood out and compelled attention. Such is the opinion of the writer with respect to one function which, though the pencil of the reporter brought it to the notice of all in its salient features, was yet somewhat of a semi-private character; that was the luncheon where the officers of the Society, the deputation from the R.H.S., the Judges, and other invited guests were assembled.

It was an interesting and impressive scene, and a thorough gardeners' reunion. Let us look at it closely: it will bear it. Take first, as is right and fitting, the Chairman of the Society, the Right Hon. Lord Kenyon, who presided. A county nobleman, inheriting generations of courtly manners and gentle breeding, with a deep-seated love for all things connected with the county and neighbourhood and its people, he presided with easy grace and quiet dignity; not saying too much, but saying it well, he struck the key-note of the gathering in just the right words to make everyone feel at home and comfortable, and that, by the way, is the secret of a happy meeting. Then there was the genial, happy-faced, and pleasant-spoken Bishop of Shrewsbury, the Right Rev. Sir Lovelace Stamer, with Dean Hole, and the Rev. W. Wilks, the clerical Secretary of the R.H.S., representing the interest taken by the Church in horticultural matters. Then the courtly President of the R.H.S., Sir Trevor Lawrence, Bart., speaking with dignified eloquence on many things pertaining to horticulture, what it has done and what it can do, and of the Society he loves and cares for with such anxious care; and of this kindred Salopian Society which had so astonished him by its vigorous life and the glorious beauty of surroundings. And there was the deputation itself, notable in character and person, every member of which is an expert in some of the many phases of gardening.

The speech of the Dean of Rochester was admirable in every way, and characteristic of the man, both as a Dean and a gardener. It was full of wit and humour, "gay wisdom," and cheery optimism, with underlying tones of the higher things which concern all men. It sparkled with gems of thought as well as scintillations of wit and humour, and lifted gardening into that high position it ought to occupy in men's minds. The municipality of Shrewsbury was well represented by Lieut.-Col. Courcy Peele, with his patrician face and cheery speech, who most heartily and courteously welcomed the deputation from the R.H.S. and all other visitors to the town and the show. Then the Committee of the Society with its two efficient and ubiquitous Hon. Secretaries (Messrs. Adnitt and Naunton), composed as it is of every section of Shrewsbury people, from the town clerk, aldermen, councillors, magistrates downwards, all working unitedly and heartily to make the show a success. Then the Judges, representing every position in the horticultural world, from Mr. Owen Thomas, who presides over the gardens of the Queen; Mr. McKellar, who is head gardener to H.R.H. the Prince of Wales; Mr. S. T. Wright, the present Superintendent, and Mr. A. F. Barron, the late Superintendent, of the gardens of the R.H.S.; Mr. John Wright, the editor of "our Journal," down through ducal gardeners, trade gardeners, private gentlemen's gardeners, to the "spade and wheelbarrow" gardener, the writer of this note, and when they stood up together whilst Mr. Owen Thomas was returning thanks for them after the toast of "the Judges," the present writer thought they looked a very reliable, capable, practical body of men, most of them greybeards, having a life experience.

The ladies present must not be left out, as by their presence they lent an additional charm to the gathering; the Hon. Miss Kenyon (sister of the Chairman) and Mrs. Reynolds Hole (wife of the Dean of Rochester), with others, by their smiles and animated conversation most excellently supported the Chairman, and added a liveliness very acceptably recognised. One toast, and a very important one in the opinion of the present writer, was omitted, and that was the "Press." What would gardening and gardeners be or do without the gardening Press? the literature of which is excelled by none in the whole of the professions or trades of the country.

The great feature of the function was its happy, free-and-easy character, and its opportunity for chat with old friends; with intercourse with magnates in the gardening world by those who only knew them by names, but who found them pleasant, genial, chatty, ready to speak to any (even to the "spade and wheelbarrow" gardener), and to be spoken to. In this respect the time was all too short, but it will long remain a pleasant memory with one person at least, who also thought it deserved chronicling in the pages of the *Journal of Horticulture* by a special note.—An Old Provincial.

P.S.—The very interesting part of the proceedings at the luncheon of the presentation of two beautiful epergnes to the worthy Hon. Secretaries of the Shropshire Horticultural Society ought not to have been left to a P.S., but so it is. Of that presentation no more need be written than what Sir Trevor Lawrence so fitly said, that the recipients were so worthy to receive them that the gifts might have been more worthy to receive.—An O. P.

HARMFUL AND HARMLESS GARDEN MOTHS.—7.

A GOOD old gardener I once knew owned to feelings anything but friendly towards the entomological brotherhood. Though aware they killed and captured insects, he looked upon them as, in some sense, guardians or defenders of his enemies, and he had a special grievance. "They get over insects," said he, "from foreign parts. Of course they turn them out, if they have more than they want, in our gardens or fields, and very like they may breed here."

As a matter of fact, however, which is rather surprising, very few exotic insects have settled themselves in Britain, and I do not think entomologists are responsible for the introduction of any one. Still, I happen to be aware that several times, by way of experiment, companies of young gipsy caterpillars have been liberated to see whether they would be the parents of another brood, but either they died, or, if any moths emerged, their progeny perished. Yet the species stands on the list of British insects, formerly not uncommon, it is stated, though now rarely found wild here. Certainly there is no need to re-establish it, since we do not want it in our gardens or orchards. On the Continent this gipsy (Ochneria dispar) is still abundant and mischievous. I am afraid our friends in France and Germany are rather good-natured to the caterpillar, which, having a garb of red, grey, and black, also a large head, is fairly conspicuous at all ages; we probably would soon detect it on our fruit trees. Nor is the large moth hard to find during August, when it emerges, the eggs then laid hatch in spring. Presumably, the name of *gipsy* was suggested by the roving habits of the caterpillar.

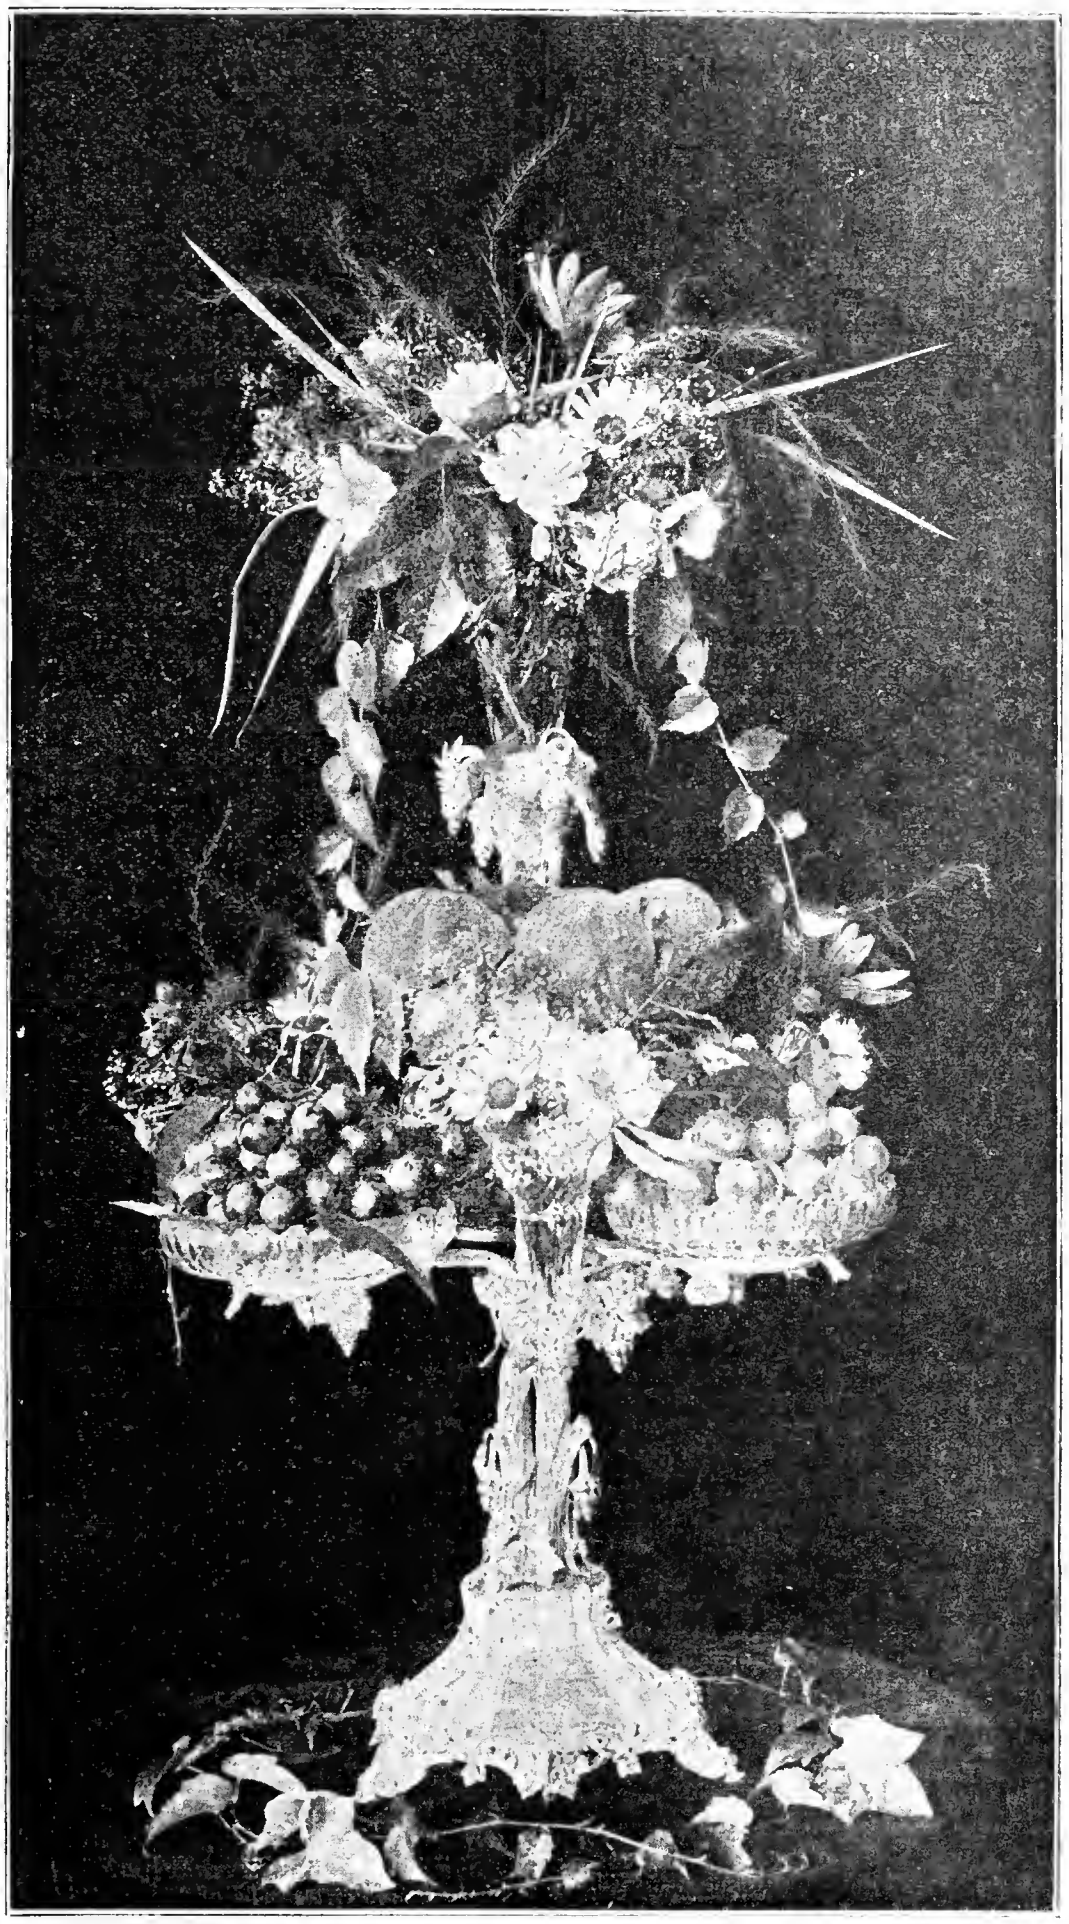

FIG. 31.—EPERGNE PRESENTED TO MESSRS. ADNITT AND NAUNTON.

The lackey moth (Bombyx neustria) is no stranger to us, at least in its caterpillar stage, when it is apt to be a persevering attendant upon the growth of some of our shrubs and trees. It can eat the foliage of many species, but we have to complain chiefly of the harm it does the Apple, especially when it has made a settlement in a large orchard. Both in orchards and gardens the moth secretes itself by day. Occasionally we disturb it from repose amongst grass or herbage in July or August after dark; the females are busy depositing their circlet of eggs round the twigs, which remain unhatched till spring. These should be removed or crushed whenever seen; they are regularly arranged in rows placed closely together, a batch of them numbering from 100 to 200, covered, too, with a glossy enamel, which protects them, and, as Mr. Wood thinks, suggested the name of "lacquer," or lackey moth, but here I consider he is wrong. It is reddish brown, with a faint bar across the fore wings. Some specimens are seen yellow, except the head and body, which are always red. But lackey probably alludes either to a habit of the caterpillar when young—that of going out and returning to the nest they make as a night shelter in parties, one slowly following another; or else, as Westwood remarked, it was given because the stripes on the insect resembled those which used to adorn the coats of footmen, but are now almost out of date.

The nests which are constructed by each colony, though small at first, are soon sufficiently apparent in the forks of branches, and the gardener can easily remove them with their tenants during a shower, or after sunset. Having passed the third moult they scatter about, and each caterpillar is independent; not unfrequently one of the high winds we sometimes have in June brings down numbers of them from the higher boughs. If we examine one it seems slender, and as if its skin was too loose. It is striped in several colours; on the dull blue head are a couple of black spots, which we might take for eyes, but such they are not, the eyes of caterpillars being undiscernible, as a rule. By an old French law, the owners of orchards were liable to a penalty if they had not by a fixed date in spring cut away all shoots containing webs of the lackey. A curious thing about the cocoon spun by this caterpillar is that with its silk and hairs there is mixed a quantity of yellow powder, in which the chrysalis is also enveloped.

Some years ago, a gardener at a house near Wimbledon Common showed me a specimen of the lappet moth he had captured in his grounds, and which he had preserved as a memento; it might have bred there, but more probably had flown over from the Common, where the caterpillar used to be found on Sloe, Willow, and other shrubs. It is a large, handsome moth, reddish brown and black; when at rest with folded wings it is not unlike a dried Oak leaf, so someone called it Gastropacha quercifolia. The caterpillar would also be somewhat of a surprise to a gardener if he came upon one of full growth, then quite 4 inches long, rather shaggy, specially remarkable for the singular lappets or flaps along the sides above the feet. It is generally noticed in early summer, the moth appearing about August. The new brood feed for a time in autumn before hybernating. On the continent, it is stated that the species is often injurious to young Peach, Plum, Pear, and Apple trees, the

insects being probably more plentiful than in Britain, where it is local or occasional, and not regarded as an enemy. Miss Ormerod's researches, however, brought out the fact that it might damage an Apple crop here, specimens of the lappet caterpillar being sent to her in May, 1893, from the nurseries at King's Acre, Hereford, belonging to Messrs. Cranston & Co. The grey variety had been taken upon a number of Apple shoots, which were stripped of all leaves, and even the ends eaten away.

Walking along a garden path one August day my attention was called by a friend to some delicate little moths that were sitting upon a Hawthorn hedge, and a few hours later they were disporting themselves over the path and beds—adjacent beds. This was the harmless species Cilix spinula, which reposes with the wings folded in roof-like fashion over the body, these wings being pure white crossed by a brown band, with also a double row of smoky spots on the margin. This is not all observable. In the centre of each fore wing is a cluster of silvery scales, which fancy compared to Chinese letters, and so the moth got the English name of "Chinese Character." We might find the caterpillars in June if we wanted them; small and singular they are, really worth examining. There is also a second brood in September I believe. Each has the body very much wrinkled and brown; the head has a two-cleft crown, and the two hind claspers are joined into a spike, which, when walking or eating, the caterpillar elevates in the air. Upon a twig we may come upon the compact gummy cocoon that encases the chrysalis.

No need is there, I should hope, to describe the buff-tip moth (Phalera bucephala), for every observant gardener has at various times seen it upon the trunk of a tree or reposing on a fence, taking advantage perhaps of a sheltered angle in a house, even occasionally settled on some low plant. By day the wings are wrapped about the body, giving it a cylindrical appearance, the tip, with its purple and silvery streaks on the grey, being conspicuous. It is a good-sized moth when the wings are expanded. The species is able to fly high and at a tolerable speed, the females depositing their eggs on many species of trees in and near gardens, often on Elm, Lime, and Hazel, these being placed in batches of thirty, forty, or more. We have had reported instances where the caterpillars have occurred on the Plum, clearing the higher twigs of their leaves. When the weather is gusty, buff-tip caterpillars are frequently blown off their food, and fall upon us as we walk under trees; or we see them in a path, hurrying to escape from a by-passer.

It is one of the few caterpillars that, apparently, attempts to bite if annoyed. While young they feed together in small parties as hatched, working on steadily with their heads close together, and their tails slightly raised, after the second moult they separate. At the beginning of August they are full grown, and display black and orange stripes on a yellow ground colour; the legs are deep black, head also, with a yellow triangle on the face. When undergoing the chrysalis change they simply lie on the earth, or just beneath, unprotected by any cocoon, and are therefore easily discovered and removed. To poultry these chrysalids are quite a dainty, and they hunt them eagerly if they have the chance.—ENTOMOLOGIST.

CALLAS.

SHAKING OUT AND REPOTTING.

WHEN the plants are wholly grown in pots annual attention is needed in the matter of supplying them with fresh soil. The readiest method is to turn out the plants and repot. In many cases the drainage will have become choked with soil probably washing in among the crocks. The latter should be picked out, and the old inert soil shaken away. Whether the crowns are potted singly, or two or more together, it is well to detach the young and weak suckers which surround them, leaving only the strongest, which are likely to throw up a spathe or spathes.

For single crowns 6, 7, or 8-inch pots are the most suitable. For larger pots clumps of several crowns may be selected, each crown a strong one. All weak growth among them ought to be pulled out, and as much of the old soil worked out as can be done without separating the clump. In some cases division may be an advantage, especially if the clumps are very large and have been long in one pot. Large pots may be made up with using single crowns if care is taken in spreading out the roots in the compost, not crowding them in one mass in the centre of pots.

In draining the pots it is best to carefully arrange a small quantity rather than introduce too much haphazard. Cover the crocks with a layer of flaky manure, and over this a slight dusting of soot, which will prevent the entry of worms, affording also a little food for the roots when they reach it in the course of growth. The roots ought not to be placed directly on the soot. A layer of soil must first be introduced.

The compost must be substantial loam, preferably of a turfy character, half decayed, and readily broken up. To four parts of this add one of decayed manure, with sand, charcoal, and a dash of soot, mixing all well together. Each bushel of compost may also have about 2 lbs. of some approved general fertiliser intermixed. Thomson's, Clay's, or Standen's are good. Pot moderately firm, especially working the soil in well among the roots when the latter have none adhering to them. Stand the pots in the shade for a few days, choosing a moist but hard base. Give a good watering immediately after the potting, so that those which have been the most disturbed will not droop seriously. Crowns which have not advanced far in growth will not flag at all..

When the roots begin to work freely in the compost the plants may have the benefit of the full sunshine. Attend regularly to watering, maintaining the soil in a healthfully moist state. In the earliest stages when the weather is dry and sunny, syringing daily will be advantageous. The plants are quite safe and better outdoors than under glass until frosts are imminent in October, when they had better be housed in a cool airy structure, and have abundance of light.—E. D. S.

BOWDEN HILL HOUSE.

FEW, if any, gardens in the West of England have made such rapid progress during the last three years as the above, the country residence of Herbert Harris, Esq. It is situated on a hill side, five miles from Chippenham, having some lovely views to the south and south-west, and commanding a most charming outlook as far as the eye can reach; it is well sheltered on the north and north-east by shrubs and woodland, intermixed with large and healthy specimens of Sequoia gigantea, Austrian Pines, and other Coniferæ. The pleasure grounds are not extensive, though many alterations are being carried out to improve them. The flower beds and borders are very bright indeed; the specimen Fuchsias which are plunged, and the Ivy-leaved "Geraniums" trained over arches, showing up to great advantage.

The gardens are about 200 yards distant from the house, through the newly planted orchard, which contains all the leading varieties of kitchen and dessert Apples. Between the rows of young trees, healthy crops of winter and spring vegetables look quite happy. Here, too, is to be seen a large batch of Czar Violets, with strong, dark, leathery foliage, which promise to render a good account of themselves, the maiden soil evidently being much to their liking. The new potting sheds, Mushroom house, fruit room, packing sheds, all of which have been erected under the supervision of Mr. Penton, are capital structures for their various uses. Near here are some well-arranged flower beds and borders, forming masses of brilliant colours. Chrysanthemums look promising; part of them are grown for large blooms, and others on the bush system. If hard, well-ripened wood is a good criterion, surely these will be in the ascendant during their flowering season. On entering the kitchen garden proper, the beauty of the border Carnations is worth going a long way to see, but as these have been previously noted in these columns, I will leave them, and say they are a grand lot, of which the energetic gardener may well feel proud.

The glass structures, some eighteen in number, consisting of vineries, Peach houses, Melon and Cucumber houses, ferneries, Orchid houses, with a good number of heated pits and frames, are all filled to overflowing with good produce. The early Vines were almost cleared of their fruit; the later ones were carrying good crops of under average quality, and not to the satisfaction of Mr. Penton. Endeavour is being made by root lifting and replanting to rectify the serious mistake committed by planting young Vines in too large and rich borders, thereby encouraging strong and succulent growth to the detriment of fruit-bearing qualities. The Peach trees are practically receiving the same treatment, gross growth difficult to ripen being too prevalent; Melons and Cucumbers showing full crops of good quality.

Orchids have made rapid strides during the last three years, both in quality and quantity, large numbers of imported and semi-established plants having been added to the collection. All are doing remarkably well, and will ere long form one of the largest collections in the West of England. In the Odontoglossum house are about 600 crispums and Pescatorei, mostly imported and doing well, as well as some Miltonia vexillaria. Hanging under the roof glass in the same house are Oncidium Rogersi, Dendrobium infundibulum, Masdevallia Roezli, M. bella, M. Backhouseana, and others. An intermediate house is filled with Cymbidium Lowianum, C. eburneum (which is a great favourite with Mrs. Harris), Sobralia leucoxantha, S. xantholeuca, S. Veitchi, and S. macrantha, with fine plants of Odontoglossum grande, O. citrosmum, and Cattleya citrina. Then there is practically a Dendrobium house, filled principally with good pieces of nobile, D. Schröderi, D. formosum giganteum, D. suavissimum, D. Brymerianum, D. chrysotoxum, D. Pierardi, D. Dalhouseanum; also a good batch of Oncidium ampliatum majus, and pans of seedling Orchids. Following is the Cattleya house, completely crammed with healthy inmates, including such varieties as C. Harrisi, C. labiata, C. Lawrenceana, C. gigas, C. aurea, C. Sanderiana, C. Warneri, C. Gaskelliana, C. Mendelli, C. Trianæ, C. Leopoldi guttata, also Vandas, Lælia anceps, L. a. Stella, L. a. Sanderiana, and many others.

The end house of this range is used for a fine-foliage plant stove, consisting chiefly of useful sized Crotons and Dracænas, splendidly coloured pieces. Arranged on shelves near the glass I noticed useful Calanthes, also a few plants of the Gold Fern (Gymnogramma) which are much cherished for their splendid colour and dense habit. In the fernery we meet with some very fine specimens. Adiantums trapeziforme, Lawsonianum, concinnum, farleyense, cardiochlæna, and cuneatum, with Goniophlebium appendiculatum, all really good specimens, and some other varieties that would soon be equally as good had they more room to develop themselves. A house adjoining the fernery is at present used for decorative flowering plants, such as Lilies, Tuberoses, and Begonias, and is used later for winter flowering Carnations, of which I noticed

numbers plunged in their summer quarters, Carnations, Roses, and Violets being especial favourites with Mr. and Mrs. Harris.

The conservatory is a very prettily arranged building, quite out of the ordinary type. The inside walls are so arranged as to form miniature rocks planted with various Ferns, Begonias of the Rex varieties, small waterfalls trickling down, and fountains playing in the shady nooks having a very cool, refreshing appearance. In the centre of the building is a very fine Tree Fern, around which is arranged a circular group of choice flowering plants. Quantities of plants and cut flowers are required for the decoration of the mansion.

In the kitchen gardens the crops show little signs of the drought; the vigorous growth at once clearly demonstrates that no mere "tickling" of the surface is allowed, but deep tilth and good feeding, cleanliness, and doing the work at the proper time are the most certain roads to "success." Strawberry culture, both forcing and outside, is well carried out at Bowden, Royal Sovereign being the favourite variety, though many others are cultivated successfully. Mr. Penton has a high opinion of Leader, and predicts for it a prominent position. Lettuce Sutton's Mammoth Cos and Summer Favourite were conspicuous with immense crisp heads. The whole surroundings reflect the highest credit on all concerned in the maintenance and management of this garden.—J. F.

STAG'S-HORN FERNS.

THE Ferns popularly known by the above name belong to the genus Platycerium (literally Broad Horn). They form a natural group of plants, and were originally united with Acrostichum; but to my mind they have nothing in common with the species which represents that genus in our ferneries.

Platyceriums are characterised by their large sterile fronds, which are entirely different in shape from the fertile ones; they are sessile, and grow erect and flat, overlapping each other as they increase in numbers and in size. The fertile fronds are stalked, standing out erectly or horizontally from the barren fronds (or shields, as they are not inaptly called in a popular way); they rise from the little depression at the base of the sterile fronds, and are many times dichotomously forked, having more or less broad and obtuse segments, which are thick and leathery in texture, and clothed with a dense covering of peculiar stellate scales, which give the young fronds the appearance of having been dusted over with a white powder; the veins are somewhat indistinct, but are coarsely anastomosed, whilst the receptacle is irregular, but usually occupies he greater portion of the apices of the under side of the segments.

Platyceriums grow naturally upon the trunks and branches of forest trees, and are most successfully grown under cultivation when treated as epiphytes, and placed upon blocks of wood or in baskets. I have grown them in pots; but I do not recommend that system, because the peculiar habit and beauty of the plants cannot be developed under such treatment, even in cases where pots are made specially for them.

In providing blocks of wood for these plants the operator must not go to work with a narrow mind, for although the plant may not now have shields or barren fronds more than a few inches in diameter, it will, if properly treated, soon produce others, which may probably attain some 12 inches or more in breadth, and if a block sufficiently large is not provided the shields will clasp round it instead of being kept spread open, as they would be if upon a broad block, and thus in the case of the small block half the beauty of the plant is lost. This is a point too often overlooked, and therefore I would specially draw their attention to it.

Having selected a block of wood of sufficient dimensions, first fasten the plant upon it with some fine copper wire, and then take some living sphagnum moss and rough peat from which all the fine earthy particles have been beaten out, and pack down behind the barren fronds so as to make the plant quite firm; give it a good soaking in a tub or pan of water, and nothing more remains to be done but hang it up in the desired position, and keep it abundantly supplied with water from the syringe. Care must be taken to prevent the lodgment of either thrips or scale, for if either be suffered to gain a footing they will speedily turn the fronds from their lovely green colour to a nasty, dirty, rusty brown, which will present quite the reverse of the effect desired; therefore examine them occasionally, and promptly remove any of these pests should they put in an appearance. I do not recommend the sponging of the fronds if it is possible to avoid it, as by this means the covering of stellate scales is removed, and thus, to my mind, the plant becomes disfigured.

There are but few species of Platyceriums known to science, and nearly all of them have been introduced to cultivation; but perhaps there are more species or varieties yet to come which will lend an additional charm to our ferneries. This much can be said of those we have, they are all so entirely distinct that a block or bracket may be found for each in even a small Fern house, without producing a sameness or monotonous appearance, whilst their habit is so peculiar and extraordinary that no Fern house should be without them.

P. alcicorne.—I before mentioned baskets as being suitable for the growth of Platyceriums, but this is the only one to which that style of culture is applicable. The shields or barren fronds are small, and as it throws up innumerable young plants from its roots, in the course of a few years it forms a large globular mass, producing fertile fronds from all parts of its surface. It is not the most beautiful of the genus, but is specially deserving the attention of those having only a greenhouse fernery, as it succeeds admirably under cool treatment; moreover, in a young state, and for several years, it may be grown with advantage by those who have only a Fern case to indulge their taste. In such a position the half of a cocoa-nut shell forms a capital basket, and when suspended from the roof of the Fern case does not present an unsightly appearance. This species is widely distributed through the islands of the Indian Archipelago, and is also common in Australia.

P. alcicorne majus.—As its name implies, this is a large form of the original type, and as such it is well deserving the attention of Fern growers. Although it may be grown in a basket, the large size of its barren shields and the more forked character of its fertile fronds induced me to give preference to a large block of wood. It has been introduced from Australia.

P. biforme.—This species is a native of Burmah and various localities in the Indian Archipelago, and must be treated to stove temperature. The sterile fronds are somewhat broad, whilst the fertile ones are long and pendulous. The sori in this species are not produced near the apex of the segments, but upon a scutiform lobe near the first divisions of the fronds. It is a most beautiful species.

P. Stemmaria, known also in collections by the name of P. æthiopicum, is a very distinct plant, but is not such a general favourite, because the barren shields die and turn brown every season. This, however, should not deter or discourage the amateur from finding a place for it in the fernery, as each year's growth completely covers the old ones. The shields are large, and densely clothed with stellate scales, which give them a what glaucous aspect. The fertile fronds are broad and short, several times forked, and very leathery in texture. Native of Western Africa.

P. grande.—This species must be provided with a large and broad block of wood, or half its beauty is lost. The sterile fronds are erect, the upper edge variously forked, but plain and rounded below. Fertile fronds from 1 to 3 feet in length, coriaceous in texture, dichotomously forked, and light green in colour. Too much cannot be said in praise of this charming plant. It must be grown in the stove fernery. Native of Australia and the Malay Archipelago.—C. E.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE Committee, Treasurer, and Trustees, acting on behalf of the members and subscribers of the above Institution, with the concurrence of its President, the Duke of Westminster, recently forwarded through the Home Secretary a loyal and dutiful address to the Queen, for forty-six years the Gracious Patroness of the Charity, congratulating her Majesty on the completion of the sixtieth year of her beneficent reign, and the following reply has been received from the Right Hon. Sir Matthew White Ridley, M.P., by the Secretary:—

Secretary of State, Home Department,
Whitehall, S.W., August 24th, 1897.

SIR,—I have had the honour to lay before the Queen the loyal and dutiful address of the Gardeners' Royal Benevolent Institution, congratulating her Majesty on the completion of the sixtieth year of her reign, and I have to inform you that her Majesty was pleased to receive the same very graciously. With reference to the application for permission to make use of the words "Victorian Era" in connection with the title of a fund now being raised by the Institution, I have to acquaint you that her Majesty graciously approves of the desired permission being granted.—I am, Sir, your obedient servant,

(Signed) M. W. RIDLEY.

KENT CHAMPIONSHIP BELT COMPETITION.

THE Kent belt competition instituted by Mr. Cannell, of Swanley has done an immense amount of good for horticulture in the county. A few years ago it would have been deemed an impossibility for vegetables to be grown to their present quality. So successful has the competition in vegetables become that fruit and flowers are now introduced, and these new features have added to the beauty of the competition. The struggle for possession of the county championship this year took place at the annual exhibition of the Rodmersham Amateur and Cottage Gardeners' Association, which was held in a large booth in Rodmersham Park on Wednesday and Thursday, August 25th and 26th. It was here that the competition for the Kent championship belt took place two years ago, after the honour had been won by Rodmersham from Milton in the previous year. Two years since the Miltonians came to Rodmersham, and wrested the championship from their neighbours. Last year the fight took place at Milton, and here Rodmersham once more turned the tables on the Miltonians, and for the past twelve months the coveted belt has found a resting-place at Rodmersham. Now the contest for the title of the champions of Kent has again taken place at Rodmersham, and, by a singular coincidence, the championship has gone to Milton for the third time. Meanwhile, other societies in the county do their best to stop this "little game," as it has been not inaptly termed, but so far they have been powerless to prevent it. There were eleven entries for the competition this year—viz., Eynsford, Strood, Ash, Penshurst, Charing, Ightham, Milton, Linton, Milsted, Westgate, and Rodmersham (the holders). At the last minute Charing, Ightham, and Eynsford withdrew, leaving eight stern and determined competitors to enter the lists. The prizes went to Milton first, Rodmersham second, and Penshurst third. The competition is open to all amateur and cottage garden associations in Kent.

ROSES

Own-root Roses and the Mangold Heap.

Poor Mr. Raillem has been so signally worsted in the Medea *versus* Maréchal Niel controversy that it is a pleasure to be able to afford him a feeble flutter (and it is a feeble one) at my expense over own-root Roses. It is quaint, though, and the more humorous since the author seems to be so sublimely unconscious of it, to note the comparison between his eighth paragraph and his first. Truly we are advancing in the knowledge of how to beautify our flower gardens when we are taught to turn our Rose beds into Mangold heaps! Consider the exquisite grace of a series of such mounds. The suggestion gives us new conceptions of garden decoration. Once put on the track by Mr. Raillem, we can evolve many new and striking ornaments. Amongst others I might suggest turning our Roses upside down, decorating them with an old coat and a battered hat, and making them serve as scarecrows. They would then be not only beautiful (as beautiful as the Mangold heaps any way) but useful. I venture to recommend this as a hardy perennial worthy of attention. It will not exactly crop up fresh every year, but by changing the hat occasionally we shall get some choice effects.—W. Pea.

SHRUBBY VERONICAS.

Our indebtedness to New Zealand and Tasmania for the many new and rare additions to our already large collections of garden plants can hardly be over-estimated when the surprising way in which some of them adapt themselves to our average English winter is taken into consideration. That much remains yet to be done in the way of fresh introductions before we can form an adequate idea of the richness of the vegetation in those countries is shown in the words of a popular writer, who, in reference to Tasmania in particular, says, "Somersetshire cannot surpass her orchards, nor Devon match her flowers;" and even in the handbooks of the floras the many plants we see described as exquisite garden plants that have not yet been introduced lead us to hope for not a few genuine surprises, and anxiously await the result of some enthusiastic and enterprising collector's researches.

Of the New Zealand plants already introduced shrubby Veronicas form a fair proportion, and are useful in many ways, among which the decoration of the rockery and to give variety to the mixed flower border are not the least prominent, some few also being specially adapted for pot culture, and when well grown they are by no means to be despised either as window or table plants or for the greenhouse. Their cultivation is comparatively easy, the principal object being to obtain well furnished plants, which is by no means difficult, as they will stand any amount of pinching back without injury, and may be left to the discretion of the grower.

I have found stopping the shoots early in spring the most successful way of obtaining dwarf bushy plants, and it does not in the least retard their free flowering. It is always advisable to keep them in rather small pots, giving a top-dressing of stable or liquid manure in small quantities to compensate for the restriction.

Traversi, hardy except in very severe winters, is free flowering and of neat habit. It seldom grows more than a foot to 2 feet in height, and its large spikes of white and purplish flowers, somewhat in the way of the well-known Andersoni, are very attractive; they are produced in the greatest profusion, and last more or less throughout the summer. The leaves are of a lively shining green, and for this reason the plant is extensively used in some large gardens for greenhouse decoration, together with many other fine-foliage plants to intermix with spring flowers. It is increased from cuttings with the greatest ease in the ordinary way. A native of the Middle Island, where it is found abundantly.

Salicifolia is one of the most variable of all the Veronicas, and under cultivation runs into many forms. It is one of the principal parents of the many hybrids which we have in gardens, among the best of which are kermesina, Lindleyana, Andersoni, versicolor, linearifolia, and many others, the merits of which are pretty well known and appreciated. The flowers are produced in the same way as the above, and are variable both in size and colour. This is a desirable plant for the conservatory, and very useful for planting between Camellias in beds.

Of hardy species we have a large number to choose from, and no one who has them nestling among the stones in the rockery can doubt their usefulness or appropriateness for this purpose. Indeed, it would be difficult to find another class of plants more suitable, and possessing the twofold quality of enlivening with their flowers, which, if not very attractive, are interesting through the summer, and of breaking the monotony of bare stones and rocks with their shining green or glaucous leaves during winter.

In favourable situations elliptica (syn., decussata) attains considerable dimensions in the course of two or three years, on account of which it should be planted in bold positions with good backing. It has been confounded with formosa, but how I am unable to determine, the latter being a small-leaved species from Tasmania, while elliptica has large, broad, oval shaped leaves, and is very distinct. The flowers, which are produced in clusters, are white or purplish, becoming more intense as they grow older. The figure shows a small flowering branch of this plant.

Diosmæfolia is a dwarf bushy species, seldom attaining more than 1 foot in height. It has been appropriately named "The Rockery Gem," the numerous flowers covering the plant. Among others equally desirable are lævis, amplexicaulis, anomala, chathamica, epacridea, Haasti, pinquifolia, salicornioides, and ligustrifolia.—M. S.

HORTICULTURAL SHOWS.

PERTH.—August 20th and 21st.

The annual exhibition of the Royal Horticultural Society of Perthshire was held in the City Hall, Perth, on Friday and Saturday, 20th and 21st August. Owing to many local shows being held on the same date the entries were considerably under the average, but the merits of the exhibits were in most cases quite up to the usual high standard.

The main feature of the show was the groups of plants 9 feet in diameter, open to all; and the tables of plants, 10 feet by 5 feet, open to gardeners. In the former there were three entries. The premier position was gained by Mr. E. Rogers Bush (of Messrs. Harley & Sons, florists) with a gracefully arranged group, having a nice Phœnix as a central plant, surrounded with Crotons, Pandanus, Cocos, Eulalias, and Cyperus distans, intermixed with Carnations, Chrysanthemums, and Gloxinias, nicely set in a groundwork of Maidenhair Ferns and Coleus. The second prize was gained by Mr. Wm. Little, gardener to P. W. Campbell, Esq., Muirtonbank, with a somewhat similar arrangement; and the third by Mr. Leslie, gardener to Andrew Coates, Esq., Pitcullen, whose group contained some excellent Crotons, Cocos, and Cockscombs.

There were four entries for the tables, all of which were of very high merit. The first place was adjudicated to Mr. F. Nicol, gardener to Thomas Roy, Esq., of Craigclowan, for a table principally composed of Orchids, Liliums, and Adiantums. Amongst the Orchids were some nice Odontoglots, Dendrobes, Cypripediums, Oncidiums, and Cattleyas, all combining to make an exceedingly pretty table. Second, Mr. Wm. Little, who had splendidly coloured Crotons, Dracænas, Pandanus, interspersed with Pancratiums, Liliums, and Clerodendron fallax, gracefully set up in a background of Ferns, and edged with Panicum, Selaginella, and Asparagus deflexus. Third, Mr. Leslie; fourth, Mr. T. Dobbin, gardener to James Ramsay, Esq., Balhousie Castle, whose table contained some handsome little Crotons. Specimen plants were not numerous, the leading positions were gained by Messrs. Leslie and Little.

Fruit, considering the season, was fairly good. For collections of twelve and eight sorts Mr. Leslie was the only competitor, showing very good fruit in both collections. Grapes were very good. For two bunches Black Hamburghs Mr. Lawrence, Oakbank, was first with beautifully finished medium sized bunches; Mr. Dobbin second. For two bunches Muscat Mr. Leslie occupied first place. One bunch black, any sort, Mr. Little first with Gros Colman; second, Mr. Leslie with Madresfield Court. Hardy fruit was largely shown and of fairly good quality.

Cut flowers were shown in the various sections and helped to brighten the hall. Messrs. D. & W. Croll staged excellent Roses, both H.P. and Teas. For Chrysanthemums, twelve blooms, ladies' sprays and buttonhole bouquets, Mr. Bush occupied first place; twelve greenhouse and stove trusses, Mr. Little was first with an excellent stand; while in the class for bouquets Mr. Harris, Greenbank, was winner.

Vegetables were of the usual excellent quality, the principal prize-takers being Messrs. Harper, Tulliebelton; McFarlane, Kilgraston; and Robertson, Springland. In the amateurs' section there was a considerable falling off, owing to the numerous local shows being held at the same time.

BRIGHTON.—August 24th and 25th.

Good as the exhibitions at Brighton have been of late years the last summer show was in advance of its predecessors. Groups, both of Ferns and miscellaneous plants were good, while the stove and greenhouse plants from Mr. J. Warren, Hand Cross Park, Crawley, were remarkable for their rich colouring and general excellence. The Dome, Corn Exchange, and Western Lawn proved none too large for the exhibits.

Mr. W. C. Hollands, Tunbridge Wells, won for a circular group, 18 feet by 10, with a light and graceful arrangement. This secured the Society's silver medal and possession of the Corporation challenge cup for the year, in addition to a substantial prize. Mr. G. Miles, Dyke Road, Brighton, was a good second, but appeared too heavy in the background.

This exhibitor's group of Ferns was one of the prettiest features in the show, although closely run by Mr. Adams, gardener to the Rev. Sir George Shiffner, Bart., Coombe Place, Lewes, who always has Ferns in grand style. Tables of flowering and foliage plants were good, Mr. Lawrence, gardener to Mr. T. Oliver, Horsham, just beating Mr. W. C. Hollands.

For six stove and greenhouse plants in bloom Mr. A. Gibson, gardener to Mr. T. F. Burnaby Atkins, Halstead Place, Sevenoaks, beat Mr. J. Warren, Hand Cross Park, but Mr. Warren was ahead for six exotic Ferns, a specimen Croton, a specimen Palm, and a stove or greenhouse plant in bloom. Mr. T. Fairs, gardener to R. Clowes, Esq., Clayton, Hassocks, was first for twelve Begonias, Mr. E. Meachen, gardener to Miss Armstrong, Woodslea, Preston, being a good second. Mr. E. Boyling, gardener to Miss Willett, Hurstpierpoint, went before Mr. Fairs for six Gloxinias. Mr. Lawrence beat Mr. H. Garnett for six well-coloured Crotons, but the positions were reversed for the same number of

Dracænas. For six British Ferns Mr. G. Miles, Dyke Road Nursery, won from Mr. F. Collis and Mr. J. Lewis, Preston Road. The twelve table plants were good, Mr. Lawrence, Messrs. W. Miles & Co., Hove, and Mr. J. Warren, Hand Cross Park, taking honours as placed. For a small collection of Orchids Mr. J. Harper, gardener to E. A. Tucker, Esq., Vernon Lodge, Preston, was ahead of Mr. H. Garnett, gardener to R. G. Fletcher, Esq., Mount Harry, Preston, Mr. F. Collis following.

For twenty-four varieties of stove and greenhouse cut flowers the silver medal and first prize were awarded to Mr. W. Archer, gardener to Miss Gibson, Saffron Walden, Essex. There were only two competitors in the class for twenty-four Roses, Mr. W. Taylor, Hampton, Middlesex, and Mr. T. Durrant Young, Eastbourne, being close together, but placed as named. Mr. Harris, gardener to Mrs. Eversfield, Denne Park, Horsham, was well ahead of Mr. Young for twelve Teas or Noisettes. One of the most attractive features of the show was the Dahlias. These were exceptionally bright and good, and we can do no more than say the arrangement of Cactus and Pompons left nothing to be desired. Mr. T. Mortimer was ahead of Mr. F. W. Seale, Sevenoaks, for forty-eight Show or Fancy varieties. Mr. Seale beat Messrs. Keynes & Co., Salisbury, for twenty-four varieties of singles, and also for twelve Pompons. Messrs. Keynes & Co. were well ahead for twelve bunches of Cactus varieties, making a grand show. Hardy perennials and annuals were good and numerous. Floral designs were more numerous and varied than was the case last year, and all were good. Mr. J. Charlton, Tunbridge Wells, was first for a ball-room bouquet, and also for a wreath device of flowers, being closely followed by Mr. F. W. Seale in the latter class. Mr. Seale was first in a strong class for a centrepiece suitable for the dinner table.

Mr. J. Gore, Polegate, staged a grand collection of fruit, and won from Mr. G. Goldsmith, gardener to Sir E. G. Loder, Bart., Leonardslee, Horsham, in what was a strongly contested class. Grapes were good. Mr. T. Davey, gardener to E. J. Pope, Esq., Horsham, was first for three bunches of well finished Black Hamburgh, Mr. T. Osman, gardener to L. J. Baker, Esq., Chertsey, following. For three bunches of black and three of white Grapes, Mr. D. Gibson won, Mr. Osman again taking second place. Mr. Harris, Denne Park, was first for one bunch in the amateurs' division. Mr. Lawrence, gardener to T. Olivier, Esq., Horsham, won for two distinct Melons ; and Mr. R. H. Knight, gardener to Mrs. Bannister, Cuckfield, for one Melon. Peaches were good and highly coloured, Mr. F. Potter, gardener to R. Worsley, Esq., Cuckfield, winning for two dishes, and Mr. J. Allen, gardener to G. H. Field, Esq., Ashurst Park, Tunbridge Wells, for a single disb. Other fruit was exceptionally good for the season.

The bronze medal and first prize for a collection of nine vegetables were strongly contested, as was that for six dishes of Potatoes. Mr. W. Manton, gardener to Mrs. Clifford Borrer, Pickwell, Bolney, and Mr. F. Draycott, gardener to Lieut.-Col. Dudley Sampson, Lindfield, were first in these classes. A special prize for a collection of six distinct vegetables, gentlemen's gardeners only, was won by Mr. H. Knight, gardener to Mrs. Bannister, Cuckfield.

Non-competitive exhibits need some little mention. Lilies, bulbs, and various decorative plants came from Messrs. W. Balchin & Sons, Hove and Hassocks ; Messrs. Veitch & Sons, sent new and rare plants ; Messrs. Peed & Sons, well coloured Caladiums ; and Messrs. J. Laing and Sons, Begonias. Each gained the Society's silver medal.

KINGSWOOD AND WEST GLOUCESTERSHIRE.—AUGUST 25TH.

THIS comparatively young society has made such rapid strides that it bids fair to soon become the most popular in the West of England. Upwards of £220 is offered in prizes, these including three handsome silver cups, and competitors were attracted in large numbers from far and near. Four large tents were filled with the various exhibits, the quality of which was remarkably good throughout. Last year the date of exhibition was a most unfortunate one, and a serious loss had to be chronicled. This time they were favoured with delightfully fine weather, and the consequence of this and the good reputation of the society was a "record gate," or upwards of 10,000 visitors. Messrs. Jullion and Cottle once more proved themselves to be capable honorary secretaries.

In the premier class for a collection of stove and greenhouse plants Mr. J. Cypher, Cheltenham, was well first, having fine plants of Kentias, Crotons, Bougainvilleas, Ericas, and the like. Mr. W. Vause, Leamington, was second, and Messrs. T. B. Woods & Son, Chipping Sodbury, third. The first prize for six Ferns was easily won by Mr. W. Rye, gardener to Captain Bellfield, Frenchay, whose best plants were Todea pellucida, T. superba, Davallia elegans, and D. fijiensis. Mr. F. W. Lockwood was second. Fuchsias were good. Mr. G. Tucker, Trowbridge, was first for six varieties, showing huge pyramids, not, however, so fresh and freely flowered as the second prize plants shown by Mr. W. J. Mould, Bath. Zonal Pelargoniums made a fine display. First, Mr. W. J. Mould ; Messrs. J. B. Woods & Sons were second. Tuberous Begonias, both single and double flowered, were numerous and good. Messrs. J. Rogers, W. Rogers, and T. J. Farr were the most successful with these. Mr. D. Jefferies had the first prize for Petunias ; second, Mr. F. Baynton, gardener to P. Fussell, Esq., Kingswood, both showing excellently.

There were five competitors in the class for a group of plants arranged for effect on a space not less than 100 square feet. Mr. J. Cypher was first for a light and effective arrangement, in which choice Orchids were conspicuous. Mr. T. Wilkins, gardener to Lady Guest, Henstridge, was second, Mr. W. Vause third, and Messrs. E. S. Cole and Son fourth, all acquitting themselves in good style.

Amateurs' plants showed marked improvement on previous years. With six stove and greenhouse plants in flower there were five competitors, all staging most creditably. The first prize, a silver cup value 5 guineas, went to Mr. G. Tucker, who staged grandly flowered plants of Lapageria alba, Dipladenia Brearleyana, Bougainvillea Sandersi, Ixora Morsei, Stephanotis floribunda, and Erica McNabiana. Mr. T. Wilkins followed closely with large specimens, his best being a fine Bougainvillea and Stephanotis floribunda. The third prize went to Mr. W. Rye. The silver cup for six fine-foliaged plants was well won by Mr. T. Wilkins, who had fine healthy specimens of Cycas circinalis, Kentia Canterburyana, K. Belmoreana, Dasylirion longifolium, and large richly coloured Crotons Williamsi and interruptum. Mr. Rye was second, and Mr. E. Towill, gardener to Mrs. Gale Coles, third. Mr. Wilkins also succeeded in

FIG. 32.—VERONICA ELLIPTICA.

winning the first prize for six exotic Ferns, Mr. W. Rye again being second. Zonal Pelargoniums were well shown by Messrs. E. Towill and S. Bryant, gardener to Dr. Grace, Kingswood ; Coleus by Messrs. S. Bryant and J. Bainton, gardener to D. Jefferies, Esq.; Begonias by Messrs. Cornish and J. Rogers ; and Gloxinias by Messrs. E. Sheppard and W. Towill, who were respectively first and second in each instance.

Dahlias as usual were well represented, several leading growers competing. The best twenty-four were shown by the veteran exhibitor Mr. T. Hobbs, Bristol ; equal seconds, Mr. G. Humphries, Chippenham, and Mr. J. Walker, Thame. For Fancy Dahlias Mr. Humphries was first, and Mr. T. Hobbs second. The best singles were shown by Mr. J. Burgess ; second, Mr. G. T. Bryant, while for Cactus-flowered varieties Mr. G. Humphries was first, and Mr. J. Burgess second. Mr. S. Tresider, Cardiff, was easily first for twenty-four varieties of Roses, three blooms of each ; second, Mr. G. Garraway, Bath. Mr. T. Hobbs was first for twelve varieties. Asters were good, and with these the most successful were Messrs. T. Evry, C. H. Vicary, and F. Hooper. Hollyhocks were particularly good ; Mr. W. Smith, Kingswood,

was first, and Mr. F. Burgess second. Tuberous Begonias were well shown by Messrs. J. B. Blackmore, J. Cornish, and J. Rogers. Hardy herbaceous flowers in bunches were quite a feature. With these Mr. W. Smith was first, and Mr. G. Garraway second. Mr. J. Cypher was first for stove and greenhouse flowers, and Mr. A. T. Robinson second. Sprays, buttonhole bouquets, memorial wreaths, and vases were all numerous and good.

Asters in the amateurs' classes were particularly good, and with these the prizewinners were Messrs. Isaac and J. Burgess. Mr. Towill was first, and Mr. E. Shepherd second, for hardy herbaceous flowers in a well filled class. Mr. W. Rye staged the best bunches of choice flowers, Mr. Towill taking the second prize. Mr. T. Hobbs gained all three first prizes for Roses, Mr. J. Newman also showing well. Hollyhocks appear to be more popular about Kingswood than in most other districts. With these Mr. J. Burgess was first, and Mr. S. Bright second. Mr. J. Newman was first, and Mr. T. Hobbs second for double Dahlias, and Mr. J. Burgess first, and Mr. S. Bright second, for single varieties in well contested classes. Mr. F. J. Tarr was first, and Mr. J. Burgess second, for Zonal Pelargoniums.

There was a slight falling off observable in the quality and quantity of the Grapes shown, but all the other fruit classes were better filled than might reasonably have been anticipated. The silver cup offered for a collection of eight varieties of fruit was awarded to Mr. W. Marsh, Bath, who had fine, well-coloured bunches of Muscat of Alexandria Grapes, a good fruit of Sutton's Perfection Melon, Dymond Peaches, Pineapple Nectarines, Brunswick Figs, Goliath Plums, and Morello Cherries. Mr. J. Lloyd, gardener to Vincent Stuckey, Esq., Langport, was a close second, but staged Grapes that had previously done good service. Mr. T. Wilkins was third. In another class for a collection of eight dishes of fruit Mr. J. Lloyd was first; Mr. G. Garraway, Bath, was second; and Mr. W. Allen third. Local growers had also another chance of excelling with a collection of fruit. In this instance Mr. S. Bryant was first.

Mr. Marsh showed the best black Grapes in the open classes, well coloured clusters of Alicante, though these would have been beaten by the large and remarkably well "finished" bunches of Black Hamburgh shown in a local class by Mr. F. Bainton. Mr. J. Marshall, gardener to J. Dole, Esq., Clifton, was second with Gros Maroc in good condition. In the class for any white Grapes Mr. Marshall was first for a perfect bunch each of Muscat of Alexandria and Buckland Sweetwater; second, Mr. J. Lloyd. The other exhibits of fruit call for no particular comment beyond the fact that both culinary and dessert Apples were remarkably good, notably Lord Suffield, Warner's King, Peasgood's Nonesuch, Irish Peach, and Quarrenden.

Classes were provided for all kinds of vegetables in season, all of which were well filled, while the quality of the produce was first-class throughout. The numerous collections staged made a most imposing display. Mr. T. Wilkins was well first with a collection of eight varieties. Mr. G. Garraway was second, and Messrs. J. B. Woods and Son third. In the local class for a collection Mr. D. Jeffries was first, and Mr. A. Fox was second. The cottagers also made a grand display of fruit, flowers, vegetables, and honey.

Special mention ought to be made of the efforts of the ladies in classes for table decorations. Not only were the competitors numerous, but they displayed excellent taste throughout. The most successful were Mrs. T. Meaden, Miss Jessie Martin, Miss F. Bush, Miss Louisa Haskins, Mrs. J. Rogers, Miss Howes, and Miss Florence Bush.

SWANSEA.—August 26th.

Horticulturists in Swansea and the surrounding district are to be congratulated on their first horticultural exhibition. They succeeded admirably so far as the number of entrants, the high standard of the various charmingly arranged groups, the beautiful stands of cut flowers, and the highly creditable display of fruit and vegetables, were concerned.

For the best arranged group, occupying a space of 100 square feet, there were five competitors. The first prize collection was staged by Mr. G. Hawkins, gardener to Mrs. Turbeville; Mr. Farrant, Swansea, taking second honours, and Mr. Carpenter third, each showing creditably. In the class for a smaller group there were four exhibitors. The first prize went to Mr. R. Downing, gardener to H. Bath, Esq., Swansea; second, J. C. Gorvin, Esq. For six stove and greenhouse plants, distinct, Mr. Carpenter was awarded the prize; Mr. Bowen, Swansea, being a close second. The last named was successful with Ferns, showing well. The class for twelve table plants was a good one, Mr. Farrant winning; Mr. R. Crossling, Penarth, was second. Mr. Hughes, gardener to J. Taylor, Esq., staged the best Begonias.

Wreaths and crosses were well shown by Messrs. Treseder, Cardiff, and Barron, Swansea. The last named staged the best ball and bridal bouquet, both being creditable examples; Mr. Farrant taking second place. Mr. Pride was first for the best arranged epergne; and Miss B. Gibbon second. Mr. W. Treseder won for buttonhole and sprays, and Mr. Wm. Brown for the best arranged basket. Sweet Peas, Dahlia; and hardy annuals were well shown, also Asters, while in the Rose classes Mr. Ralph Crossling proved invincible.

Mr. J. Cleeve, gardener to J. H. Rogers, Esq., Llanelly, was first for a collection of fruit, with good Muscat Grapes, Williams' Pears, Rivers' Orange Nectarine, a good Melon, Peaches, and Plums. Mr. G. Hawkins was second. J. H. Rogers, Esq., took first for the best six dishes of dessert Apples, and followed up by taking the prize for a similar number of kitchen varieties. For a single dish of dessert Apples, Mr. Wilkins won. For six bunches of Grapes in three varieties, Mr. P. Richards was to the fore with creditable pieces, Mr. Hawkins taking second place. In the class for Black Hamburgh Mr. G. Davidson was a good first with medium bunches, splendidly finished. The best Muscats were staged by Mr. Richards, and Mr. Cleeve, Llanelly, the first named winning for any other black Grapes, Mr. Hawkins taking second place.

The Society's class for nine vegetables was well contested, Mr. Pleasants, gardener to T. Penrice, Esq., and Mr. Jones, gardener to N. Powell, Esq., were equal first, staging good produce. J. Morgan, Esq., third. Potatoes were put up in large numbers. For the best six dishes D. Thomas, Esq., was awarded the prize, J. H. Rogers, Esq., being a very good second. Mr. S. Pugh staged the best Tomatoes, Mr. Hawkins second. Mr. J. Crofts had the best brace of Cucumbers, and D. Davies, Esq., the best Runner Beans. Carrots, Celery, Leeks, and Onions were all well staged in their several classes.

Mr. W. Treseder, Cardiff, had a pleasing show of Dahlias and hardy flowers in variety. Messrs. Wm. Clibran & Sons, Manchester, sent hardy cut flowers in great variety, and Messrs. Kelway a very fine exhibit of Gladioli, Delphiniums, Gaillardias, and Dahlias.

THE YOUNG GARDENERS' DOMAIN.

Men of the Future.

As in previous quarters, marks of merit have been accorded to the literary productions of young gardeners. During the second quarter of the year, the greatest number was obtained by Mr. W. Tyndall, The Gardens, Charleville Forest, Tullamore, and a gold fountain pen was forwarded to him. He was, however, run dangerously close by another correspondent, who did not seem able to write for a few weeks. We have received the following acknowledgment from the recipient:—

Your kind letter, also the gold fountain pen, are received safely, for which accept my best thanks. Surely young gardeners ought to take advantage of the facilities offered in the *Journal of Horticulture* for recording some of their experiences, in the hope that some at least of the probationers may in due time be able to follow with credit in the footsteps of those able men who have done so much in raising the standard of gardening to its present position.—W. Tyndall.

P.S.—This is written with fountain pen.—W. T.

[Very well written too, indicating that the pen and the man are both good.]

The Means and Modes of Propagating Plants.

(*Continued from page* 204.)

As a general rule it may be stated that seed should not be buried below the earth's surface at a depth greater than its own thickness or diameter, though it may be safely assumed that the depth may be increased with perfect safety in the case of seeds of leguminous plants, which are large and bulky in comparison with the generality of seeds. Thus, the tiny seeds of the Auricula should be sprinkled on the surface, and dusted over with a little fine soil and sand, covering with moss until they have germinated, in order to promote and preserve surface moisture. Larger seeds, such as Onions, Carrots, and Parsnips, should be sown in drills made with the end or back of the rake, and have the ridge that is thus thrown up drawn over them. Peas and Beans may be set at a depth several times their thickness or diameter in shallow trenches made with a hoe. The smaller the seed the finer should be the soil for its reception; it must also be dry enough to crumble lightly when worked with the hand, and not so wet as to clot together in a pasty mass. Therefore, dry weather should be chosen for seed-sowing, and if just before a gentle shower, or when the weather bids fair to be showery, so much the better.

In propagation by bulbs or offsets, all bulblets should be placed in light soil at a depth equal to their own height below the surface immediately after removal from the parent plant, otherwise they will dry under exposure to the air, and lose vitality.

In propagation by slips or cuttings, slips which spring from the collar or upper portion of the roots of herbaceous plants, as in the Auricula or Chrysanthemum, or from shrub-like plants, as Thyme and Sage, are stripped away from the parent plant in such a manner as to secure a heel. The heel should then be trimmed with a sharp knife, and inserted in suitable soil, shading to prevent the leaves flagging. When slips are taken from the collar they will often have roots attached, and may be described as offsets, these usually growing rapidly. Want of success in many cases may be traced to neglect in trimming the heel or base of the slip, or properly preparing it for insertion, as a callus is produced more quickly on a smooth surface than it is on a ragged one.

In propagation by division the original plant is broken up, and each piece, which will be found to consist of stem, leaves, and roots, may be planted separately, and will soon form a young and vigorous plant. This mode of propagation is resorted to in the case of most kinds of herbaceous plants. Solomon's Seal may be cut into pieces, provided that each piece has an eye or bud. Border perennials should be divided in the spring when growth is commencing. They will then separate readily into portions, each replete with buds for its upper growth and roots for its growth below ground.

In propagation by runners, it is necessary to peg them down, or place a weight on them so as to keep them in position unmoved, and in contact with damp soil. Roots are then emitted, and in due time the young plants are removed, as in the case of the Strawberry.

In propagation by suckers, these should be separated with care, and cut away as near the parent plant as possible, so as to retain the roots which have issued from the stem, exercising care in their removal to bruise them as little as possible, otherwise they will decay.—C. W. M.

(To be continued.)

Mignonette in Pots.

This sweet-scented flower is appreciated by everybody, and never more so than when grown in pots for winter flowering. Many growers sow a few seeds in 5-inch pots, and after thinning the plants to four or five grow them on and flower them without giving any shift whatever. This method is a good one if only a small quantity of bloom is desired, but where an abundauce is looked for the following method, though an old one, will be found to answer well.

Seeds should be sown the first week in July in 4-inch pots, containing a mixture of two parts rich fibrous loam, one part broken mortar rubble, and one part leaf soil and sand, the whole being thoroughly mixed together and made firm in the pots, which may be assigned to a position on a bed of coal ashes in a cold frame having a north aspect. One good watering with occasional syringings will suffice until the seedlings are large enough to thin. This should be promptly done, leaving four plants in each pot. When the plants have made six leaves stop them, the result being several side shoots.

As soon as the roots have well filled the pots, and before they become matted together, give the plants a shift into 8-inch pots, this time using a eompost consisting of loam two parts, mortar rubble one part, sand and old Mushroom bed refuse one part, with a good sprinkling of soot and some approved artificial manure. The mortar rubble is an important part of the compost, inasmuch as it keeps the soil open and sweet. The potting requires to be firmly done, and the soil should be in just such a friable condition as will allow of its being rammed without any fear of it adhering to the potting stick.

Throughout the entire season of growth the plants ought to be kept in the frame quite close to the glass, as much air as possible being given, and the lights put on only at night or during showery weather, and then well tilted. Towards the end of September remove the plants to a shelf in a cool house where they will receive plenty of light. Watering must at all times be carefully done, each plant being examined. As the plants gain in size peg them down until the pots are well covered, staking as required and removing every flower until the beginning of November. Liquid manure and soot water is useful now as a stimulant, and the plants will attain to almost bush-like dimensions, covered with large spikes of flowers, at a season when cut flowers are none too plentiful viz., November onwards for many weeks.

The essential points to remember are - timely thinning, cool treatment, firm potting, and cautious watering, which if carefully attended to are certain to give good results.—Youngster.

Culture of the Grape Vine.

The Grape Vine, botanically named Vitis vinifera, has long taken a foremost place amongst the choicest fruits of the land, not only for use as dessert, but from its juice we get our best wines. It is not intended to give an historical sketch of the Vine, although that might be very interesting to readers of the "Domain," but to give a few notes on the cultivation of this grand fruit as observed by the writer. Let us hope I shall succeed in my endeavour, but should I err in any of my statements I trust I may be put on the straight path.

Propagation.—There are many ways of increasing the Vine namely, by budding, grafting, inarching, layering, euttings, eyes, and seeds. It is intended in this article to deal only with eyes, as that mode of propagation is mostly practised by private gardeners. Commence by preparing a sufficient number of clean 3-inch pots by well draining, and firmly filling with a compost consisting of good loam, leaf mould, and sand. Make a hole in the centre of the pot, so deep that when the wood is placed in it the eye just protrudes above the soil. In preparing the eyes select well ripened wood with prominent round eyes. Cut the wood through at about half an inch from the eye each way, the cuts being made diagonally from the top downwards. About a quarter of the wood is cut off from the side opposite the eye. All is then ready for insertion. When placing the eye in the pot it is better to let the wood rest on sand, as this tends to keep it sweeter, and so quicker root action is aided. Draw the soil round the eye, making all firm, afterwards sprinkling silver sand on the surface of the pots.

From the middle of January to early in February is the best time to perform this operation. When all the eyes are inserted, plunge the pots in a bottom heat ranging from 75° to 80°. The temperature of the house should be about 70° by night, with a proportionate rise by day. Should the soil not be thought sufficiently moist, afford a light watering, care being taken not to get the compost too wet or failure will ensue. When the young plants are well rooted and growing nicely, remove to 6-inch pots, using a eompost as before, only the loam should be rougher and more fibrous. If these pots ean be plunged in bottom heat so much the better. When well rooted take the plants from the plunging material and stand them as near the glass as safety will permit, in order that sturdy, short-jointed wood may be formed.

Use the syringe freely about the foliage, both in the morning and at closing time, not only to keep away insect pests, but to aid a clean, free growth. Air should be admitted very sparingly at first, gradually increasing the amount as the days become brighter and warmer, but on no account allow so mueh as to eripple the young growths and tender leaves. Pinch the laterals when they have made one leaf, but do not stop the leader; let it run as far as it likes, tying down to avoid entanglements. As the pots fill with roots an oceasional application of some proved fertiliser is very beneficial.

Assuming the plants are nicely growing, we will leave them for a time, and turn our attention to struetures for Grapes, borders, and planting.—Semper.

(To be continued.)

FRUIT FORCING.

Cucumbers.—As the days become shorter and the nights colder, closing the house earlier, also syringing sooner, must be attended to in order to secure as much advantage as possible from sun heat and prevent exeess moisture on the foliage during the night. In cold, wet weather fire heat becomes necessary to secure clean, straight fruits, maintaining a temperature of 70° to 75° by day and 65° to 70° at night. Allow the heat to rise to 85° or 90° from sun heat, and close so as to secure the latter temperature to 95° or more for some time in the early part of fine afternoons. Keep the growths fairly thin, removing old shoots so as to make room for young ones, and thus provide a succession of bearing parts. Stop the shoots one joint beyond the fruit unless growth is wanted, then allow more extension, always, however, avoiding crowding. Encourage root action by a steady bottom heat of 80°, surface dressing with lumpy loam and sweetened horse droppings, and sprinkle a small handful of soot on each square yard of bed. This gives the fruit a fine deep green colour —a point of considerable importance—besides promoting the health of the plants, and with liquid manure in a tepid state whenever water is required secures an abundant crop. Do not, however, overcrop; but the output can be materially augmented by cutting the fruit directly it becomes fit for use.

Autumn Fruiters.—The foregoing remarks apply to plants in bearing some time, and to these in measure of temperature and nutrition, but the autumn fruiters will only require stopping to insure an even spread of foliage, and on the corresponding bearing growths keeping tendrils and male flowers removed. The plants will now bear the sun unshaded, avoiding morning syringing, and only using it on fine afternoons, then lightly and early, keeping the house damp as required. Ventilate in moderation, avoiding draughts, as they chill and stunt the growths and fruits, and if no air is given the foliage becomes thin and flabby, yet a somewhat close, warm, and moist atmosphere is necessary for clean growths in both shoots and fruits. Remove the first shows of fruit on weakly plants, and seek to encourage sturdy, thoroughly solidified growths by judicious ventilation and gentle fire heat when needful.

Winter Fruiters.—The plants from seed sown in August will now be ready to plant out. The house being a light one, the heating means adequate to maintaining a temperature of 70° to 75° in all weathers, with a bottom heat of 80° to 90°, the prospect of having Cucumbers in winter are favourable, not otherwise. First of all thoroughly cleanse the house, removing every particle of old soil, and scalding the whole of the interior with boiling water, then wash the woodwork with petroleum, softsoap, or carbolic soap, water and a brush, cleansing the glass with elear water, limewashing the walls with hot lime and a small handful of flowers of sulphur in each pailful. If rubble is used about and over the pipes for bottom heat see to eleaning it by taking out and washing. Make the drainage secure with a layer of turves previously eharred or scalded. Put in hillocks or ridges of soil 2 feet wide at the base, 10 to 12 inches deep, and 1 foot across at the top. Turfy loam laid up until the grass is killed (and with it 14 lbs. of basic slag phosphate and 7 lbs. of kainit per cubic yard), chopped up rather roughly, two-thirds; fibrous sandy peat one-third, chopped or torn up, rejecting any woody matter; old mortar rubbish freed of laths and other pieces of woody substance, the rough broken small, form, thoroughly incorporated, a suitable compost. Being neither wet nor dry, it may be made moderately firm.

Plant when the compost is warmed through, press the soil gently, and seeure the plants to stakes reaching to the trellis. Rub off the laterals to the bottom wire, and stop the leading growth at about the second or third wire of the trellis. Shade from bright sun until established. Syringe on fine afternoons lightly and early, damping in the morning, at noon, and early in the evening. Maintain a day temperature of 70° to 75°, 85° to 90° from sun heat, and a night temperature of 70°, falling to 65° or even 60° in the early morning. The plants thus attended to will fruit in late autumn, but they must not be cropped too much if they are to give a plentiful supply from Christmas to the spring.

Where seed was not sown in August, and Cucumbers are required at the new year onward, sow early in this month. The varieties are legion; none is better than Improved Telegraph, Rochford and Cardiff Castle being excellent. Snow's Winter, a very old variety, and seen in the Syon House type, may not now be procurable, otherwise it has no equal for swelling in the winter months. Sow the seed singly in small pots a little more than half filled with soil, and cover half an inch deep. Keep the plants near the glass, and earth them up as they grow, and transfer to 5-inch pots when they need a shift, placing a stick to each, to which secure the growth as it advances. Train with one shoot by rubbing off the laterals as they show. The plants will be fit to place out during the first fortnight of October.

In Pits and Frames.—If the growths are trained somewhat thinly, watering done early and judiciously, the plants will continue in bearing some eonsiderable time. A light sprinkling of water may be given at closing time on fine afternoons, but it will not be much needed after this, or very little of it, the plants deriving sufficient moisture through the decay of

the fermenting beds. Line the beds with sweetened stable litter, and admit a little air at the back to allow of any rank steam escaping. The night temperature should be kept at 65°, a little air given at 75°, and keeping through the day between that and 90°. On cold nights employ a covering of mats over the lights.

Melons.—The fruit ripening is improved in flavour by a brisk heat in the daytime, and with sufficient ventilation to insure a circulation of air constantly. Keep water from the house and the soil somewhat dry as soon as the fruit commences ripening, supplying moisture only to prevent flagging. Melons are really good in September if well ripened, and so also are October ones. The later fruiting plants have the Melons in an advanced swelling condition, and will be assisted by a little weak liquid manure. Keep the laterals well in hand, but not very closely pinched where the old leaves are not in a healthy state, and have a sharp eye on red spider, applying a little sulphur to the pipes, vapourising with nicotine essence or fumigating with tobacco paper for aphides and thrips, while for canker rub quicklime into the affected parts, repeating as necessary. If cracking occurs cut the lateral about half through a little below the fruit. It will check the flow of sap and afford some relief if accompanied by a circulation of air constantly. But the chief cause of cracking is stunted growth in the early stages of swelling and when nearing ripening, a moist soil and a close moist atmosphere causing the deposition of moisture on the fruit during the night. Ventilate freely, and keep the air moderately dry by a little ventilation constantly as a preventive of canker and cracking.

Latest Melons.—The plants now are well up the trellis and showing fruit blossoms; these should be fertilised daily, keeping the atmosphere rather dry, a little ventilation being given at night so as to insure a circulation of air and prevent the deposition of moisture upon the blossoms. Stop the shoots at the time of impregnation one joint beyond the fruit. As soon as a sufficient number of fruits are set on a plant, remove all staminate and pistillate flowers, reducing the fruit to three or four on a plant, or according to their vigour. Earth up the plants after the fruit is fairly swelling, and be careful in syringing the foliage, only using it on bright afternoons, but maintain a genial condition of the atmosphere by damping in the morning and afternoon. Be careful not to give too much water, but encourage healthy root action by moderate moisture in the soil. Maintain the temperature at 70° to 75° by day, and 80° to 90° from sun heat, with 65° to 70° at night.

Melons in frames and pits will not require further damping over the foliage, and should only have sufficient moisture in the soil to preserve the plants in health, keeping the foliage thin, and the fruit well raised above it on flower pots, each fruit resting on a piece of slate. Apply good lining for affording the requisite heat to finish the fruit properly, and maintain a dry atmosphere with free ventilation. Damp ruins Melons in frames late in the season.

Strawberries in Pots.—Runners not over early rooted on account of the dry weather may now be placed in 5 or 6-inch pots, and getting well hold of the soil and given due exposure in the autumn, the plants will produce some good fruit in April and May, though not so plentifully and large as those potted earlier. For introducing to heat in January and February we have found them excellent, especially Noble, Vicomtesse Herieart de Thury, Royal Sovereign, Sir Joseph Paxton, Lucas, Gunton Park and British Queen.

Plants potted some time ago should be examined and if making side buds too numerously, they, where fine fruits are desired, should be removed with a piece of hard wood, so as to throw the vigour into the central crown. If the plants grow vigorously liquid manure will not be required, but those that are weakly should have supplies of it twice a week. Remove all runners as they appear, and loosen the surface of the soil, especially round the sides of the pots, so as to secure the more thorough and even moistening of the ball. As the plants grow set the pots wide apart. If red spider attack the plants hold each inverted with one hand, and with the other dust the under sides of the leaves with a mixture of air-slaked chalk lime, flowers of sulphur, and soot in equal parts, finely sifted and applied by means of a dredger.

THE FLOWER GARDEN.

Ageratums and Heliotropes.—Sowing seed in the spring is the best way to raise Ageratum plants. Those obtained from cuttings are, however, the most compact, and, if desirable, a stock might yet be propagated with a view to having abundance of cuttings next spring. Select soft, flowerless tops from the best plants, and dibble them thinly in 5-inch pots, placing in gentle heat. Old plants of both Ageratums and Heliotropes often fail to lift well, but if a number of the latter have been kept for flowering in pots during the autumn and winter, these will produce abundance of cuttings next spring. Failing these root a good number of tops as advised in the case of Ageratums.

Verbenas.—There is no lack of soft clean cuttings on Verbenas, and abundance of these must, if not already done, be taken off and rooted. It is the young flowerless shoots that should be preferred, and these ought to be shortened to the third joint, dibbling them before they flag badly in well drained 5-inch pots filled with a mixture of fresh loam, leaf soil, and sand. A partially exhausted hotbed is the best place to root them on, and they should be kept close, shaded from bright sunshine, and moist till rooted. Much dry heat ruins either cuttings or well rooted plants.

Zonal Pelargoniums.—If cuttings are soft and sappy they are somewhat difficult to root and save. The old-fashioned plan of preparing the cuttings for pots and pans, and then spreading them out in the sunshine to flag and dry for a whole day or two, gets rid of much superfluous moisture, and has much to recommend it. Late rooted cuttings can be wintered most surely in 4-inch or slightly larger pots, as these can be stored thickly on shelves in cool dry houses. In these the cuttings may be dibbled in quite thickly, giving them more room in the spring. At this late date they must not be exposed to showery weather and heavy fogs and dew, but should have the benefit of glazed coverings, and all the light, air, and sunshine possible. No water ought to be given at first, and only enough later to keep the stems from shrivelling badly.

Iresines, Coleuses, and Alternantheras.—Rooted cuttings are preferable to lifted old plants, even when the latter recover well from the check. The first frost will cripple these delicate bedding plants, and no time, therefore, should be lost in rooting a number of young tops. Use 5-inch pots well drained and light soil. Place six cuttings in each pot and root them in heat. All are liable to damp wholesale, and the frames or glass covering them will require to be well dried every morning.

Fuchsias.—These are now very popular as bedding plants and also for plunging separately on the turf. If young flowerless shoots can be had, these might be rooted in pots or pans in heat, much as advised in the case of Verbenas. Instead of wintering them in the cutting pots the better plan would be to pot them separately, and keep them steadily growing all through the winter. They sometimes make good pyramids without any pinching other than stopping the side shoots, but more often they require to be stopped frequently in order to form a good bottom, after which a strong central leader may be trained to a stake, this and the side shoots being pinched back as often as flowering threatens. A moist gentle heat suits Fuchsias, and they must not be allowed to become badly root-bound prior to shifting into larger sizes.

Narcissi and Daffodils.—These are rightly extremely popular, and no class of bulbous flowered plants better repays for the little trouble necessary to take with them. The commoner kinds, notably of the Polyanthus Narcissus intended for the flower beds, must perforce be kept out of the ground some time longer, but there should be no further delay in the case of the choicer sections. In many positions the latter succeed well when not disturbed oftener than every third year, but some few of the delicate species require to be moved more frequently. If single bulbs of rare or expensive varieties are planted from 4 inches to 5 inches deep in good loamy soil they will flower next spring, and also form several offsets, which will attain a flowering size in the course of two seasons, always provided they are not detached from the parent bulb too quickly. The present is also a good time for lifting, sorting, and replanting any species that last season gave signs of either failing health or of being unduly crowded. Plant all the medium-sized to large bulbs either in lines or thin groups where they will be best seen, and they are suitable plants for fruit borders alongside garden walks, and the smaller offsets in nursery beds. The common Daffodils and Pheasant-eye Narcissi may also now be procured for growing in shrubberies, alongside woodland walks, and such like. They are well adapted for planting under the turf in patches or singly, as they flower and die down again before it is necessary to mow the grass.

Alstromerias.—There would be fewer failures with these if more judgment were exercised in the selection of sites. They fail in cold sites and heavy soil, and succeed admirably when planted in the narrow warm borders often formed close up to sunny house fronts. Plant rather deeply and do not disturb again for many years. Under this treatment they will increase rapidly and flower grandly every season.

Irises.—The bulbous rooted species of these beautiful plants ought to be taken up, divided, and replanted every second or third season. They all succeed well in a fresh, moderately rich, and not too heavy loamy soil, this being worked to a good depth. Plant from 6 to 8 inches apart and 4 inches to 5 inches deep, and surface the beds with Pansies, Violas, Alpine Auriculas, or other plants that will not take more than their share of food and moisture out of the soil. Plant new bulbs as soon as they can be had.

Various.—Crocuses permanently planted in borders should be lifted, divided, and replanted every third or fourth autumn. If returned to the same site give a change of soil, and always bury the bulbs 4 inches deep. Snowdrops can be lifted, separated into patches, and replanted without detriment to their flowering next season. They move best after fresh roots have been formed. Either these or newly purchased bulbs should be buried 2 inches deep. During this month plant Cyclamen Coum and C. europæum. These are rockwork plants, and should have a sheltered position and light sandy soil to grow in. They are most effective in groups of threes. Triteleia uniflora flowers very early and grandly at the foot of sunny fences or walls, and when in bloom is only slightly checked by severe frosts. Plant in groups of nine or more bulbs, and 2 inches deep. Treat Jonquils similarly to Narcissi.

THE KITCHEN GARDEN.

Cauliflowers.—Caterpillars are very plentiful this season, and unless well looked after they soon spoil Cauliflowers. Tying up the leaves closely over the centres soon after the hearts commence forming excludes butterflies, and leads to the perfect blanching of hearts. Those who desire extra large Cauliflowers should apply liquid manure to the roots freely directly they commence hearting-in. With the introduction of quick maturing varieties there has been less need to sow seed in the autumn with a view to having strong plants for hand-lights or frames than formerly. There is yet much to be said in favour of the practice. Sow seeds now, or not later than the first week

in September, on a sunny border, and winter a portion of the plants in hand-lights, frames, or on cool greenhouse shelves in pots. If the first sowing fail owing to neglect to protect from birds, slugs, or Turnip flea, sow more seed broadcast in shallow frames, and do not disturb the plants till next March. By sowing seeds of Autumn Mammoth and Autumn Giant with the earlier varieties it will be possible to have these fine varieties fit to cut late in July and onwards.

Mushroom Beds in Outhouses.—Mushrooms can be successfully grown in snug outhouses, more especially those with thatched sides and roofs, through the late autumn and greater part of the winter months. They fail in very cold weather only, always provided the beds are properly protected with strawy litter, and are not spoilt by overmuch water. The same remarks apply to disused cellars. In these instances the beds should be formed of thoroughly sweetened droppings from horses in full work and fed on hard food, leaving only the shortest straw with them. While in preparation by fermentation the heaps of these droppings should be turned inside out sufficiently often to prevent them becoming overheated in the centre. They ought to be gently watered whenever they become dry, and must be protected from saturating rainfall. Form nearly flat beds, not more than 15 inches deep at the back and 12 inches deep in front, after the manure has been trampled or beaten down as firm as it can be made. The heat should soon rise to about 85°, spawning taking place directly it has declined about 5°. Plunging thermometers can be dispensed with, and the condition of the bed arrived at by means of sticks forced in the bed. When the plunged portion of these can be borne comfortably in the palm of the hand spawning may safely take place. Use moderately large lumps of spawn, opening shallow holes 8 inches apart for these with the hand or trowel rather than with a dibber. Dispose the spawn flat surface upward, burying it nearly flush with the top of the manure, and packing the latter firmly about it. If there is no likelihood of the heat rising to an injurious extent cover the beds with about 2 inches of fresh fine loam three days or so after spawning, and soon after cover the beds with 6 inches of soft strawy litter. New spawn should be employed, and an excess of either heat or vapour be guarded against.

Onions.—When the tops die down, or as soon as the roots come away readily from the ground, Onions should be drawn and well harvested on wattled hurdles, or in dry positions, ready for storing. Any late in maturing to have their tops twisted down. If the weather prove unfavourable for harvesting Onions in the open, spread them on stagings in early vineries, or on a dry base in empty glazed pits, turning them occasionally. They will not keep well unless thoroughly harvested. Seed of both Tripoli and White Spanish Onions may now be sown, the plants obtained standing out through the winter and maturing next season considerably in advance of any sown in the open in March. A well-prepared, sunny, open spot should be selected, and the seed be sown thinly in shallow drills wide enough apart to admit of hoeing between.

Tomatoes under Glass.—Where houses are wanted for other purposes during the winter, fruit set later than the first or second week in August will not have a chance to ripen. All superfluous growth should, therefore, be freely shortened back to near where the fruit is swelling or ripening, as the case may be; also cut away all badly diseased leaves, of which there are only too many this season, a very few of the younger or green leaves left near the fruit serving to keep up the life of the plants. Fire heat, coupled with a moderate amount of air, hastens the ripening, also prevents cracking of the fruit. Plants that are to produce ripe fruit during the winter should have the same treatment as regards fire heat and ventilation, as, unless the crops are set during the next few weeks, there will not be many fruits to ripen in the winter. Train thinly up the roofs, and if the old leaves are diseased reserve the side shoots that form thinly about the stems and top these, otherwise there will soon be no leaves to draw up and elaborate the sap. Painting the pipes with sulphur mixed with skim milk and making them thoroughly hot occasionally serves to check the spread of disease, and so also does coating the leaves with a mixture of sulphur and newly slaked lime applied with the aid of a bellows or other distributor. Plants that have already set good lower clusters of fruit must be fed liberally at the roots, or the later bunches of flower will fail to give fruit. A good circulation of warm dry air is favourable to the setting of fruit, and to the prevention of the spread of fungoid diseases. A few hours of a warm moisture-laden atmosphere, such as suits Cucumbers, means a bad attack of cladisporium and other diseases this season.

Lifting Tomato Plants.—Plants, both against walls and quite in the open, have set excellent crops of fruit, but the ripening is slow and a partial failure is threatened. The smooth round varieties are usually the first to suffer from disease and are most given to cracking. In order to be certain of the crops of these ripening it is advisable to lift a portion or all of the plants, and either place in pots or boxes or else replant temporarily under glass. When pots or boxes are used these should be large enough to hold a moderately large ball of soil and roots, and the potting or boxing ought to be done where the plants are growing, using ordinary soil and at once carrying them to a warm dry house, where if need be they can be shaded from bright sunshine for a few days. A roof newly cleared of Cucumbers or Tomatoes might be partially re-covered with Tomato plants set with large fruit, moving these in boxes with one side only, and sliding them on to the ridge of soil that supported the previous crops. Pack them closely together, making the soil firm and level about the roots, keep them well supplied with water, and shade from bright sunshine.

PLANT HOUSES.

Poinsettias.—These if brought forward under cool conditions will be sturdy plants with foliage to the base. Give more air during bright warm days; in fact, no harm will result if the lights are thrown off for a few hours during the hottest part of the day. Do not excite the plants into fresh growth by closing the frame too early in the afternoon. It will be wise to close it at night. Weak stimulants may be given occasionally, or better still, apply a little artificial manure to the surface of the soil. When the pots become filled with roots feeding must be resorted to, or the lower leaves will turn yellow and fall.

Euphorbia jacquiniæflora.—Well established plants may be given the same treatment as Poinsettias. Those in a more backward condition may be encouraged to grow, but must be fully exposed to the sun and given a free circulation of air daily. Firm sturdy growth must be made or they will fail to flower satisfactorily. Centropogons and Justicias may be grown under the conditions advised for these plants.

Crotons.—Good heads that need re-rooting should be moved at once. Side shoots that are well coloured may be taken off and rooted without delay in small pots; these will be found useful during the winter. Small plants that are well rooted may be placed into 4-inch pots and arranged on a shelf close to the glass in a warm moist structure. In this position the plants will colour freely and make capital decorative material before winter. Few plants are more effective than Crotons when well coloured for grouping during the winter months when flowers are scarce.

Gardenias.—Clean these thoroughly if infested with mealy bug by an application of petroleum and water; this should be continued at intervals until every trace has been eradicated. After syringing them with the solution a light shade should be applied until the oil has been evaporated. If plants are grown annually from cuttings they ought to be rooted at once. Select for this purpose young soft growths, which may be inserted in thumb pots, as every one will root in brisk heat if kept close and shaded from the sun.

Gloxinias.—Where these are appreciated, plants that flowered early and have rested may be shaken out of their pots and started again into growth. Young stock raised from seed will also flower profusely if they are placed into 4 and 5-inch pots. Do not grow them too warm, but shade them from bright sunshine.

Panicum variegatum.—Insert cuttings thickly into 3, 4, and 5-inch pots. They will root freely in a close shady place. A good stock of these plants are always useful for grouping during the autumn and winter. To have them in good condition no time should be lost in starting them, for unless well established they do not look well. A good stock of Mosses, Coleus, Fittonias, and other variegated plants should now be prepared.

Adiantum cuneatum.—If the fronds of these are to be of service when cut the plants must be grown freely exposed to the sun and given air daily; in fact, the fronds stand best when the plants are prepared in a cool house fully exposed at this season of the year. Plants that have yielded fronds for a long time, and have rested in a cool place, may be started into growth in heat. They will soon push up fresh fronds and yield a good supply for winter. Young plants in various stages of growth may be repotted if they need more root room. They will grow strongly and continue to produce capital fronds until February. Seedlings may be placed singly into thumb pots. Where seedlings are raised annually it is a good plan to place pieces of turf underneath established plants that have old fronds upon them. The spores will fall upon the turf and germinate freely. This is the easiest method of raising a stock of young plants.

Eulalias.—For grouping these are invaluable, and they are exceptionally effective in conservatories of large size. Plants that were divided in spring and have filled 6-inch pots with roots may be placed into others 2 inches larger. They increase much more rapidly when given liberal root room. When grown mainly to yield stock the plants should have a position where an intermediate temperature can be given them, as they increase much more rapidly than under cool conditions. Plants that are repotted now will continue growth until late in the year, and can be cut up into several good pieces next spring. Seed can be easily saved, but so far we have only succeeded in raising plants with green foliage. These, however, are useful, and afford variety if associated with other plants of a suitable nature.

POTATO DISEASE.—We are informed that a good deal of disease has appeared in Devonshire. Those Potato plots dressed with Bordeaux mixture have the foliage still standing, but the leaves of adjoining undressed plots have decayed. The sulphate of copper and lime have done good service, although some persons would not have wept if no good had followed the demonstration.—C. B.

THE BEE-KEEPER.

Queen Introduction.

It is advisable to examine all stocks at this season to ascertain if they are headed by fertile queens, as the future success of each colony depends, to a certain extent, on this being the case. There is no comparison between a stock of this description and one that is headed by an old worn-out queen. It may not be so apparent at this date as it will be next spring, as many old queens die during the winter. It is, however, useless raising young queens unless one has a simple plan of introducing them to strong colonies, and this can only be accomplished by close attention to detail. It is quite possible to remove a condemned queen from a colony and at once place another on the same comb without any harm coming to it. It is a plan, however, not to be recommended, as it would more often end in failure.

Caging Queens.

More queens are introduced by caging them than by any other means. It has the advantage, too, of being safe when properly carried out. Still, numerous instances have come under my notice where it has not been a success. The cause of failure could usually be traced to what the operator would at the time think a very trivial matter. The old queen should always be removed before the young queen is introduced. This is best done in the middle of a fine day, and if the sun is shining brightly so much the better, as during dull weather bees will cluster somewhat closely on the combs. It is then not so easy to find the queen as during a bright spell of weather when they are more thinly distributed.

Lift the frames one by one out of the hive and run the eye quickly over them, and with a little practice the queen may be found quite easily. There are numerous cages recommended for the purpose, some of which are much better than others. But the one I prefer, and always use, is home made and answers the purpose admirably. It has the advantage of being cheap, so no bee-keeper should be without one. It is made thus:—Take a piece of perforated zinc about 6 inches square, turn the edges down about half an inch. This will form a box without a lid. This is placed over the queen and pressed firmly into the comb. Whilst this is being done the queen and comb should be taken into a room, otherwise she may fly away and be lost. Place the frame in the middle of the brood nest and cover up warm. Forty-eight hours afterwards liberate her by simply removing the cage, and the bees will take readily to her. If from any cause the bees are inclined to ball her, cage her again for twenty-four hours.

Direct Introduction.

If a stock of bees is queenless, and the owner has no means of raising a young queen, direct introduction is recommended. But if there is a doubt as to them being queenless then caging is preferred. But if the condemned queen is removed in the middle of the day and the bees are again covered up warm, the young queen may be safely introduced the same evening, the later the better. Having first secured the young queen and placed her in a box quite alone—a matchbox answers the purpose admirably—place the box containing the young queen in a warm place until evening; then take a light and the box containing the young queen to the stock from which the old queen has been removed, lift a corner of the quilt, and with a puff or two of smoke drive the bees down between the frames; open the box and allow the queen to run down; replace the quilt and coverings, and do not examine the stock for at least forty-eight hours. By this means queens may be successfully introduced without failure, and as it has the advantage of being simple should be more generally practised than it is. If the bees have ample stores it is still advisable to give them a little syrup for a few days, when it may be withheld altogether.

Balling Queens.

This is usually the result of carelessness on the part of the bee-keeper; or, as will happen when a queen goes into a wrong hive, as is often the case with young queens when on the wing, before being fertilised. When this occurs they are at once balled by the rightful owners of the hive, and in this way she is killed; sometimes the cluster of bees surrounding her is as large as one's fist. By this means she is suffocated. A queen is sometimes balled for at least twenty-four hours before being cast out of the hive; often the strange queen is seized before she is able to gain an entrance to the hive. She is then balled in the same manner. When this is observed it is pretty certain to predict that it is a queen from one of the other colonies.—An English Bee-keeper.

TO CORRESPONDENTS

*** All correspondence relating to editorial matters should, until further notice, be directed to "The Editor," 8, *Rose Hill Road, Wandsworth, London, S.W.* It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Exhibiting Vallotas as Liliums (*J. J. K.*).—By no stretching of interpretation can Vallotas be made admissible in Class II. for a pot of Liliums, as Vallotas belong to the natural order Amaryllideæ, and under the most favourable definition the term "pot of Liliums" ought to be confined to genera of the natural order Liliaceæ. Strictly, however, a pot of Liliums means species or varieties of the genera Lilium. The alteration to "Lilies" would render Vallotas admissible, but that clearly is not the meaning of the term "Pot of Liliums in Bloom." As for Class I., "Three Plants, distinct species," a pot of Vallotas and a pot of Amaryllis could be shown in strict accordance with the schedule, as there would not only be distinct species, but different genera.

Gravenstein Apple (*Venus*).—We do not know an Apple bearing either of the names you cite; and although it is often difficult to identify a variety by the inspection of a solitary fruit, we suspect the fine specimen you have sent is the Gravenstein. We are not surprised to hear of its being "a favourite with the youngsters" as its fine appearance, tenderness, and sweetness when ripe would account for that, and the same qualities equally render it a favourite with persons who have advanced far along the journey of life. It is one of the favourite Apples of Germany, particularly in Holstein, where it is said to have originated in the garden of the Duke of Augustenberg at the castle of Grafenstein. We have seen Apples exhibited under the name of Gravenstein, which were certainly not "true."

Tomato Fungi (*C. B. W.*).—The "black spot" or "black stripe" fungus (Macrosporium tomato) is distinct from the "scab" fungus (Cladosporium fulvum syn. lycopersici), and though in some respects similar in their effects on the fruits, are very different in their action. "Black stripe" fungus very rarely breaks through the skin of the fruit, but converts the pulp into a black mass. It is not of English, but American, origin, and has probably been introduced into this country in seed. Scab fungus also is not British, but has been introduced, probably from America. It is semi-epiphytic, works in or just beneath the skin of the fruit, which it breaks through and bears innumerable spores, but on the leaves produces these most abundantly, so much so that showers of yellow or brownish dust-like conidia are scattered when touched. It readily yields to dusting with a powder fungicide containing 10 per cent. of sulphate of copper. Not so the "black stripe" fungus, for it is almost wholly endophytic, and cannot be got at by external dressings once it gets hold. It is unquestionably the worst enemy of the Tomato fruit, and must not be confounded with the Cladosporium and Macrosporium sometimes attacking Potatoes and Tomatoes, and frequently associated together in the self-same infection.

Diseased Grapes (*Pyke*).—The bunches are infested by the Grape anthracnose fungus (Sphaceloma ampelinum or Glæosporium ampelophagum), and easily distinguished from all other Grape diseases by its characteristic and peculiar injury. It attacks all the green parts of the Vines, but in this country chiefly the shoots and fruit. On the shoot there first appear small round brown spots, and as the disease progresses they become depressed owing to the death of the tissues. The effect on the fruit first appears as a small greyish spot, with a dark brown margin. This spot gradually enlarges, and has a vermilion coloured wing just inside the dark brown margin, hence the name, at this stage, of "Bird's-eye Rot." The fungus pursues its way, checks the growth of the berry, and it finally becomes a dry, withered mass of skin, surrounding the partially developed seeds, which is well seen in the smaller of the two bunches. Nothing could be more characteristic. The bluish mould has nothing to do with the disease. The spores of the fungus are produced here and there just beneath the cuticle, which burst through and escape, setting up the disease over extensive areas. The diseased Grapes should be cut and burned, but the disease may be arrested or kept from spreading by using a powder of air-slaked lime and flowers of sulphur in equal parts. In winter, burn the prunings and dress the Vines with a solution

of iron sulphate (copperas), 1 lb. to 1½ gallon of water, applying with a brush, removing the loose bark, but not peeling the rods into the live bark. As a preventive in the spring dust the Vines as soon as the bunches commence developing with the lime and sulphur mixture, and repeat at intervals of three weeks till the berries are half grown. If the houses and Vines are properly dressed in winter the anthracnose is not likely to appear.

Diseased Chrysanthemum Leaves (*I., Maidenhead*).—The leaves are infested by the leaf-rust fungus (Trichobasis Artemisiæ) a rather uncommon parasite on the Chrysanthemum, but destructive when it does occur. The spores are very abundant on the specimen, the tissues of the leaves being almost destroyed by the mycelial hyphæ of the fungus; hence we should remove the worst affected leaves, but not until after spraying the plants on the under side of the foliage with potassium sulphide solution, half an ounce to a gallon of water, in order to destroy as many spores as possible. The best preventive of the infection is dusting the plants occasionally with a preparation of sulphate of copper in powder, such as the advertised fungicides called antiblight and fostite, applying with a bellows apparatus, coating the leaves as made with the finest possible coating and delivering upward, so as to distribute the poison chiefly on the under side of the foliage.

Preparing Carnation Border (*J. S.*).—On a light soil the best plan is to dress it with marly clay, using about half a cartload per rod, and either allowing it to lie on the surface till dried through, then pounding and digging in, or let frost act upon it, then when fallen, as it will after a thaw, mix with the soil evenly by digging with a fork and taking small spits. Thoroughly decayed manure could then be applied, and either dug in or left on the surface till near planting time, for Carnations like thoroughly sweetened material. As for the wireworm and also eelworm (Tylenchus devastatrix), the best preventive we have found, after several experiments, to be mustard dross, but it has a pernicious effect on vegetation, and must not be used over growing plants. For general purposes it suffices to use 1 oz. per square yard, not more, if anything rather less, or 1¾ lb. per rod, 2½ cwt. per acre. Specially for wireworm and as a preventive we advise the mustard dross, distributing it evenly and leaving on the surface or very lightly pointing in. Then supply basic slag phosphate 7 lbs. per rod, and kainit 3½ lbs. per rod, pointing in in the autumn and leaving until spring, when the land may be dressed with decomposed manure, if humus be needed, and superphosphate with quickly acting potash and nitrogen, nitrate of potash, and some gypsum (sulphate of lime). This we have found the best way of treating land infested with wireworm, eelworm, and white worm, and giving the best results in crops, especially of flowers, seeds, and "roots." If you do not use the foregoing a dressing of gas lime would be of service, as it would kill all wireworms reached and leave sulphate of lime behind, or rather the gas lime would gradually become that or gypsum. Quicklime is not a desirable dressing for light land, as it eats the "heart" out of it, but it is good against wireworm, eelworm, white worm, and, above all, finger-and-toe fungus. We do not, however, advise either in your case.

Names of Fruits.—*Notice.*—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. *In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing.* The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. *They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state.* (*F. H.*).—1, Beurré d'Amanlis; 2, Nouveau Poiteau; 3, Devonshire Quarrenden; 4, unknown. (*D. C.*).—1. Emperor Alexander; 2, Ribston Pippin; 3, Gravenstein; 4, Sandringham; 5, Roundway Magnum Bonum. (*G. L. O.*).—We are of the opinion that the Apples you send are local seedlings, and certainly they are of no value. (*C. M.*).—1, Lane's Prince Alfred; 2, Blenheim Pippin; 3, Lord Derby; 4, Beurré d'Amanlis; 5, Beurré d'Aremberg; 6, Beurré Capiaumont. (*N. P. D.*).—The Apple is Scarlet Nonpareil, and the Pear being unripe cannot be named. Read instructions above before sending again. (*V. F.*).—Alfriston. (*H. S.*).—Greenup's Pippin. (*P. J. P.*).—Irish Peach.

Names of Plants.—(*M. P.*).—1, Asplenium flaccidum; 2, Nephrolepis exaltata; 3, Osmunda regalis; 4, Adiantum farleyense; 5, Impatiens Hawkeri; 6, Allamanda Hendersoni. (*F. W.*).—Be good enough to read our instructions relative to florists' flowers, when you will find that we do not undertake to name them. (*T. H. C.*).—Pellæa rotundifolia, known also as Platyloma rotundifolia. (*K. W. G.*).—1, Lychnis dioica fl.-pl.; 2, Monarda didyma; 3, dead; 4, specimen insufficient; 5, Chrysanthemum maximum; 6, a Polygonum, species undeterminable without a description of the habit of the plant. (*C. N.*).—Owing to delay in the post and faulty packing your specimens were withered beyond recognition. We think they are distinct varieties, but whether they were admissible in a class for six hardy Ferns depends entirely on the wording of the schedule. (*J. G.*).—Montbretia Pottsi. We do not know the tree pruner to which you refer, but you can procure the Standard tree pruner from any seedsman. It is an excellent tool.

HER MAJESTY'S COMMISSIONERS AND THEIR REPORT.

"By a thorough knowledge of the laws of health, and by a strict regard to the working of these laws, good health can be made almost a certainty."

Appearances are deceptive, and it is not the pale and feeble alone who fall ready victims to disease and death. A wise doctor is not misled by outward show. He knows so much of his profession as to be certain that things are not always what they seem, and nothing will satisfy him but a minute and careful examination of his patient—his present condition, his earlier life, and even the habits and health of his progenitors and near relations. No fact is too minute, and no symptom, however obscure, can be passed over. Given all possible data to work on, he has a chance of arriving at the true state of his patient's health, and then is at liberty to prescribe the necessary remedies. Whether the remedies are applied or not, he has done his duty; and should the patient have reliance on the skill of his doctor, and a mind eager and willing to follow out the rules of

life thus laid down, there is every hope of a cure being effected, if the case be not already desperate.

It is of no use working in the dark, and accepting and using every nostrum prescribed by anxious friend or fussy busybody. It is only repeating an old tale to speak of the fearful depression which has of late years fallen on our English agricultural community—a depression that has stolen on us so gradually and so surely that at times we are nigh overwhelmed by its density.

That there have been times of trial and bad prices occurring at different periods we all knew, and we, hoping against hope, trusted that this heavy cloud would in due time pass away, and that things would regain their normal prosperity. As promotion cometh neither from the East nor the West, so hope begins to seem as far distant; indeed, so distant that it is hope no longer.

It was in the year 1893 that the Royal Commission appointed to inquire into the causes of agricultural depression began to sit; it is in July, 1897, that their report appears. There has been no undue haste, and we think they have treated the matter exhaustively. We are not quite sure whether they as a body are fully alive to the awful struggle it has been to many a tenant farmer to keep his head above water the last few years. The landlord seems to get the greater share of their pity; perhaps we are looking at their deliberations with a jaundiced eye.

As to the main causes of the trouble we agree—the falling markets and the need of thorough readjustment of rents. How to stay the fall in prices is more than anyone dare say. We might offer a suggestion, but possibly our suggestion might not be taken in good part by our readers. In many parts and on many estates there has been great abatement (permanent) of rent, but some landlords appear yet incapable of grasping the fact that bread cannot be got out of a stone, and that from a commercial point of view rents and the value of produce must be somewhere approximate.

Bearing in mind the fact that prices of grain have fallen over 40 per cent. during the last twenty years, and that beef has declined from 24 to 40 per cent., mutton from 20 to 30 per cent., wool 50 per cent., dairy produce 30 per cent., and Potatoes from 20 to 30, with Hops at an unprofitable price, the reduction in the rent of land must be something very material to meet the exigencies of the case. The fact that we now only grow about 25 per cent. of the Wheat we need proves that somewhere and somebody can grow that Wheat much more cheaply than we. At one time we felt safe if we had good Barley crops. Now the market is flooded with the produce of Eastern Europe, which quite knocks our prices on the head. In the same manner our Oats have to give place to Maize, so that we have literally nothing that will aid us to stem the flowing tide of misfortune.

The only people who appear to have made a living profit of late years are those whose holdings are suitable for the cultivation of dairy produce, fruit, and greengrocery, and who are close upon their markets—*i.e.*, near large towns, thickly populated districts, and the mining villages.

There is one thing in favour of small holdings—viz., the lessening of the labour bill. The farmer and his family do all the work, do it better, but at a lower price than hired labour. Well, we suppose if they are willing to be losers it is their own look out; but in a properly drawn balance-sheet we cannot see where the advantage comes in, it appears rather a case of robbing Peter to pay Paul. Whether any of us really understand the true meaning of bimetallism is an open question; yet a majority of the Commissioners agree that one of the steps back to prosperity will be the adoption of bimetallism in England. They ground their assertion on the fact that while agricultural depression is so wide spread throughout the countries of the world, the only two countries that are free have respectively, one a silver and the other a paper currency.

The heavy charges of the railways and the preference given in price in favour of foreign produce has been, and still is, a serious blow in the face to the English farmer. Legislature here seems powerless to step in to our aid, although there is great room for some radical change. The labour bill cannot well be touched with any safety; poor tilling means poor crops, and it is very false economy to deny the land proper attention. As to the sale of manures and feeding stuffs, well, this matter is practically in the hands of the farmers themselves. That it was not so some years ago we are the first to admit; but every farmer now knows the advantage of buying these commodities as per analysis.

The farmer wants a freer hand, too, as regards the management of his holding; in many cases he is treated more like a child or a person who is suspected of evil deeds. He is risking his capital, practically his all, and yet he is supposed to need the most stringent of agreements. That the burdens on the land are ever increasing we know sadly to our cost, and the present relief is but a flea-bite compared with our needs.

Unless something is done to attract the best class of farmers to the land, the chances are that the occupiers will be men totally unsuited to the pursuit of agriculture—men who have adopted this calling merely as a pleasant change from town life, and who, though they may have the capital, yet need the necessary skill to apply it in the best possible manner.

WORK ON THE HOME FARM.

When we were saving a fine crop of splendid Clover and hay in June and early July, we did not realise to the full the true value of it, but we know it now. For the past three weeks both horses and milk cows have been practically dependant on the haystack, for pastures have been dreadfully bare, and it is a marvel where the animals get a bite.

The rain of the 8th August, though not heavy, is now beginning to bear fruit, and the more recent heavier fall will assist the growth of herbage of which we are sorely in need. The weather now is of a very forcing nature. We hope after a good rain we may again have sunshine, for grass grown without it is of little value, as we found last autumn.

A large portion of the grain crops are now safely in the stackyard. Wheat is nearly all in, the principal crop left out being Barley. Rain in moderate quantity would still do the Barley much good. We have ourselves found the outside of the stook, which had been exposed to a few showers, much superior in quality to the inside which had been kept absolutely dry. Of course our last year's experience makes us dread the recurrence of such a disastrously wet time; but, nothing venture nothing have, and we are giving a part of our Barley the chance of a bath or two before stacking. There will most likely be an increase in the yield, apart from the quality.

Rain has kept Potatoes growing, and may be in time for the latest kinds. For second earlies it will do more harm than good, and these sorts would be better sent to market at once before second growth takes place.

Crops promise to be light all round, Giants and Up to Date, especially the latter, being the varieties that promise the best. New kinds are always promising, but it is seldom one finds the promise so well fulfilled as in the case of the Potato Up to Date.

We hear of thrashings of Wheat, and they are fairly satisfactory. The yield per acre will vary very much from 2½ to 6 qrs., but it is uniformly heavy proportionately to the straw.

REMARKS.

22nd.—Generally fine and sunny, but heavy showers between 3 and 4 P.M.

23rd.—Generally overcast, but sunny intervals.

24th.—Fair early; almost continuous rain or drizzle from 9.30 A.M. to 1 P.M., and heavy rain at 0.30 P.M.; fair after with occasional sunshine and spots of rain. Halo and parhelion at 6 P.M.

25th.—Generally overcast, with frequent thunder between 10 A.M. and 2 P.M., almost continuous rain from noon to 4 P.M., heavy at 0.10 P.M. with a little hail and two flashes of lightning. A little sun about 10 A.M. and after 3.30 P.M.

26th.—Generally sunny early; fair day; steady rain from 6 P.M. to 9 P.M., and rain at 11.15 P.M.

27th.—Bright sunshine generally, but cloudy for an hour or two at midday.

28th.—Bright early and much sun in morning, but a smart shower at 9 A.M.; drizzly afternoon; sunny evening.

A very showery week, but with much bright sunshine. Temperature very equable, but slightly below the average.—G. J. SYMONS.

DECORATIVE WORK.

THE question of decorating, under some of its diverse forms, is one that is always with us. At all seasons of the year one or other phase of this work enters into the lives and duty of most gardeners. Church festivals and public functions provide the chief examples on the one hand; on the other, and nearer home, all sorts and conditions of decorating, from that pertaining to the gay and festive scenes of social gatherings to the solemn and sad last duties paid to poor humanity. It has become an established custom to use the innocent forms which the kindly Mother Nature bestows on man, who finds that "For his gayer hours she has a voice of gladness, and a smile and eloquence of beauty;" and that "She glides into his darker musings with a mild and gentle sympathy that steals away their sharpness ere he is aware."

So much has been said from time to time upon the different forms of our subject by those eminently capable of treating of it; so much has been seen by most of us in the shape of work which, whether participated in or not, must to the observant mind have its correlative educational value, that at first sight the subject may be viewed as one upon which nothing remains to be said or to be shown worthy of occupying further space. This conclusion, hypothetically arrived at, would veto the subject as being exhausted, which, I venture to think, is as far from being the case as is any other of the great branches which spring from the ever-spreading tree of knowledge we fain would climb.

In a life's experience one has seen many examples of this kind of work, which may be termed good, bad, and indifferent, and in the same comparative degree we may see them still. Such being the case, as well as the subject in its comprehensive form being of more or less importance to most gardeners, it is purposed here to make a general review, as well as to propound some simple rules to form collectively outlines for beginners. As this, probably, will carry us beyond the limits of one paper the brief explanatory introduction appears necessary.

Those errors which are noticeable in one phase of our subject generally apply to all. These are over-elaboration; incongruity from the employment of

unsuitable foliage with certain flowers; a puerile effect from the introduction of too much variety; a disregard of working in harmony with architectural outline on the larger scale; and, generally, a want of forethought, which commences the work with the vaguest anticipation of results, and too often falls short of the desired effect.

Apropos of the latter may be mentioned the case of a worthy man and a good gardener, who was bidden to prepare his decorations for a marriage in high life. The time was ample in which to do it, and his cultural skill as a gardener left nothing to be desired in that direction, quantity and quality being conspicuous when, prior to the eventful day, all was transported to the village church. All the munitions of war (or of peace) having been so plentifully—nay, even lavishly—provided, one would reasonably suppose that victory lay in his own hands; but a confusion, perhaps paucity, of ideas of decorative art prevailed, which was evidenced at the start by "My Lady," whose anxiety had led her to inspect the initiatory stage, and ask for particulars respecting the more prominent parts, eliciting the reply, "I don't know myself what will be put there yet." And so the work proceeded, with endless shifting and re-shifting, doing and undoing, worry and confusion. Good effects close at hand were lost in the distance; and the elaboration of petty details, well enough for draping a greenhouse stage or furnishing a dinner table, were lost in the "dim religious light." Probably no man ever worked harder than our friend the head gardener, or received so few compliments for his pains.

Again, here is another sketch from life—a gardener's life; of one who bitterly complained of torments he endured over floral decorations in the mansion. The daily filling of the vases was a daily source of vexation, increasing up to that stage where patience was exhausted, and the last complaint hurried him out into the grounds to cut rough sprays of hardy flowering shrubs haphazard, with the remark, "That will settle the matter and settle me." He really thought he was to receive his *coup de grâce* by dismissal when the "mistress" sent for him to say, "B——, I am delighted with the vases, they look so light and natural; always do them like that;" and he did, losing in one accidental hit all the stiffness and constraint which had tied his hand till late in life. Similar instances of playing at cross purposes are somewhat common, and although some of the happiest effects have been, like many inventions and discoveries, the result of pure accident, which in no wise minimises their value, few decorators can afford to work upon lines so desultory.

For the benefit of young gardeners it may be well to inquire into the essentials which compose a good decorator. In the first place our subject is too elastic to be confined within any hard-and-fast lines, at the same time there are ethics of harmony and design which may not be disregarded. The eye and hand which have been conjointly trained in but the simple elements of geometrical drawing, with some knowledge of harmony in colours, will seldom lead the inventive faculties astray in this direction. For work on the largest scale our ideas should be as broad and as bold, one might even dare to say as noble, as those which have produced some stately pile we may be called upon to adorn. Work of this magnitude will, we may allow, be required but rarely at the hands of a gardener; church festival decorations being usually co-operative work, the several sections of it are usually undertaken by parochial volunteers; but whether a gardener is called upon or not to perform, to direct, or to advise upon such matters, it ought to be well within the scope of his intelligence to be able to do so; and not only able to advise, but from the very nature of his work and observation he should be better qualified to do it than anyone else.

In the main these sentiments will, perhaps, be endorsed by our liberal-minded readers, and in that expectation one may go so far as to say that it is essentially necessary that the eye should be trained at a glance to take in the chief outlines in order to form a ready and accurate plan. The critical eye will always seek for error, and, moreover, dwell upon it to the detriment of otherwise good work; in fact, one note of discord is sufficient to mar the harmony of the whole piece.

What could have prompted one decorator to spoil some really good work by hanging surplus wreathing swing fashion across a noble Gothic window, which had been beautifully outlined with the same greenery in conformity with its requirements, it is not easy to imagine, unless it proceeded from a weakness which could not let well alone. He could not stop when he had finished. Trivial as this may appear, it is a very common fault, and not less a fault that it springs from the best of motives. Much good work is spoiled by over-elaboration, particularly in dinner-table decoration, by those who have the greatest wealth of material at their command. A study of each form and phase of floral decorative art may worthily, I think, if briefly, engage our attention; hence the indulgence of further space is asked for.—

DECORA.

(To be continued.)

HARDY FLOWER NOTES.

LIKE all other occupations, gardening, even if followed for pleasure alone, brings with it its disappointments. Things do not always go smoothly; something happens to upset our calculations or expectations, and we are, as a matter of course, disposed to look upon the gloomy side of life. At these times we might do worse than become followers of Mark Tapley, and seek to find enjoyment even from the misfortunes of the day. Now and again we feel the need of a double inspiration of the spirit of that philosophy, and it is perhaps never more needed than when bad weather brings ruin to our hopes and mars or destroys our favourite flowers.

Such a time has come as these lines are written. Rain, not in showers, but in torrents, batters down the flowers and defaces or utterly ruins their beauty. What though the Sunflowers shine as gold through the driving rain! others there are which look weary of the element they at other times long for. The Gladiolus would fain have less now that it has reared its spike clad with beauty among the other flowers. The Sweet Peas "winged for flight," as Keats says, look as if they longed to fly to sunnier lands where their soft or gay-tinted blooms would enjoy a brighter time. The autumnal Roses look draggled and forlorn as they struggle against the storm, and other flowers are in no better plight. But this talk is profitless, and hardly in keeping with the Tapleian philosophy. Let us then see the flowers of the time through glass of brighter hue.

Much of the garden's attraction comes now from the Composites—from the Helianthuses, the Heleniums, Inulas, Coreopsis, and allied flowers, with the chastening coloured Asters. We must admit that the annuals, less enduring so far as regards duration of life, are priceless at this time, as are Dahlias, Gladioli, and other half-hardy flowers. The Cannas themselves are delightful in many gardens, with their handsome leaves and brilliant flowers. Let us not despise any of these. Let us draw from their ranks some to grow beside and associate with the perennials, which are the main subject of these notes. Others who make a special study of these half-hardy and annual plants can better tell of their respective merits than I. To them the duty of telling of these flowers in detail must be left, but it is surely permissible to speak favourably of them in general terms here. This said, we may turn once more to the perennial flowers which are, and must ever be, our principal topic.

Among these yellow-flowering composite flowers there are some with stiff and ungraceful habit, or with heavy, lumpy blooms. Fine flowers do not always go with graceful foliage, any more than are talent and beauty always combined in individuals of the human race. There are, however, among the Coreopsis some plants combining elegant foliage and pretty, if not handsome, flowers. None of these is prettier or more elegant than Coreopsis verticillata, a comparatively old plant, conspicuously absent from many gardens.

My first acquaintance with it was made a good many years ago at a flower show held at Carnforth, in Lancashire, where it was exhibited in a class for herbaceous plants. I was struck with its grace as shown, and this admiration was heightened when it was seen in the border. Some woodcuts give a very imperfect idea of its habit when it has formed a good-sized plant, and would give anyone a poor impression of its merits. It is vaguely defined as coming from the "United States" and has been in cultivation for nearly 120 years. The bright, golden yellow flowers are very pleasing, and from being held erect on their wiry stems are all the more effective. Much of the charm of the plant is undeniably due to the leaves. These are in whorls, and are very finely divided, so as to give them a very light and attractive appearance. It grows from 1 to 2½ feet high. C. tennifolia is a synonym. C. verticillata likes a light soil, with a fair supply of moisture in summer. In some gardens it appears to die out occasionally, but this seems to be only in exceptional cases, and it is difficult to suggest a cause for this, as it is quite hardy in even colder districts.

The Platycodons are justly general favourites with all. Their beautiful flowers are appreciated when fully open, and they are likewise admired when their buds are nearly ready to open, their peculiar, inflated appearance being the origin of the popular name of "Balloon Flower." There seems little conflict of opinion as to the respective merits of P. grandiflorum and its variety Mariesi: the latter, by a general consensus, being admitted to be of more perfect beauty than the taller typical form. P. g. Mariesi album is very beautiful also, and its greater novelty will in all likelihood lead to its rapid introduction into gardens now that it can be procured at a low price.

I do not think it is generally known that there are not only a white form of P. grandiflorum, but also some others seldom offered in nurserymen's catalogues. These are more expensive, but some may like to know of the existence of these forms, and what they are. There are semi-double blue and semi-double white varieties; also single, pale blue, and single striped plants. Such fine autumn flowering plants as the Platycodons deserve and require more attention than has been given them by many in the past. Once established, they should be let alone, and removed as seldom as possible.

Now that September has begun to run its course, the rock garden has lost much of its colour. Heaths, Autumn Crocuses, Campanulas, and some others yet help to keep up the interest so far as regards flowering plants; but the days of its greatest beauty are past for the year. Still some flowers of bright colour recognise the influence of the sun, cooler though it is, and spread their petals when it appears through the gloom. Among these are yet a few of the Oxalises, a class of plants but rarely grown on account of their reputed tenderness. One would not like to hazard the statement that this want of hardiness is not too common among the plants of the genus. Among them, however, we find a few which may be called hardy in gardens in mild localities where a light, well-drained soil, and a sunny, warm position can be found.

One of these is Oxalis lasiopetala, the Hairy-petalled Oxalis. This has what have been called deep rose-coloured flowers, with perhaps a tinge of that purple so prevalent in the genus. This tint of purple is a defect with many of the flowers; but we must take them as they are, and find counterbalancing advantages if we can. Another defect is that the flowers are sun-lovers, and hardly condescend to open except when the sun shines. It is a failing from one point of view, but only helps to give strength to the pleasure we have in brighter weather. These flowers are produced in what is called by botanists a cyme, and the flowers are thus more effective than if produced singly. The leaves are radical, are raised on rather long petioles, and have obcordate, deeply notched leaflets; the root is tuberous. O. lasiopetala comes from Monte Video and Buenos Ayres. It is a wise precaution to give it a slight covering in winter.

Those—and their number is fast increasing—who find in Alpine gardening a pleasant hobby might do a service to many others by experimenting with other members of a genus little known in the outdoor garden, and not sufficiently appreciated by those who make perennial flowers their study and care.—S. Arnott.

DECADENCE IN TRAINING WALL FRUITS.

Your correspondent "H. D." (page 213) writes well on the "decadence of wall fruit culture;" but I wonder how old he is. I am old enough to believe two things—1, that fruit, generally speaking, is "cultivated," so far as size and quality are concerned, as well as ever it was, though there are exceptions; but (2) that the training of trees against walls has, as a rule, degenerated into a procedure of huddling and shuffling. In innumerable instances this is pitiable to see; and not in all of them, or in half the cases, is the true cause want of time or the pressure of other duties, but lack of interest, zeal, or knowledge, or perhaps of a little of all combined.

Gardeners, as a body, worked quite as hard a generation and more ago as they do now, and if not harder, certainly more hours. The best of them, who took real pride in their work, would no more let their wall trees suffer by want of timely attention than they would allow the Grape crops to be spoiled through negligence in thinning; and they would as soon devote two hours before 6 A.M. or the same time after 6 P.M. to one duty as the other, and this without whining and grumbling, or preaching about "slavery." It was not regarded in that light at all, but the work was done cheerfully by head men and under, for the credit of the garden and of themselves.

What, however, it may be asked, has all this to do with "H. D.'s" age? Nothing; but something else has, and this something he furnishes himself in the following words:—"I yield to no one in my admiration of a well-balanced, fan-shaped tree, in which every angle is a correct one; but they are expensive objects of beauty, which gardeners can scarcely afford to grow in these utilitarian days, for much labour is needed to keep them in the best condition."

In my wonder as to how old "H. D." is, it is not to be presumed that he is thought to be a mere boy, or anything of that kind. The excellence of his article as a whole forbids any such presumption; but while admitting he has had good experience in some, and perhaps many, things, I am all the same convinced that he is not old enough to know what he is talking about when he proclaims a well-trained tree, be it fan, horizontal, or any other shape, as "too 'expensive' to keep in the best condition." He has fallen a victim to, by becoming a believer in, a popular fallacy.

What he has written in the sentence cited cannot have been founded on experience. If he had ever had really well trained trees with "every angle correct" to manage he would not have written such nonsense. All the old masters of the art of training wall trees know perfectly well that those which they prized as approaching their standard of excellence as "objects of beauty" ("H. D.") cost less, and a good deal less, in keeping them in the desired condition than do those which are managed (?) in the rushing and crushing higgledy-piggledy fashion, miscalled training, now so prevalent in many gardens.

Then comes in the blessed word "utilitarian." It seems to have become quite fashionable of late. One purpose it serves is that of a great garden umbrella, under which "modern" men who do not (cannot) do what the ancients did, take shelter. It is certainly easier than working—in hot weather. "We have to make the most of everything in these days," say the moderns. "We have even to sell all we can, and make all we can—quite different, you know, from what it used to be." Used to be! How do they know the customs of the time before they were in "button clothes?" If they had worked in gardens half a century ago they would have found something else to do than going a tripping.

Though it was not proclaimed from the house-tops, there was plenty of selling in those far-past days. There was as much of it in a ducal garden, and another of a knight of the shire, in which the writer served, as could be got out of them by the most strenuous exertions; and there was—and here is the point—as much money made from the splendidly trained wall trees as I venture to say "H. D." has ever obtained, or ever will obtain, from an equal area of surface, which trees are made to cover on, what I call, the anyhow plan, but which he euphemistically terms the "less methodical" system.

By the "anyhow plan" you rush the trees into bearing a year or two sooner, crowd them with fruit which is more stone than luscious pulp, more core and kernel than flesh, thus deceiving the public and shortening the lives of the trees, then thinking yourselves clever enough to be knighted like Sir Joseph Paxton. Do not be vain; do not harbour the false notion that bad training (unsightly trees) means good crops, and good training (handsome trees) means bad crops. The idea is too stupid to be discussed.

If a man, be he of the ancient or modern school, cannot grow crops of fruit quite as valuable from well-trained as from ill-trained trees he does not know his business, and ought not to pose as a gardener, but step into his right place as a not over-intelligent labourer. He may do good and honourable service there, also, perhaps, make a "bit of money" and be happy.

I have been watching the tone of the moderns for some time in silence—publicly at least, but not privately, for there I call them wildings—until I can stand it no longer, and at last, like the old hunter, have broken loose for a dash after the hounds, as if the cub-hunting season had come round again. In full cry are you? Well, I think I can stand the music.—Melton.

"H. D.," at the close of his paper on this subject in the *Journal of Horticulture* (page 213), asks for a sort of vote or expression of opinion as to the reasons why this phase of gardening should have gone back, as it undoubtedly has gone back, in garden management during the last ten or twenty years. There is no question in my mind that the two causes given by "H. D." are the strongest influences in the matter. First, reduced labour, partly caused by the depression in agriculture and in everything pertaining to land, plus increased society expenditure, which contribute their quota to the expenses of an establishment, and when economy has to be enforced it is usually, more's the pity, the garden department which feels it first and heaviest.

Second, fashion in table and house decoration, which has gone up by leaps and bounds for some time now, making an excessive demand on the labour that is left, and causing the strength of the establishment to go towards productions for decoration both indoors and out, so that the fruit and vegetable departments have to make shift with what they can get. The other work *must* be done, the latter as it can; thus it comes to pass that the garden walls, which were one time the pride of the gardener by reason of their order of training and fruitful health, are now left untrimmed till late in the year, and that which has to be done is done in a hurried and slipshod manner, distressing to a quiet, orderly mind, and this with insect visitations, which cannot be attended to at the proper time, soon reduce the fruitfulness of the trees.

There is another cause, though, which was unknown in the higher class gardens years back, but which is increasing slowly but surely every year, and that is, the commercial spirit which has entered into nearly all private establishments, great and small. When a nobleman opens an emporium in one of the principal streets in London, and sends to it the best products of the garden, the farm, the dairy of his estate, and makes no secret of it, and he only one of many who trade in one way or other, we may well say that market gardening has become the trade of the aristocracy. When this shop supply has to be kept up day by day, and week by week the year through, then the gardening at that establishment has to go on quick, up-to-date lines. More orchards of the new, attractive, and quick bearing Apples, Pears, Plums, and Cherries are planted, larger breadths of land laid down for the bush fruits, and more and larger areas of the garden, and sometimes farm land, devoted to Strawberries. Everything is arranged to bring in the "nimble ninepence" and the "slow shilling" crops, including the wall trees, have to get what attention they can.

This is enough to make the hair stand on end of the old gardener who has been accustomed to take things calmly, to have time for everything, and to distribute what he had of overplus to those on the estate, who would be benefited thereby. Oh, yes! "the old order changeth." Now all is push and "go," and jobs that used to be done steadily by the workman are very often pushed on, and the workman is unceremoniously told that, "It'll do," and sent on to the *next* job. Well, gardeners who are wise will recognise this state of things, and adapt themselves to them as well as they can, and even we old fogies must bend to circumstances, and adapt ourselves to them. It is no use moaning and lamenting over past days. We may groan over our neglected wall trees, which have been our hobby for many and many a year, and sigh over the decadence of wall tree fruit tree growing, but *cui bono*?

To my mind these are the strongly operating causes, and I send them in as my vote or opinion to account for the decadence of wall fruit tree culture.—An Old Provincial.

LIFTING AND POTTING CALLAS.

The Callas (Arum Lilies) which have been planted out in the open ground should now be lifted and potted, so that the plants may have time to become established before the advent of frosty nights demands that the shelter of glass be afforded them. The size of the pot the plants require will depend on their strength, and whether a number are growing together, or only a single crown. Fairly strong and vigorous single plants may be placed in 7 or 8-inch pots. Two plants, if strong and well furnished with roots, cannot be easily accommodated in a less size than a 9-inch pot, unless the roots are freely reduced to fit a smaller pot. Larger specimens may be made by employing clumps with an increased number of plants, or placing smaller clumps together to fill the pot. Provided the plants were given good material when planted in the open in early summer, they may be lifted with the soil adhering to the roots, only sufficient of the latter being cut off, along with the slicing of the soil, to make the ball fit the pots.

Some check may be afforded to the rapid growth of the plants previous to lifting by running a sharp spade round them about a week in advance of potting. They may need the roots still further reducing at the time of lifting, but the check will be less sudden and severe.

It is an advantage to have the roots and soil moist, though not in a wet mortary state. To insure a moist condition water copiously the day before lifting. This, however, would be unnecessary if the operation is carried out on the first dry day after a good downfall of rain.

The pots required ought to be clean, moderately drained, and in readiness to be occupied as the plants are lifted and prepared. Over the drainage of crocks consisting of two large pieces and a few smaller, place a layer of flaky manure, scattering upon that a dusting of soot. Very little prepared compost will be required, but some may be conveniently at hand to fill up spaces when potting. Loam, with one-fourth decayed manure and a little sand, forms a suitable mixture.

When each plant is lifted with the spade chop round it to the approximate size of the pot and cut off the base to the necessary depth. Carry out the final reduction of the roots with a sharp table knife, reducing the ball so that it may be sunk into the pot just about level with the rim. Then, by gently jarring the pot on firm but yielding ground, the whole may be sunk low enough to afford room below the rim for the supply of water. Any spaces left may be filled in with compost.

After potting stand the plants in the shade, giving a good soaking of water. Syringe freely every dry day, and when established bring out the plants to a sunny and open position, where they can remain until the period of housing for the winter.—E. D. S.

HOME-MADE WINES.

(*Concluded from page* 214.)

Raisin Wine.

When we consider that raisins are merely Grapes deprived of their water by evaporation in the sun, we have no difficulty in seeing how well they are adapted for wine making. The best for this purpose are Valencias, and, if these cannot be had, the next best are Malagas. Before using them the raisins must all be separated from the stalks.

To make an 18-gallon cask of wine, 20 gallons of must has to be provided, and 6 lbs. of the picked raisins must be added to each gallon of water, so that it will require 120 lbs. of raisins to make the 20 gallons. After the raisins are stripped from their stalks they are to be put into an infusing cask, with 20 gallons of soft water, heated to the temperature of 90°, and then the whole is to be well stirred. The stirring and bruising of the fruit in the infusing cask is to be done three times a day for eighteen days, and a sample of the must is to be taken out morning and evening for the purpose of being examined by the saccharometer, and the gravity noted. As soon as the saccharometer indicates a gravity of 80, the must is to be drained off from the infusing cask and strained through a sieve into the fermenting tub, the fruit being well pressed with the hands and thrown into another vessel ready to receive it. The 20 gallons of must, which will now indicate a gravity of 80 or 90, is to be brought up to the standard of 135 by the addition of sugar, which will be a little over $1\frac{1}{4}$ lb. for each gallon, and also 6 ozs. of argol.

As the making of this wine takes place in the winter, the temperature of the apartment where it is conducted should not be less than 55°. The must is to be well stirred every morning, and if all goes well the gravity will probably fall in the course of a week to between 90 and 100, but this will greatly depend on the warmth of the weather. When the must has attained this gravity, it is to be put into casks for the final fermentation, and the casks ought to be washed out with boiling water, and the must put in while they are warm. If fermentation through this has been checked and the must remains in a dormant state, put in three table-spoonfuls of good thick brewers' yeast, mixed with a quart of the must, heated to a temperature of 85°. The heated must and yeast are then to be put in a vessel capable of containing two quarts, as it will expand. In about an hour after this expansion will take place, and be accompanied by an early fermentation. It is then to be put into the 18-gallon cask, which is to be kept full to the bunghole so long as the vinous fermentation lasts, and afterwards bunged up.

To Clarify Wine.

If the wine be good and rich but not bright it may be fined by any of the following methods:—

Milk Fining.—This is only used for white wine, as it would injure the colour of red wine. The quantity to be used is 1 pint of skimmed milk to every 5 or 6 gallons of wine. Pour upon the milk some of the wine drawn from the cask, mix it well by stirring with a stick, then pour it into the cask; rouse it up well with a stick, without disturbing any dregs there may be at the bottom. In three or four days it will be fine, and must be bottled off as soon as possible. Wine is always spoiled by leaving it long in contact with the fining, whatever the fining may consist of. Milk fining is preferred when the wine is harsh and has acquired a dark stain, which milk removes.

Isinglass Fining.—This fining is preferable to milk for general use, and is applicable to red as well as white wines. The best method to pursue is as follows:—For a hogshead of wine take a quart of warm water in a large jug, and put to it 1 oz. of isinglass broken small; add to this 1 pint of white wine if for general use, or some of that which is to be fined; stir the whole up three or four times before the water is cold; let it remain two or three hours, or if not dissolved, two or three days—the time is immaterial, but it should be quite cold and quite dissolved before going further—now add a pint more wine; stir the whole up well, and strain it through fine linen. This is wine fining, as sold by the makers in wine countries, and 1 pint of it is sufficient for 15 gallons of wine.

According to the size of your cask, take so many pints of this fining; mix more wine with it, which will perhaps occasion a floeculent deposit; this must not be lost, but the whole tubbed through the hair or wire sieve, or, still better, milk strainer. The fining will be ready now to put into the cask; and the reason of diluting it first is, that if you put it in too strong it coagulates immediately and falls down in lumps, rather than in the fine particles which are required. Stir the whole up well after the diluted fining is poured in, bung the cask down tightly, let it stand till the wine is fine, which will be from three or four days to a week. Bottle off without disturbing the lees or sediment.

Egg Fining.—For English home-made wines and for the red wines of France, the white of an egg is generally employed. The white of seven eggs is sufficient for a hogshead of wine, and to employ

them it is only necessary to beat them up in a quart or two of the wine; then put the mixture into the cask, and rouse or stir it up well with a stick. Egg fining is generally longer in settling than isinglass, and to fine a hogshead occupies from two to three weeks. If it is not intended to bottle the wine, it must, after fining, be racked into a clean cask in all cases.

Sulphuring Wines.

To prevent wine from fermenting too long, and thereby becoming too much attenuated, and also to prevent a second fermentation, by which the wine would be converted into vinegar, it is necessary to what is termed "sulphur" them. This is done by burning a sulphur match in the cask, after a portion of the wine has been withdrawn to give room for the match to be burned. The match is a strip of linen or cotton cloth 6 to 7 inches long, 1½ to 2 inches wide, dipped in melted sulphur. These matches are attached to the bung, and when set on fire are introduced into the cask and the bunghole is closed. By burning the sulphur sulphurous acid gas is generated, and this acting on the wine arrests the acetous fermentation.

ESCALLONIA LANGLEYENSIS.

Many of the Escallonias are cultivated in gardens, and are, as a rule, very highly appreciated. The majority of them are exceedingly beautiful, and do thoroughly well on walls, or even in the open borders in sheltered places, or by the seaside, where they thrive splendidly. As the well-known forms are so popular, the hybrid depicted in the illustration (fig. 33), and which was shown at the Drill Hall in June by Messrs. J. Veitch & Sons, Ltd., will most certainly be welcomed. E. langleyensis resulted from a cross between E. macrantha and E. Phillipiana, and, as may be seen, partakes somewhat of both parents. The flowers are produced in clusters on the branchlets of the strong growths, and are, of course, much more numerous towards the top than they are at the bottom. The colour of the flowers on first opening is bright rose, but they pale slightly with age. An award of merit was granted by the Floral Committee.

A NORTHERN TOUR.

A few days' relaxation from the ordinary routine of labour, with a change of air, scenery and company, is oftentimes productive of physical, moral, and mental good. Perhaps few would anticipate a beneficial change from the Garden Isle to the busy and smoky counties of Yorkshire and Lancashire, but in a "tyke" there is an in-bred affection for old friends and old scenes. Brief notes of my tour may interest if not instruct a few of your readers.

I left the Garden Isle the last day in July, staying the night in London and proceeding to Bradford from King's Cross on the following day. The harvesting operations round Hatfield and Hitchin seemed to be in advance of the Isle of Wight, which I considered was mainly due to the former places being minus the sea breezes which are constantly experienced in the latter place. Many of the stations on the route were made gay and cheering by hanging baskets which contained flowering and foliage plants in variety. What a great scope there is for development in this direction. May we hope that the various railway companies will still further encourage their officials to make not only the approaches to the stations but the platforms and waiting rooms gay with plants and flowers?

Shortly after leaving Doncaster a change came over the scene; huge chimneys towered high above the masses of houses here and there, being only separated by a few miles of country. The hedges were replaced by walls, and instead of hamlets there were busy and thriving towns, the landscape being adorned with pit shafts, pit hills, and coal waggons. Bradford was my first stopping place. This town has lost one of its greatest benefactors in the late Sir Isaac Holden, Bart., of Oakworth House. After a night's repose several town gardens and the parks were inspected. Lund Park is on the west of the town in a thriving and populous district. The situation is rather exposed, but since my visit two years ago several alterations have been made by Mr. J. Slater, the able gardener, which will prove beneficial. The carpet bedding is very appropriate to the season, and is well done; whilst the mixed bedding of flowering and foliage plants is effective. The inhabitants of the district take great interest in the park, and are highly satisfied with its present condition. Devonshire Park is to the north of the town. It is in excellent condition under the direction of Mr. Bainbridge, and affords a welcome place of rest. Victoria Park to the eastward is a large expanse of land where huge trees relieve its monotony and afford shelter not only from passing storms but also from the sun's powerful rays in the hot days of summer. It is admirably suited for galas and fêtes.

Town gardens are by no means numerous, no doubt largely due to the difficulties which have to be encountered. R. Edmondson, Esq., Acres House, is an enthusiastic floriculturist, and spares no pains or expense in doing things thoroughly. Mr. W. Shaw, his gardener, shows excellent results, considering the manifold difficulties under which he labours. J. B. Summerscales, Esq., Rockfield, is another gentleman passionately fond of horticulture, but has to labour under unenviable climatic conditions. Under glass plants are looking exceedingly well; Tomato crops excellent; Grapes are fine, bunches and berries large, well shaped and a good colour. Mr. J. Sugden, the gardener in charge, is thoroughly at home in the various branches of gardening.

On Saturday, August 7th, I paid my first visit to Tong Agricultural and Horticultural Society's Show, and to Tong Hall, the residence of Sir Robert Tempest, Bart. The old-fashioned mansion is situated in a lovely and well-wooded park of over 300 acres. The horticultural department is under the superintendence of Mr. R. C. Turner; the condition of the kitchen, fruit, and flower gardens, the vineries, Peach, and plant houses marking him as a man of exceptional abilities. The Chrysanthemums are very fine indeed, whilst the Tomatoes are cropping freely and show no signs of disease.

In the evening I was privileged to join the members of the Bradford Paxton Society in their visit to Bowling Park, which is one of the far-

Fig. 33.—Escallonia langleyensis.

famed Bradford parks, and is ably managed by Mr. J. Spencer. Considering the park has been made out of pit-hills and is so situated as to have more than its share of wind and smoke, it certainly reflects great credit to the gardener and his staff. There were several fine plants of Centranthus alba, which had an imposing effect. Looking down on the flower garden with its many beds filled with flowering and foliage plants, judiciously arranged, as the sun was sinking in the west, one saw an effectively beautiful picture.

From August 9th to 12th a few profitable days were spent in Darwen and district. Since my last visit to this progressive town two parks and a technical school, with reading room and free library, have sprung into existence. Bold Venture Park I consider, for its size, one of the most picturesque and natural I have ever seen. The undulations, deep ravines, and miniature waterfalls, relieved by the greensward, with here and there beds planted with the choicest of trees and shrubs most suitable to the district, give it an effect that words cannot describe. Its close proximity to the centre of the town renders it an invaluable acquisition, whilst at the rear only two or three fields separate from it the famed Darwen Moors, which rise to a great height above the sea level, affording a magnificent view for miles around. Whitehall Park is esteemed by the inhabitants of the far end of the town; it is not only well laid out, but ably managed.

Woodlands, the residence of W. B. Huntington, Esq., J.P., is picturesquely situated in a well wooded estate. The conservatory, stoves, greenhouses, vineries, and Peach houses are very extensive, and are under the superintendence of Mr. Wm. Neale, the head gardener. Astley Bank, the residence of C. P. Huntington, Esq., J.P., is another local place noted for horticulture. Mr. C. Grey is an adept in most branches of gardening.

One of the most instructive things to me round Darwen was to see the interest the amateurs and cottagers took in the things they were growing for exhibition. These men are nothing if not enthusiastic; fighting as they have to do against soil and climate, the results they obtain are surprising. A visit to Blackburn Park was a treat not to be missed, whilst my Lancashire tour was brought to a close with a hurried glance into Milnshaw Park, Accrington.

On the 12th I returned to the broad-acred shire, with a few days to take leave of my friends ere proceeding to my home in the Garden Isle. What one sees and hears on these short visits would fill columns. One gardener is a strong advocate for hotbeds; another thinks the periodical lifting of Peach trees and root-pruning, with the addition of new material, is a necessary operation to obtain the best results; whilst a third dissents from this altogether, believing that feeding with liquid manure and top-dressing is quite sufficient. And so I might go on, giving the opinions of men I met whilst on my northern tour.—S. Heaton.

IS GRAPE GROWING DEPRECIATING?

Doubtless we are very reticent in these go-ahead times to admit that in any phase of the gentle art we are in reality not going forward, but losing ground. It is, however, questionable whether such is not the case, and though "Traveller," on page 170, ventured on dangerous ground, there appears to be a good deal in what he says that it is difficult to refute. His arguments will doubtless be met from different standpoints. In the first place, there are men who are always ready to uphold anything that favours the good old days, and are unwilling to admit the effectiveness of any modern development. "Traveller's" notes will serve as a balm to their spirits, and if I mistake not his sentiments will be fully re-echoed in the mind of many a gardener of the old school. Secondly, there are the young bloods—gardeners trained in a more recent school, who are apt to look disdainfully on the methods of the "old fossils," as your correspondent terms them, and think that nothing can be good if it is not original. It is somewhat surprising if this section of the craft do not pour the vials of their wrath on the offending head of "Traveller," or set him down as being some ancient fogey, who stands up for old times simply because they were the days before he was bowled out by some youngster, who perhaps had once upon a time crocked pots for him.

Thirdly, there is another section of readers, men who have no particular prejudice either way, but are ready to look at any argument fairly and squarely, and then attack or defend it as their convictions direct. There is a distinct tone of sadness running through the article on page 170, and one gathers the idea that the writer is fully decided that the whole thing is going to the dogs as fast as it can, and in a few years the time-honoured craft will be nothing more than a name. Fear not, "Traveller;" the ground gained is considerably wider than that which is lost, and if as the Editor suggested, you went to Shrewsbury, let us hope that you returned home a re-assured man, with some feelings of satisfaction that after all everything relative to gardening is not in a state of decay.

In agreeing with the sentiments respecting the decadence of Grape-growing to some extent, perhaps I may be referred to the great provincial exhibition as an undeniable proof of the high standard of excellence still maintained in the cultivation of this popular fruit. It is true that magnificent Grapes are always seen at Shrewsbury, and is it surprising when we consider the magnitude of the show, the wealth of prize money, and the all-important fact that it takes place at the very best time of the year for the exhibition of Grapes? The Grapes at Shrewsbury are an exception, and allowing their excellence by no means does away with the contention that we rarely see the quality that was exhibited years ago. Even the Shrewsbury prizewinners may be counted on the fingers, and while we worthily sing their praises we must remember that some of the chief of them belong to the same school as Mr. Henderson, who did great things at the time to which your correspondent refers.

Leaving Shrewsbury out of the question, let us turn to the earlier shows, when to get white Grapes an amber colour and black Grapes like Sloes is an art worthy of the best of gardeners. "Traveller" speaks of Hamburghs weighing nearly 20 lbs., doubtless exhibited at a summer show; I refer to Hamburghs that were subjected to hard forcing through the treacherous early months of the year, and exhibited in May and early June in a high state of excellence, that nowadays is rarely seen.

There will doubtless be those among the readers of these lines who remember the splendid examples of Grape-growing skill that used to be staged at the Whitsuntide shows at Manchester. There I have seen perfect bunches of Hamburghs weighing from 2 to 3 lbs., and similar bunches of Foster's Seedling and Buckland Sweetwater, with large highly coloured berries, in every way fit for table. Consider that the Vines which bear Grapes at that time of the year have to be sharply forced, and the most consummate skill of the gardener must be brought into play to bring them to anything like perfection. The question asked is, Are such Grapes shown now at the early shows? I append also my answer—an emphatic No.

Again, turn to the great R.H.S. show in the Temple Gardens. In most respects its excellence and magnitude have extended wonderfully, and visitors attend in increasing numbers yearly with the expectation of seeing the highest results of gardening skill. There is indeed much to admire, but what of the Grapes? Neither at the last nor the preceding show was there anything worthy of more than passing recognition. It might be that the Society's award is not considered sufficient by gardeners to repay them for the expense and labour incurred in showing at the Temple; but, on the other hand, gardeners or their employers exhibit collections of vegetables, fruit trees in pots, and groups of plants. No, the argument is not strong enough, so it must be that first-class Grapes at Temple Show time are scarce so scarce, that a meritorious exhibit rarely now appears on the tables.

The Crystal Palace Fruit Show is rapidly drawing near, and "Traveller," with others who are interested, will have an opportunity of noting whether there is or not real ground for fear. At a great show devoted entirely to fruit, and held directly under the auspices of the premier Society, we certainly *ought* to see the best examples of Grapes that our gardeners can produce. Yet is it so? According to last year's standard a negative answer can only be given. With a few exceptions the bunches were loose, and the berries lacked the colour and finish that all good Grape growers love to see. In the black Grapes there was a redness easily noticeable, and with the white ones there was a tinge of green instead of the golden amber that should characterise them in September. I hope this year will see an improvement, as the Show, in the deterioration of the Grape section, will lose one of its brightest features.

At the Drill Hall meetings, too, we get almost everything in the way of fruit, flowers, and vegetables, but rarely any Grapes. The solitary instance I can call to mind was the exhibit last year which came from Chiswick Gardens. Gardeners show collections of Apples and other fruit, including Melons galore, and why not Grapes? The only answer seems to be because they have not got them. Drill Hall meetings in magnitude and variety have grown amazingly during recent years; yet no one ever seems to look for Grapes, and would doubtless be surprised to find any there. Surely this ought not to be if the art is not declining.

I have recollections of gardeners who would have proudly exhibited their Grapes before the Fruit Committee, and been satisfied with the award it gave. No such feeling appears to exist in these days. If these defects are so apparent in the greatest centres of horticulture, what must it be at shows of lesser importance? But perhaps, and let us hope there are, shining lights in the Grape-growing world who as yet are only glimmering in a little local hemisphere. Like your correspondent, I claim to be by no means of a pessimistic turn of mind, yet when I compare the Grapes of to-day with those of not many years ago I agree with him that so far as this important branch is concerned gardening is decaying.—A Kentish Man.

Improving Vines.

The paper that first drew attention to the state of our Navy could certainly have caused no more astonishment than have "Traveller's" Notes on the above subject (page 170). We have been accustomed to read of the progress of gardening during the Victorian era, and of classes being set apart at some of our great shows to demonstrate the advance in horticulture, and then to find we are so far behind our forefathers in the cultivation of the king of fruits comes as a revelation. That "Traveller" was not struck with anything in the Grape classes, except it was an absence of finish in so many of the bunches, I have no doubt, but I feel that there are many beside myself who think that if the glass and money were forthcoming there are still men who can turn out noble bunches, and so uphold the reputation of British horticulturists.

"Traveller" has pointed out why Roses are not shown so well as formerly, but his inference cannot be applied to gardeners. Why is the high-class cultivator being crowded out? Why is the smart (with his tongue) up-to-date young man taking his place? Cannot employers afford to pay a good cultivator? This is the only reason I can assign for any decadence in gardening.

I will close this, my first contribution, by a few cultural notes. If the Grapes are unsatisfactory (and this is the time of year to judge), endeavour to ascertain the cause. If spurs or rods are too crowded cut the weaker out. If there is a doubt about the roots being in an unsatisfactory state lift them. What is the best compost to use, and how the border should be made would be a good text for a cultivator who has proved the material. We are not allowed turf, yet we have lifted most of our Vines. What we have used with the most satisfactory results some may like to know.

We get a good accumulation of rubbish, and this we burn, as described by Mr. Iggulden (page 115). We commenced the work of lifting in November, taking three Vines at a time. We removed all the soil from among the roots, and as this was thrown out the burnt earth was mixed with it, this frequently being red hot. This with mortar rubbish was freely used, and after all had been well mixed and stood, while the drainage was seen to, till in a condition suitable for potting, the soil was returned and trodden as firmly as possible until nearing the surface. The roots were then laid in and the soil pressed moderately firm about them. How much burnt material may safely and advantageously be used in making up a Vine border I cannot say, but I do think that if a great deal more were used with the turf that is so frequently recommended, and that put together firmly, we should improve our Grapes.

We may not get canes so quickly or stout, but what we have last longer and finish the crops better than those grown in decaying turves. The manure our Vines get is from earth closets, with liquid manure from the home farm. They are watered with weak liquid through the summer, and during wet weather, when the liquid is weakened by autumn rains, we throw it on as brought from the farm.—S. B. O.

[A very good "first contribution." We like to hear from gardeners who can describe clearly how they succeed under difficulties, and "S. B. O." may treat his pen to a little exercise again. Perhaps the "Traveller" had not had a good day among his clients, and sought solace in publicity.]

SIXTY YEARS' PROGRESS IN HORTICULTURE.

(*Concluded from page* 215).

FLOWERS.

I HAVE given precedence to fruits and vegetables because they form two of the staple foods of our country, and are considered necessities of life. But when I come to treat on plants and flowers that have been introduced or raised during her Majesty's reign, I confess I hardly know where to commence, and shall find it more difficult to stop. The old brick flues with which I have had some sad experience have been superseded by the clean, sweet, easily controlled hot-water systems. The tubular, the Trentham, or Cornish, and saddle boilers have taken the place of the brick furnaces, so that we have been able to nurse and bring to perfection the many choice exotics that have come to us from all parts of the globe.

One has only to look in at the cottage windows to see the difference in the window plants from those of olden days. One rarely sees the old Candle Cactus, the Onion plant, and the old red-veined Begonia sanguinea that used to be in nearly every cottage window in the country forty years ago. I do not wish to disparage these old plants. There was a charm about them that made them a part and parcel of the family. The owners were so much occupied in those days in the fields and otherwise that they had not time to attend to the more tender plants even if they were procurable. The old plants would bear to be left for a time without water or other attention, hence Cactuses and other succulents were largely grown to what they are now. Some of the old people would always have their Balsams for the summer months, sowing the seed on a given date in spring, growing the plant in an old teapot or basin, and top-dressing with tea leaves just before coming into flower. Now the cultivation of flowers is getting more understood, and the very great variety to hand is filtering through to the humblest cottager. The formation of cottage garden shows enables him to exhibit his produce, and encourages him to renewed energy for another year, giving him healthy occupation in his spare time, and beautifying and brightening his home.

Then, too, the greater facilities for travelling have enabled collectors to search for and quickly import many valuable additions to our stoves, greenhouses, and flower gardens during the past forty years. If we look at the choice exotics that are grown for the beauty of their foliage or flowers, or in the wonderful development of the orchidaceous family by introductions from their native clime or by the scientific hybridising by our own eminent men, or at the extraordinary transformation our flower gardens have undergone, or the types of florist flowers or the several occupants of the conservatories as they follow on in their successive seasons, we can get but a slight conception of the marvellous changes of the past sixty years.

True there were enthusiasts then, but their devotion was centred in a limited number of plants. Chief of the florists' flower was the Tulip, for which we hear and read of such fabulous prices being paid. It was part of my duty when a lad serving under a grand old florist, whose memory I shall ever revere, Mr. Adam Spary of Ventnor, to look after a collection of Tulips. We had the bizarres, byblœmens, and selfs planted on a particular date and taken up on a certain day. I had to unroll or roll up the calico covering that was over the wooden framework of the bed in which they grew at every outburst of sunshine after they began to show colour; and although not old enough then to enter into the spirit of the thing, in after years I could understand better the delight ovinced by the grand old florist when he saw a certain variety breaking eut into its natural colouring, or a seedling showing some great improvement on its parents. Auriculas, Polyanthuses, Carnations, and Pansies were the chief florists' flowers handled and exhibited by specialists at their various shows, which were held chiefly in the Midland and Northern counties. I must confess to a partiality for the florists' Auricula, having grown a collection and taken prizes at the National Auricula Society, that now holds two exhibitions yearly, one in London and one in the Midlands. Dahlias, Balsams, and Cockscombs also I should mention. Persian Ranunculus used to be grown and shown with the Tulip, and later Show Pelargoniums and Fuchsias were the chief plants in which the gardens in private establishments used to try to excel in those days. Camellias were in great force and highly appreciated; Humea elegans is another graceful flowering plant that was in much favour, and is still grown by many.

The mention of Zonal Pelargoniums revives the whole history of the bedding-out panic, of which I could write pages. In my younger days I used to follow dear old Donald Beaton in all his writings in the *Journal of Horticulture*, and when he hybridised and sent us out those beautiful Nosegays Stella, Amy Hogg, Helen Lindsay, Christine, and Trentham Rose, they gave a fillip to the bedding-out system that was just then getting a hold on the public taste. My early impressions of bedding-out plants are associated with Tom Thumb and Little David "Geraniums;" the variegated varieties Bijou and Brilliant, mixed with Cuphea platycentra, Alonsoa Warscewiczi, and Purple King Verbenas. Then came the golden variegated "Geraniums" Golden Chain, a rather weak grower; and later, Crystal Palace Gem, Flower of the Day, Flower of Spring, and British Flag, followed by Madame Vaucher, a good white and François Desbois, one of the first of the salmon-shaded varieties. Compare these with the wealth of very fine varieties that we have now, and realise, if you can, what we owe to earnest workers in hybridisation. The double Zonals caused a sensation when they made their appearance about thirty years ago. We are indebted to our continental friends for these, and I think Mons. Lemoine gave us the first one. About this time Mr. Peter Greive raised and sent out Mrs. Pollock, the first tricolor "Geranium," which became all the rage. Soon after we had Sunset, supposed to have been an improvement on the older variety; and many cultivators turned their attention to this class, and the trade did a brisk business, Messrs. Smith & Son, Dulwich, and Rollisson and Son, Tooting, two old firms, making a speciality of them. Messrs. Rollisson guarded them as securely as possible, and it was quite a favour to get a glimpse of their propagating house, or the show house wherein they were grown. I remember a bull dog being tied up near the houses to protect them during the night. Two fine varieties, Star of India and Moonstone, at a guinea each were being distributed at the time of one of my visits there about twenty-eight years ago.

Following these came the bronze Zonals, Mr. John Wills, gardener to Sir Philip Egerton, Oulton Park, making a hit in that direction. Beauty of Oulton and Black Douglas were two of his best in this section. He also raised a dwarf bedding variety with small golden foliage, named Robert Fish. Mr. Wills told me the story of how it received that name, which was something as follows:—When his friend Mr. Robert Fish, a well-known horticulturist, came to visit him and inspect his new seedlings, he told him that he would name either of them after himself if he would make his choice, thinking one of the many seedlings of the bronze section would be chosen, instead of which the choice fell on a dwarf distinct variety with plain yellow foliage. Years revealed the wisdom of his choice, as Robert Fish was well adapted for ribbon and carpet bedding, and was grown by thousands when some of the others were forgotten.

Plants with self-coloured foliage were in great demand about this time for ribbon and parterre bedding. Coleus Verschaffelti, Iresine Herbsti, and Perilla nankinensis with dark foliage, Centaurea candidissima and elegantissima of the light foliage being much sought after, and very widely grown. Carpet bedding followed, and then all kinds of dwarf plants with plain foliage were much used, the various Echeverias, Sempervivum, and other succulents harmonising well with the bright-coloured foliage of tho Alternantheras and other plants. Thence came the more general use of foliage plants, which developed into subtropical gardening, Mr. W. Robinson being a strong advocate of this, *versus* the bedding out or the parterre style. At the present time the prevailing fashion in the public parks and other gardens is a combination of all three. Fine-foliage and tall-flowering plants are utilised, to break the formality and add to the effect of the arrangement.

Begonias belong to the past twenty-five years of the reign. Who could have thought when Messrs. Veitch & Sons of Chelsea sent out Chelsoni and Veitchi, hybrids, I believe, from boliviensis and fuchsioides, that they were the forerunners of such excellent varieties as John Laing and others have produced?

Of Chrysanthemums I have not time to say much, not because I have no wish, but they have been talked about and written of so much lately, that it would be only repetition if I were to enter into particulars. They are, without doubt, one of the flowers of the reign, and the introduction of the Japanese has made them one of the most popular flowers of the day. English-raised varieties have superseded the continental ones to a large extent, and I am proud to say we are indebted to the Isle of Wight for some of them.

Many very beautiful flowering shrubs, hardy foliage plants, as well as tropical ones, creepers to adorn our houses, such as Ampelopsis Veitchi and the beautiful varieties of Clematis; flowering bulbous plants, including the splendid golden-rayed Lily of Japan, with many more, have all been introduced during the latter half of the period under notice, and have added to the attraction and adornment of our homes and gardens.

The Rose is our national emblem, and ought not to have had last place. The old Cabbage Rose, the Moss, the Provence, the Boursault, and Noisette varieties have all been hybridised and superseded by the Hybrid Perpetuals. The beautiful Tea scented varieties from which we have the Hybrid Teas, are grand improvements on the old varieties, and will ever keep up the regard and esteem for our national flower.—(*Paper read by* Mr. C. ORCHARD, *Bembridge, at the Ventnor Institute, on August 7th.*)

SECURING FRUIT.

A VERY proper and concise answer to Mr. W. J. Murphy (page 194) would be to ask him kindly to practise those directions given many times in this paper. To read his letter of appeal for guidance in fruit tree culture, while he himself gives the very reasons, I believe, for his trees' barrenness, is most disheartening to those who have written and taught so patiently and well. Mr. Murphy states not whether his trees are on walls or free in the open. By his own admission neither soil, varieties, nor management—which appears limited to pruning and insect destruction—are to blame. Without further aberration, the cause of the evil leads us to settle directly upon that "unfortunate spell of frost" which was not warded off. Two hundred years ago pomologists took little heed of their trees' roots, but were careful to protect the blossom often by laborious means. They had walls with projecting copes; used bass nets and draw curtains, and even troubled themselves when building fruit walls to insert tiles or flat pieces of wood between the bricks or stones at distances over the face of the wall. These protectors protruded 1½ or 2 inches, and sloped slightly downwards.

Such simple, yet laborious, contrivances saved blossoms from many degrees of frost. We do not trouble ourselves nowadays with such methods; no, we give our trees too little care. Destruction comes in spring by the condensed night vapours falling lightly on the exposed blooms, dewing them over, and under a clear sky the continued radiation, or process of

cooling, causes such coldness that the dew freezes, and a whole year's work may be blasted. These "frosts" fall perpendicularly, and thus we need only to thrust a dried Spruce or Yew bough below the coping, or have glass protectors sloping out a foot from the wall top, so as to shield all beneath it. It would be inconvenient for Mr. Murphy, perhaps, to have mats for his trees, but surely he might contrive to fix an overhanging ledge, or the means for securing boughs, canvas, or old sheets of any suitable material.

To protect standard or espalier trees, a framework, over which some light material can be stretched, is the only true and safe method ; the standard trees placed perpendicularly, a long pole through the middle part of the tree, and have others, plus covering, to be in readiness on emergency. Poles, or slender bars placed X fashion over the trellis, with a horizontal bar running in line with, and resting on, their small top angle, securing these from collapse, afford a frame for covering, and keep the material free from the blossom, which might be spoilt unless the protected cover be held off.

You cannot get your fruit without less trouble, unless you start and plant cordons along the edge of your walks, forming a series of arches with them by bending down the points. Splendid results have been obtained from this simple plan. Now as to watering. It is essential that the buds be "plumped up" before the season's vigour ceases. Water and mulch so as to secure stoutness in wood and bud, yet reckon to have the wood properly ripened. A dry autumn is a desideratum. Mr. W. J. Murphy had blossoms this year, therefore last year cannot be blamed much. Proper nourishment with protection this spring would have secured "fruits in their season." Read "H. D.'s" article on "Watering Wall Trees," page 139, August 12th. Have no rank roots to your trees ; let them be fibrous. Keep the branches well apart, and with spur-bearing trees attend to pinching ; thin-out young shoots early on other trees. Never allow insects or disease to harm your trees. Water, mulch, and protect when needed ; then and not till then, you will have done your duty.—J. H. D.

THE FUNGI OF THE WREKIN.

The Wrekin, which is denominated the oldest mountain in England, and which is such a conspicuous headland as seen from the railway running through Wellington in Shropshire, near which town it is situated, is a famous place for fungi, the woods which surround its base and sides literally teeming with them, especially during the months of September and October. Botanists and ordinary visitors alike who visit the famous Salopian hill in the course of their rambles around cannot fail to be impressed with what is well termed the mycological flora of the neighbourhood.

We all know now, or ought to at least, that in addition to the ordinary field Mushroom which finds such general favour, there are great numbers besides which afford capital eating. The woods around the Wrekin are in most seasons most prolific in the production, both specifically and numerically, of these interesting, and in many cases extremely curious, forms of vegetable life.

Many species of Polypori are to be found growing out of the trunks of the Larch and Pine trees and their roots, or on the patches where the wood has been burnt for charcoal, such as P. squamosus, P. rufescens, P. perennis, P. chionens, the beautiful P. frondosus, whilst in many places the edible Hydnum repandum abounds, with its awl shaped spines on its lower surface. The very curious H. gelantinosum has also been found at times in old saw pits and in similar places. The large red copper Agarie, Amanita muscaria, and A. phalloides are unfortunately rather common. They are both poisonous, hence it will be seen the selection of fungi is no easy matter for an amateur, who, if not sure of what he is gathering, had better inquire from one better versed in the knowledge than himself, and to avert unconscious disaster. Singular to say Amanita rubescens, another variety of the same species, is perfectly wholesome.

Flammella carbonaria, as might be inferred from its name, is found where there is charcoal. Trichiloma imbricatus, T. rutilans, T. saponaceus, and T. terrens are everywhere to be seen. Chitocyte giganteus, a favourite edible, grows in rings in many places with several other species of the same genus. Lactarius deliciosus is found mainly under Fir trees, and, as its name implies, is good eating. The Boleti are numerous. Amongst them B. luteus, B. flavus, B. edulis, B. elegans, B. luridus, and B. scaber, a pretty fair variety.

The edible Cantherellus cibarius is also met with in some spots, but is by no means common. Near the top amidst the moss we come across Hygrophorus Houghtoni (named after the Rev. W. Houghton, F.L.S., who has written much about the district of the Wrekin), the lovely golden yellow Peziza aurantiaca is also to be seen. The curious but nasty smelling Stinkhorn (Phallus impudicus) is rather common, whilst the equally curious but not so repellant in odour Cynophallus caninus, which is generally held to be a rare kind, grows in the grass amongst the Larch trees and the Oaks in the large fields bordering on the next side of the mountain.

Several other species of Hygrophori are also to be found in the same locality, amongst them H. coccineus, H. pratensis, H. psittacinus, H. conicus, H. calyptræformis, H. puniceus ; whilst in the adjoining woods we meet with H. corsus, with its strong goat-like odour, by no means pleasant. These woods are a rare hunting ground for the Mushroom hunter. It is impossible to enumerate a tithe of the species that are there to be found, but the above selection will serve to show that the woods of the Wrekin are full of rich treasures for the botanist and others.—Wm. Norman Brown.

KALOSANTHES COCCINEA.

Taking into consideration all the good qualities possessed by this beautiful, sweet-scented greenhouse plant, it is surprising that it is not more frequently met with in a condition creditable to the cultivator. Under good cultivation its habit is close and compact, producing a profusion of bright flowers which contrast well with the deep green foliage. Although it is of too stiff a character to be useful for cutting (an indispensable quality with many), still, when it is grouped with other plants in the conservatory, or associated with Ferns and foliage plants for house decoration, it is generally admired.

The ease with which it is propagated, the short time required to grow it to a serviceable size, and its comparative immunity from the attacks of insects, ought to commend it to everyone.

I will give a few hints on the culture of this beautiful old-fashioned plant, and first as to propagation. This is too often recommended to be done in August. It roots freely at any season, but I think the best time is from the middle of March to the middle of May, or as soon as convenient after the bloom is visible in the tips of the shoots. Select shoots that have failed to bloom, and take them off close to the old wood. Trim a few of the bottom leaves off and insert them singly into thumb pots, or five in a large 60. Use a mixture of fibry loam and peat, or loam and leaf soil, with a good dash of sharp sand. Water well, and place in a warm moist atmosphere for about three weeks, when they will be rooted sufficiently to be removed to cooler quarters—a shelf near the glass in a greenhouse, where they may remain till they fill their pots with roots.

About the beginning of June the young plants should be shifted into a size larger pots, the single plants into 4½-inch, and those with five cuttings into 5-inch pots, using the same compost, but in a rougher state, and with less sand in it. Drain the pots well, and place a little moss over the crocks to keep them clear of soil. The plants may then be placed in a close frame till they have well rooted into the fresh soil, then gradually harden. After this our practice is to plunge them out in coal ashes, giving them exactly the same treatment as winter-flowering Pelargoniums. Those, however, who have a very heavy rainfall to contend with should have them in frames, or a sash placed over them to throw off the heavy showers, exposing fully in dry weather. As soon as required each plant should have a small stick to it, to keep it upright and prevent its being broken.

Most writers on the Kalosanthes recommend the young shoots to be pinched. I have proved this to be quite unnecessary ; in fact, it tends to make a rather stiff plant, more formal than it would be if left to its natural growth. Allow the plants that have been potted singly to grow without stopping. Those intended for larger plants, the four plants round the outside of the pot, may be stopped early in July, but train the centre plant to a stick without stopping. They will thus produce free, natural pyramids, clothed with flowers to the edge of the pots.

Excepting that they should be carefully watered, but little attention is necessary till they are housed for the winter at the end of September or beginning of October. They should then be placed on shelves near the glass, where they will be cool and have plenty of air. They will continue growing, and should by no means be stinted for water, as is advised by some writers. Of course, as the days shorten less water is required as a natural consequence, but this does not mean that the soil is to be allowed to get dry, for the roots are very active during the autumn months, and should be encouraged. Soon after the turn of the year—say the middle of January—the plants should be shifted into their flowering pots. The single plants may be potted into 5 or 6-inch pots, and the others into 7 or 8-inch. The plants make rapid progress during February and March. They should be regularly attended to with water, and when the pots are well filled with roots, should be assisted with a little weak liquid manure twice a week.

By the end of the latter month the plants will be showing blooms, when they must be staked and tied. Stakes should be used as sparingly as possible. One or two to each plant is generally sufficient, the other shoots being looped together for support, something after the style of tying Phœnocomas and hardwooded Heaths for exhibition. Keep the plants as close to the glass as possible till they come into bloom. They will be cooler and require less labour in watering if turned out into frames or cold pits early in May, from which they can be transferred to the conservatory as they come into bloom.

Old plants are generally considered useless as far as blooming the following season is concerned. One plant last year bloomed so freely that we had a difficulty in getting sufficient for this year's stock. I was thus induced to save a few old plants to furnish cuttings. These were allowed to become dry at the roots, cut hard back, and after giving the wounds time to heal to prevent bleeding were placed in a brisk heat. They were afterwards placed outdoors with the others and had the same treatment, except that they were shifted when they were housed for the winter into pots a size larger. These have furnished us with abundance of cuttings, and, more than we expected, a fair sprinkling of bloom.

The Kalosanthes is hardier than some of our bedding plants. Some of the above-mentioned plants were outdoors in the open till the 12th of November, and endured 3° of frost without showing the least signs of having been injured. It is, in fact, one of those plants that may very easily be "killed with kindness."

Market growers, who require flowering plants as quickly as possible, do not follow this mode of culture in every respect. Instead of rooting

the cuttings in small pots, and shifting them into larger ones as required, they insert them in the pots in which they are intended to bloom, and thus save the time necessary in repotting. The majority of the plants sent to market are only one year old.—G.

BEGONIAS AT YEOVIL.

"CAN you direct me to Mr. Davis's nursery?" I asked of a Yeovil rustic the other day, when a little uncertain as to which turning to take. "Do 'ee mean the ''Gonia' man, zur?" said he. "Yes," I replied. "Then," said my informant, "go down there, and jest up the hill, an' you'll see his place, an' they be purty vlowers, too, zur, he grows. Why zome be as big as zaacers, the zingles and ther dooble be loike girt cups opside doon, an' sich 'coolers.'" "Yes," I remarked, "I have seen them at the great shows, and now I am going to see them growing." I thanked my friend, and wended my way to the nursery.

It is Mr. Davis's fortune not only to be an inhabitant of a great country business town, but also to have his nursery situated beside a fine and much-frequented highway, so that large numbers of persons are attracted to the Begonia show, under glass and outside, so liberally furnished, and which can be seen from the road, or may be more closely seen by visiting the place, as it is freely open to inspection by all persons.

I was fortunate enough to find this energetic and highly intelligent Somersetshire florist at home, and in his company examined the huge stock of Begonias growing. A cursory inspection reveals the fact, absolutely undoubted, that the quality of the Yeovil strains, whether single or double, is equal in every respect to the best of the metropolitan or other provincial strains, if not in some respects better. This is due to the fact that Mr. Davis is a Begonia enthusiast, does his own fertilisation, intercrossing, and selecting; hence he not only knows what he wants, but works exactly to that end, and results amply justify that personal action; for whilst his strains have in colour a marvellous variety, the quality is indeed splendid.

With such superior excellence no wonder the title of "Yeovil" Begonias has become of world-wide knowledge, for Mr. Davis has customers all the world over, and the good Somerset town has gained through our florist friend some acceptable notoriety also. At this late period of the summer, although there were thousands of fine plants blooming in the houses, yet the chief centre of interest was found in the fine seedlings blooming in beds outdoors. The site of the nursery is on the north-eastern slope of a hill, and fully exposed in spring to very cold winds, that render growth rather late; and still farther, the exeessive dryness of the soil so long in the summer did not help growth either. But this now is fine indeed, almost luxuriant. None the less, it is not aimed to make the soil too rich. The same sites have to be utilised year after year, and have worked into them leaf soil or well-decayed manure; but still the object is to produce not the biggest, but the firmest and most perfectly matured tubers for storing in the winter and ordinary sale. Such tubers not only, if needed, give the best cuttings that endure, but also produce by far the best flowering plants.

Then ample evidence of the admirable capacity of the Begonia to withstand storms and bloom under adverse weather conditions, for but three days previous to my visit there had passed over the locality a fierce wind and rain storm, generally to fragile flowers and plants most destructive, but the Begonias seemed not only unharmed, but bore few evidences of injury. They were in flower and foliage superbly fresh and beautiful. It is difficult to say whether singles or doubles exhibit the greatest variety of colour. I noted in both white, lemon, yellow, orange, apricot, pink, carmine, cerise, salmon, scarlet, magenta, and crimson; indeed there seems to be every possible self hue found except the blue shades, and whilst Begonia growers would like to obtain these, I hardly share that wish. Then there are even of these mentioned so many diverse tints, and of edged, or flushed, or shaded flowers, others in great abundance. Without doubt the Begonia has given to us shades and combinations in colour no other flowers produce.

Whilst in the singles we see in all directions thick petals of fine rounded form associated with great size, we see in the doubles much departure from those crowded-petalled Hollyhock-like masses, more of the broad flat shell petal of the Camellia and Rose. To obtain these Mr. Davis has worked specially, realising that they present features that are so much to be admired. Pretty crumpled edges also are here and there reminding one of goffered frills, as once such popular wear, and this break will be worked upon doubtless with good results. Of course there are Picotee edged flowers, and some show broad margins of colour on white that lead to the impression a fine-margined strain may be ultimately produced.

It is worthy of note that single seedlings not only come very true to variety, but they never seem to diverge from the single character, except specially fertilised to that end. Doubles, on the other hand, do show in seedlings a small percentage of singles, as all who purchase seed know. Those who, rather than bother with uncertain seedlings, prefer to purchase a dozen or more of selected doubles or singles as now marked in the seed beds, not only get all of different colours, but all are true to form as desired. Seedling tubers the following year make fine pot plants, and once obtained may be grown on indefinitely. Mr. Davis has worked hard also to secure the best possible stocks of small-flowered, erect-blooming varieties of rich or striking colours for bedding, and these are so employed, thinly planted on some neutral coloured carpet, are singularly beautiful.—A. D.

Notes & Gleanings

WEATHER IN LONDON.—Though we have had two or three fine days during the past week a considerable amount of rain has fallen. This was particularly the case on Sunday, when it rained nearly the whole of the day. On Tuesday, again, there were heavy showers. Wednesday was fine.

—— PHOTOGRAPHS.—We inadvertently omitted to state that the excellent photographs sent to us last week of the Shrewsbury medals and presentation epergne were taken by Mr. W. W. Naunton, one of the Secretaries of the Shropshire Horticultural Society, who is an expert in such work. The photographs in the preceding issue were by Mr. Bartlett, Shrewsbury.

—— GARDENING APPOINTMENTS.—Mr. Richard Chubb has been appointed head gardener at Farmingwoods Hall, Thrapston, Northants. Mr. William Coomber, who had to relinquish the charge of Lilford Hall Gardens through the death of his employer, the late Lord Lilford, has been appointed gardener to Lord Grey de Wilton at Houghton Hall, Swaffham, Norfolk. Mr. David Johnston, for the past four years general foreman at Strathfieldsaye, has been appointed head gardener to H.R.H. Prince Hatzfeldt at Draycot Cerne, Chippenham, Wiltshire. Mr. G. Gurney, late head gardener to Mrs. Powell, Maesgwynne, Carmarthenshire, as head gardener to Viscount Raincliffe, Blankney Hall, Lincoln.

—— LILIUM AURATUM AT LOGAN HOUSE, WIGTONSHIRE.—Mrs. McDowall of Logan is an enthusiastic cultivator of Oriental Lilies. She is specially successful with Lilium auratum, which attains to an unusual height and strength. One of the finest specimens of this noble Lily I have ever seen is 7 feet 8 inches high, while the stem is fully 5 inches in circumference. The number of flowers, twenty-one, is by no means very unusual, but they are, on the other hand, of more than average size, being in most instances nearly 12 inches across. L. auratum rubro-vittatum is unfortunately not largely grown, as I am sure it would be found highly ornamental. I do not find it, however, so vigorous as its contemporaries, nor is it so floriferous.—DAVID R. WILLIAMSON.

—— GATHERING PERFUME FROM LIVING PLANTS.—It is said that a method of gathering the scent of flowers as the plant is growing has been discovered by a Captain Smee. He takes a glass funnel, and heats the thin end over a spirit lamp. He then draws out the stem to a fine point. This accomplished, the funnel is filled with ice and placed on a retort stand, the pointed end being placed in a small glass bottle, without touching it. After this, the stand and the funnel are placed in a greenhouse, among the flowers whose odours it is desired to collect. Gradually the vapour rises from the flowers, and in meeting the colder surface of the funnel condenses into drops on the outside of the glass. From the point of condensation it trickles down until it drops into the bottle. In a surprisingly short time a large amount of perfume is collected, and it is claimed that 90 per cent. of the contents of the bottle is perfume; the rest is water. Strange to say, this essence of the flower needs to be adulterated with spirits of wine, otherwise it would become sour and useless.

—— HERO OF LOCKINGE MELON.—Taking all points into consideration I question if this grand variety has yet been surpassed. The colour and netting are perfect when the fruit is well grown; the flavour too, is quite first rate, and I know of no variety which produces a heavier fruit in proportion to its size. At the present time I have a small house filled with plants of this well known Hero. The majority of the fruits have just completed the netting process, and a very pretty lot they are, none of them being large, but all must be deep fleshed, for they are heavy and solid, no hollow sound being given out when the fruit is tapped with the knuckles. They have been grown entirely in a rather light loam, weak liquid manure being occasionally given. Melons growing in a liberally manured compost often produced very large specimens, but as a rule they lack depth of flesh, and do not satisfy a critical judge, who tests them by trying their weight. And it is seldom, indeed, that these large fruits bear favourable comparison with smaller ones in point of flavour. One does not often meet with the true form of Hero of Lockinge now, for when more than one variety is grown in a house it is almost impossible to obtain seed true to name.—D. W.

—— Bulbs for the London Parks.—We are informed that for the ninth time Messrs. J. Carter & Co., High Holborn, have received the order to supply the whole of the bulbs required for the Royal Parks of London for next season's bloom. The firm has also again received a similar favour from the London County Council for the parks, gardens, and open spaces under its control.

—— Abstract of Climatological Observations at Driffield.—Mean temperature at 9 A.M. (corrected), 63·35°. Wet bulb, 58·79°. Mean maximum, 70·51° ; mean minimum, 50·27°. Highest, 81·2° on 5th ; lowest, 40·2° on 3rd. Mean of maxima and minima, 60·39°. Mean radiation temperature on grass, 44·71° ; lowest, 34° on 13th. Rainfall, 3·69 inches. Number of rainy days sixteen. Greatest amount on one day, 1·18 inch on 26th.—W. E. Lovel, *Observer, York Road, Driffield.*

—— August Weather at Worksop. — Mean temperature, 61·5°. Maximum in the screen 89·1°, on the 5th ; minimum in the screen 41·4°, on the 2nd ; minimum on the grass 35·2 , on the 2nd. Sunshine 201 hours, or 45 per cent. of the possible duration. Rainfall, 2·16 inches. Rain fell on nineteen days. Maximum fall, 0·61 on the 30th. Rainfall since January 1st, 15·52 inches. A warm month, with some very hot days in the first week ; maximum the highest since 1876 ; the latter part showery.—J. Mallender.

—— Weather in South Wales.—The following is a summary of the weather here for the past month :—Total rainfall 7·66 inches. Maximum 1 inch on the 7th. Number of days on which rain fell, twenty-two. Rain fell on each of the last sixteen days, with very little sunshine for the whole period. Average maximum temperature 71°, with a maximum of 102° on the 2nd. Average minimum 49°, with a minimum of 42° on the 24th. The prevailing wind for the month was S. and S.W. There were seven sunless days. A very hot sunny week at the commencement of the month, since which there have been very strong, and in most cases cold winds ; a heavy thunderstorm and hail on the 31st.—Wm. Mabbott, *Dowlais.*

—— The Weather Last Month.—August was very wet after the 17th, with frequent thunderstorms, and was also remarkable for the large amount of sunshine. The wind was in a southerly direction twenty days. The total rainfall was 4·51 inches ; this fell on nineteen days, and is 1·85 inch above the average for the month. The greatest daily fall was 1·10 inch on the 30th. Barometer (corrected and reduced) : highest, 30·250 inches on the 3rd at 9 A.M.; lowest, 29·439 inches on the 21st at 9 P.M. Thermometers : highest in the shade, 88° on the 5th ; lowest, 44° on the 26th ; mean of daily maxima, 70·93° ; mean of daily minima, 52·38°. Mean temperature of the month, 61·65° ; lowest on the grass, 41° on the 26th ; highest in the sun, 144° on the 4th. Mean of the earth at 3 feet, 60·45°. Total sunshine, 233 hours 10 minutes. There were no sunless days this month.—W. H. Divers, *Belvoir Castle Gardens, Grantham.*

—— Starch from Sweet Potatoes.—Although it has long been known that the Sweet Potato contains starch in considerable quantities, the question whether it can be made a profitable source for the manufacture of starch on a commercial scale has only recently been raised. Very interesting, therefore, is a bulletin from the South Carolina Agricultural Experiment Station at Clemson College, from which it appears that at least 22 per cent. of starch can be counted upon in most varieties of the Sweet Potato, while in some kinds the product ranges still higher. Counting the yield of Sweet Potatoes at from 200 to 300 bushels to the acre in South Carolina, which is moderate, since 500 bushels to the acre have occasionally been accomplished, it appears that the amount of starch yielded by an acre of Sweet Potatoes is much greater than the amount yielded by Wheat at twenty bushels to the acre. That is, an acre of Sweet Potatoes will yield four times as much starch as an acre of Wheat. The Sweet Potato even has, says a transatlantic contemporary, the advantage over the Irish Potato in this regard in the Southern States. Of course, this does not establish the fact that the Sweet Potato can be profitably raised as a starch producer. In the first place, a more thorough test of the quality of the starch and its fitness for sizing will have to be determined. Again, the value of the by-products is much smaller than the value of the by-products in the manufacture of starch from corn. Besides this, much must be learned about the cost of producing the Sweet Potato, the changes which may take place in storing it and the cost of manufacturing the starch. Nevertheless, the bulletin is an extremely interesting one, and it is full of suggestion as to the proper soils and fertilisers which the crop demands for its best development.

—— Sussex Rainfall in August.—The total rainfall at Hayward's Heath for the past month was 3·76 inches, being 1·48 inch above the average. The heaviest fall was 0·77 inch on the 8th. Rain fell on sixteen days. The maximum temperature was 88° on the 5th, the highest of the season ; the minimum, 46° on the 13th. Mean maximum, 75·05° ; mean minimum, 53·02°. Mean temperature, 64·03°, which is 3·49° above the average. It rained more or less every day since the 17th of the month. September 1st was extremely wet and stormy.—R. I.

—— Nymphæa lilacina. - This hybrid Water Lily of Marliac, which was imported a year or two ago, does not seem to have received the attention to which it is entitled, perhaps because it is still rarely seen in cultivation. Cut flowers, especially if a trifle old, as seen at exhibitions, give one a rather poor idea of the beauties of Water Lilies, which are seen at their best only in some quiet pool with a foil of crystal water. Unlike the well-known Nymphæa Laydekeri, which it resembles in colour, N. lilacina may be increased by division. Its leaves are similar to the former variety, but the petals are wider and more numerous, and it has a larger array of golden stamens. It is difficult to convey an idea of the exact differences between the two hybrids without an illustration which would show them clearly. As the flower of N. lilacina is also larger, and as bright in colour and apparently as free-flowering, it seems to me that, on the whole, it is an improvement on the older variety. N. Laydekeri, however, is a good reliable variety, even if after five years the old plant is no larger than at first planting, and has never shown a sign of increase. —J. N. Gerard (in "Garden and Forest.")

—— Railway Platform Gardening. — The flower gardens which skirt the various platforms on the Midland Railway are just now clothed in their gayest summer attire. In several places along the line there are marvellous displays of flowers ; in many instances the stationmasters have made elaborate arrangements ; the slopes and terraces are masses of floral beauty, and are highly creditable to the unwearied efforts of the cultivators. The flower-garden arrangements on the platforms at Matlock Bath and Belper were beautiful. It must be understood that these are busy stations. Beginning with the former, what is now the flower garden was formerly a rough, sloping bank, but now formed into a series of terraces one above the other. The lower terrace is raised above the ground level by a row of rough Derbyshire stones, specially adapted for the purpose, the interstices being filled in with masses of Arabis albida, which in the spring must be sheets of pure white flowers. The space beyond the Arabis was devoted to Nasturtiums, a dwarf and compact variety, and extremely floriferous. The next terrace is laid out in grass, with sixteen beds cut in the turf, and all kept exceedingly neat and in perfect order. The upper or third terrace was also formed with large rock stones, over which streamed in graceful festoons many coloured Nasturtiums, suspended in graceful luxuriance. Behind the Nasturtiums we noticed a bed of dwarf Roses. These had done duty "in the time of Roses," and promised a fine autumnal bloom. At Belper we have a series of terraces, but differently arranged to those at Matlock Bath. Beginning at the bottom the earth is held in position by large stones in every respect suitable for the purpose ; these are draped with large masses of Arabis albida, commonly called Snow on the Mountain, a useful spring-blooming plant, but would be still more effective if it were mixed with the blue Aubrietia—Aubrietia deltoidea. The terrace is divided into a number of flower beds, which have for dividing lines rock stones, which are in harmony with all the other arrangements. The beds along the terrace are filled in with a great diversity of plants, all beautiful and effective. These included bedding Pansies, Petunias, Stocks, Asters, and white and blue Lobelia. In the centre of the terrace there is a design formed of Thrift (Armeria vulgaris) in large letters—Success to our Town. This was very striking, and would be more especially when the Armeria was in full bloom. The next terrace displayed a considerable amount of thought and ingenuity. It was broader in the centre, and tapered a little towards each end. Besides the Stocks, Asters, Petunias, Pinks, and Nasturtiums, which were all masses of glowing beauty, there were several designs in limestone. In the centre there was the name of the town in large letters formed with limestone. Above this a mass of Stonecrop. Higher up was the Queen's crown, in memory of her Majesty's Diamond Jubilee, and also passing through the town on her way to Sheffield. Many shrubs have been planted on the embankment near the station, which in a few years will give it the appearance of a large pleasure garden. It must be highly gratifying to the company to find their stations and platforms clothed with so much richness and beauty ; while the stationmasters must be amply rewarded in knowing their labours are so thoroughly enjoyed by an appreciative public.—R. W. L. (in "Derby Reporter.")

—— JOURNAL OF THE ROYAL HORTICULTURAL SOCIETY.—The volume of this publication which has just come to hand is an extremely interesting one, and contains much valuable information. It opens with a list of the Victoria medallists, and comprises in addition valuable papers on Microscopic Gardening, by Professor Marshall Ward; Bud Transference, and its Effects on Fruit, by the Rev. Gordon Salmon; Artificial Manures, and their Bearing upon Horticultural Practice, by Mr. J. J. Willis; Winter and Spring Bedding in Flower Gardens, by Mr. Alexander Dean; Diseases of Plants, by Mr. George Massee; Physiology of Pitcher Plants, by Professor Sydney H. Vines; and Storing and Preserving of Fruit, by Mr. Joseph Cheal, beside other information of considerable value. The price to non-Fellows of the Royal Horticultural Society is 5s., and it may be obtained from the offices of the R.H.S., 117, Victoria Street, Westminster, S.W.

—— MOSS ROSE LEGEND.—There is a very pretty German tradition, not generally known, which accounts in the following manner for the existence of the Moss Rose. The legend is to the effect that once upon a time an angel, having a mission of love to suffering humanity, came down on earth. He was much grieved at all the sin and misery he saw, and at all the evil things he heard. Being tired, he sought a place wherein to rest, but as it fared with his Master, so it fared with him—there was no room for him, and no one would give him shelter. At last he lay down under the shade of a Rose, and slept till the rising sun awoke him. Before winging his flight heavenward he addressed the Rose, and said that as it had given him that shelter which man denied, it should receive an endearing token of his power and love. And so, leaf by leaf, and twig by twig, the soft green moss grew around the stem, and there it is, to-day, a cradle in which the new-born Rose may lie, a proof, as the angel said, of God's power and love.

—— ISLE OF WIGHT.—The monthly meeting of the Isle of Wight Horticultural Improvement Association was held at Newport on Saturday last. Dr. J. Groves, B.A., J.P., presided over a large attendance of members. Mr. J. Merritt, gardener to H.R.H. Princess Beatrice, read a thoroughly practical paper on the "Cultivation of Violets," which was highly appreciated. It was resolved to have an excursion to Swanmore Park during the month. It was also decided not to have a fruit exhibition this year. Messrs. J. Cheal & Sons, Crawley, offered the Association a championship trophy if they had an exhibition next year. The Association certificates for cultural merit were presented to Messrs. Sheath, Goble, Jacobs, Richards, Kine, Matthews, Went, Lipscombe, Geddes, and Philpot for their meritorious exhibits at the various Island shows held during the summer. The tables contained some excellent productions. Cultural certificates were awarded Mr. G. Williams for a stand of Cactus Dahlias and two dishes of Plums, Victoria and Bon Bouche; Mr. W. Matthews for Dahlias, and Mr. C. Martin for seedling Gloxinias and Begonias. Mr. C. Martin also staged a collection of Melons, a seedling, a cross between Royal Favourite and Blenheim Orange, a fine dish of Brussels Sprouts, and a collection of Nectarine Peach. Mr. J. Barkham staged a fine Melon of Sutton's A1, weighing about 6 lbs. Mr. J. Cheal had a fine collection of seedling Cactus Dahlias. Mr. Merritt staged fine plants of Violets Princess Beatrice and Princess of Wales. Eleven new members were elected.

—— WOLVERHAMPTON GARDENERS' CLUB.—The annual outing of the above Club took place on August 26th, when forty-four members and friends visited Chester and Eaton Hall Gardens. The party left Wolverhampton at 7.40 A.M. in two saloons of the L. and N.W. Railway, arriving at Chester about ten. They were met at Chester by Mr. A. Dickson of Messrs. Dicksons', who conducted the party to the nurseries. A tour was then made of the various parts of the home nurseries, and after inspecting the houses of Tea Roses, Vines in pots, Ferns, stove plants, Palms in pots, they returned to Chester well pleased with what they had seen. After luncheon at the Commercial Hotel the toasts of the Queen and "Success to the Club" were proposed by Mr. A. Dickson, who presided; the Chairman of the Club, Mr. J. F. Simpson, responding. A hearty vote of thanks to Messrs. Dickson was then proposed by Mr. G. A. Bishop, seconded by Mr. Ambrose. The party then went by steamer up the Dee to Eaton Hall Gardens. In the unavoidable absence of Mr. Barnes, the head gardener, the party were shown round by Mr. Simmonds, the foreman of the plant department. The collection of plants, including the famous Carnations, also different fruit houses, were all admired by the visitors. After passing through parts of the pleasure grounds a return was made to Chester by the steamer, and the homeward journey commenced at eight. The Club is indebted to some of the Vice-Presidents who generously contributed towards the expenses of the outing.

—— NEW PEAS.—I inquired of a large seed grower recently, who has no special Peas, but grows a large collection every year, what varieties amongst new ones had proved to be best with him, and he at once said, "I have found none better than the Gladstone." That variety was so good on the dry porous soil at Chiswick two years ago that it received an award of merit. It is 3 feet in height, a fine cropper, and very green. The 3 feet Peas seen this season not yet widely known, that have also shown fine form, are Sutton's Peerless, Carter's Seedling, and Johnson's Magnificent. Of course in Peas of this habit there must of necessity be much sameness, and it is hard to excel the present best. That we have wonderfully good forms there can be no doubt. It will be difficult to raise others that are superior to them.—A. D.

—— COMPLETION OF THE FLORA OF BRITISH INDIA.—The "Kew Bulletin" says, "With the exception of a general index, now almost ready for the press, this great work has been brought to a conclusion by the issue of the 22nd part, containing the remainder of the Grasses. Sir Joseph Hooker will receive the congratulations of all botanists on the completion of a task to which he has devoted the greater part of the last quarter of a century, to say nothing of previous years of travel and preliminary labour. It would not be too much to say that it has occupied the best part of fifty years of his life, as he left England for India in 1847. The entire work will consist of seven octavo volumes, averaging 775 pages each, including the general index of about 42,000 names. The Grasses alone number 850 species, belonging to 150 genera, and, as has been mentioned before, the synonymy is perhaps more copious and involved than that of any other family. Owing to the wide distribution of most of the genera and many of the species of Grasses, the volume treating of them has a general as well as a special value."

—— SAND-BINDING GRASS.—The Marram Grass (Psamma arenaria), the seed of which was first introduced into the colony of Victoria by the Government Botanist, Baron von Müeller, in 1833, has been proved to be the most effective sand stay ever planted. Practical evidence can be seen of its value in the miles of sandhills now reclaimed by the Marram plantations, sown under the direction of Mr. S. Avery, the park ranger. So complete has been the reclamation of the lands that, where a few years ago not a sign of vegetation was to be seen, there now exists a succulent Grass, eagerly devoured by cattle, and growing to a height of 4 feet. Marram Grass is practically indestructible—burning, cutting, or eating off only makes it thrive—whilst in exposed shifting sand it propagates as surely as in the most sheltered position. The following directions how to plant Marram Grass have been prepared by the park ranger: The Grass to be planted in rows at a distance of 6 feet apart, the space between the plants to be at least 2 feet. The depth to which each plant is put into the sand depends on the nature of the sand. If in sand not likely to drift for two or three months, 9 inches will be deep enough; but in very loose and shifting sand the Grass should be placed from 12 inches to 15 inches deep. A "plant" consists of as much Grass as a man can conveniently hold in his hand.

RUDBECKIA LACINIATA, GOLDEN GLOW.

IT is a stock complaint with many of us that we have too many yellow composites in autumn, and that those we have too much resemble each other. This leads us to view with some distrust the encomiums passed upon new introductions, a distrust too often founded upon past disappointments with so-called distinct novelties. A double Rudbeckia is, however, such a *rara avis* that it is little wonder that many have been persuaded to secure the above variety. The distrust already alluded to was strengthened by the inspection of flowers kindly forwarded last year for examination. These, I fear, were hardly satisfactory to me, and I determined to wait until another season before purchasing Golden Glow.

The award of merit recently made by the Floral Committee of the Royal Horticultural Society is, however, to be taken as a sign that there is considerable value in the variety, even although it has not given general satisfaction in a number of gardens this year. The Floral Committee make remarkably few errors in appraising the worth of flowers, and in this case I am compelled by the view of a plant in flower to add my humble testimony in favour of the award. This plant was in bloom a few days ago in the garden of Mrs. Maxwell-Witham of Kirkconnell, where herbaceous plants are very largely grown.

If this Rudbeckia has a fault it is that of its tall stature, but the appearance of the elegant, well-coloured double yellow flowers was such as to compel admiration, and now I shall not delay adding this variety to my collection of flowers. It is possible that Rudbeckia Golden Glow haas had too dry a position in some gardens this year, and that this may have had something to do with the poor quality of the flowers. We call the Rudbeckias "Cone Flowers," but this variety looks quite unlike the popular name with its double flowers with informal and reflexed florets.—S. A.

Lælio-Cattleya Digbyana Trianæ.

In the spring of this year one of the most beautiful bigeneric hybrids that has ever been seen was shown at the Drill Hall by Messrs. J. Veitch & Sons, Ltd., Chelsea. In general appearance and in attractiveness it much resembles L.-C. Digbyana Mossiæ that emanated from the same source about eight years ago, and which created quite a furore when it was exhibited at the Drill Hall. There is no need for us to say how closely it has followed Lælia (Brassavola) Digbyana, for that may be seen by glancing at the woodcut (fig. 34). Both parents are specified in the name that has been given to it. There were several fine Orchids shown on the same date, but none of them approached the one under notice for chaste beauty. The lip was unquestionably the finest feature of the flower, and was superbly lovely. It was of great breadth, and magnificent fringing with rose purple. Within the frilling the colour was yellow, extending to the throat, at the base of which were some chocolate veins. Both the sepals and petals were delicate purplish rose, but while the sepals were only about an inch wide the waving petals were upwards of 2 inches. The Orchid Committee of the Royal Horticultural Society adjudged a first-class certificate. The plant was subsequently purchased by Sir Frederick Wigan, Clare Lawn, East Sheen, and is now there in the charge of Mr. W. H. Young.

Orchid Specimens.

There can be no doubt that large specimen Orchids are in a measure old-fashioned, and present-day growers think far more of a puny bit of some Rose or unique Cypripedium than they would do of one of the grand old specimen Saccolabiums or Vandas that at one time graced our collections and exhibition tents. It is a pity in many ways that it is so, and for one reason especially that must soon strike anyone in the habit of visiting many large trade or private collections. That is the fact that wherever you go you see in place after place the same stamp of plants, saleroom-sized plants one might almost call them.

We expect this kind of thing at a nursery as a matter of course, as when a large old plant comes into a nurseryman's hands in nine cases out of ten it is cut up for propagating purposes. But perhaps the principal reason for the change will be found in the modern style of building Orchid houses. In place of the lofty spacious houses once in vogue we have narrow low span-roofed structures, and excellent they are for most purposes. For all dwarf growing Alpine Orchids, such as Masdevallias, cool Oncidiums, many Odontoglossums, and others, the 10 or 12-feet houses, with a centre walk and side stages, leave nothing to be desired.

Large plants of a grosser habit of growth must have more room for their full development. They must not be cramped, with their heads about 6 inches away from the glass, and other plants hustling them on either side. In such places they can never be satisfactory, no matter how carefully their wants are attended to in other ways. There is something, too, in the atmosphere of these small houses that does not suit large plants; the temperature is not so steady, and moisture cannot be so regularly maintained.

In many places where these large plants are grown there are large successional vineries where they may be placed during the summer months, at any rate with no detriment to the Vines, and a great deal of benefit both to them and the plants left behind in the Orchid house. The one would be getting the proper atmosphere it needs, the other would be better for the additional room; and in spite of all prejudiced fruit growers may say to the contrary, many beautiful Orchids may be grown and capital crops of Grapes finished in the same house. It has been done time after time, and with a little care and judgment in arranging, and judicious after treatment, there need be not the least fear of injuring the Vines in any way.

Where successional vineries exist there is even greater facility, as the plants may, by being started with the earlier Vines and kept growing with the later ones, have a longer season of growth—an advantage for many species. Take the long-bulbed, erect-growing Dendrobium mosehatum as an instance, or even D. Dalhousianum. Both these must have a long season of growth and be thoroughly ripened afterwards, and I know of no better place for them than a large spacious vinery. As long as the foliage is on the Vines it provides enough shade for them, and afterwards, when the fruit has been cut and the laterals half pruned, the sun reaches the plants and insures the consolidation of the stems.

In early spring, when the Vines are started, considerable attention has to be paid to early morning ventilation, and here again we suit the Orchid admirably, for if there is one thing more than another that militates against the successful cultivation of these lovely plants it is the close stuffy atmosphere they are often exposed to. Let anyone, then, who has those large old specimens crowded in their Orchid houses and stoves give them a chance to recoup their vigour in any of the class of houses indicated, and if they have not previously seen them in such position the rate of progress they make will be a revelation to them.

Some of the finest Aërides I ever met with were growing in a large conservatory, kept at an intermediate temperature, to accommodate a large plant of Stephanotis that grew on the roof, and to maintain in health a collection of large Kentias. A. suavissimum was in a basket over 2 feet across, and carrying eleven beautiful spikes; and the Fox-brush Aërides, A. Fieldingi, was equally satisfactory. I am sure I may say that such plants would elicit unstinted praise from those who are loudest now in deprecating—and rightly—the lanky starvelings that one often sees exhibited as specimen Orchids.

Such plants must be associated with Ferns and other foliage plants to look even passable, but a well-grown distichous-leaved or pseudobulbous Orchid requires no dressing. The quaint forms of growth of the latter, and the noble contour of the foliage of the former, are beautiful in themselves, and show in many cases how carefully considered culture assists Nature. Perhaps the day for these is gone. If so, more's the pity; but that does not alter the fact that they can be grown to give a great deal of pleasure to lovers of well-grown Orchids. —H. R. R.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—September 7th.

The Drill Hall was not overcrowded with produce on the above date, but there were many exhibits of more than average interest. Messrs. J. Veitch & Sons contributed handsomely to the display with Orchids and Pitcher Plants. Mr. Chapman's Sarracenias and Cephalotus were attractive, and Mr. Farr's Crotons imposing. Dahlias of course made a fine display, as did the collections of fruit from the Royal Gardens at Windsor and from Syon House.

Fruit Committee.—Present: P. Crowley, Esq. (in the chair); with Rev. W. Wilks, and Messrs. G. Bunyard, A. H. Pearson, H. W. Ward, G. W. Cummins, T. J. Saltmarsh, G. Reynolds, J. Willard, J. Smith, H. Balderson, G. Wythes, G. Sage, W. Bates, W. Farr, C. Herrin, W. J. Empson, and J. Wright.

Mr. W. J. Coles, The Gardens, Higher Balcombe, sent remarkably fine specimens of the Exquisite Peach. It is a yellow-fleshed American variety, of which its fine appearance is its greatest merit. The fruits were excellently grown, and a cultural commendation was awarded. A similar mark of recognition was accorded to Mr. W. Howe, gardener to Henry Tate, Esq., Streatham, for extremely fine fruits of Stirling Castle Peach grown in the open air. Mr. J. Miller sent from Ruxley Lodge, Esher, fifteen fine Princess of Wales Peaches, and a bronze Knightian medal was awarded; but the triumph in this direction was left to Mr. Owen Thomas, who sent from the Royal Gardens a splendid collection of Peaches and Nectarines grown against open walls, twenty-two dishes of the former, and fifteen dishes of the latter, also two fine dishes of the Golden Jubilee Tomato, and a silver-gilt medal was unanimously awarded. Open air Peach culture is evidently not yet a lost art.

Mr. C. Martin, Clarence House, East Cowes, sent a handsome, well-netted Melon, named Sixtieth Reign, raised from seeds sown 7th May this year, and the plants grown in an unheated pit. The variety is the result of a cross between Royal Favourite and Blenheim Orange. The quality, though good, was not considered quite good enough for an award, and it might be better with the fruits ripened under more favourable circumstances. Mr. C. Herrin sent two seedling Melons, to one of which, named *Mrs. Herrin*, large netted, thick, nearly white, fleshed fruit, an award of merit was granted. La Favourite, raised by Mr. Herrin about a dozen years ago, was one of the parents of the new variety. Several other Melons were shown, more or less unripe, and passed, except twenty-four fine fruits from Mr. W. Kemp, The Gunyah, Barnes, for which a silver Banksian medal was granted.

Sprays of a seedling Nut were sent by Mr. W. Mitchell, Farnham Royal, similar to the Frizzled Filbert; also sprays of an improved Blackberry, *Mitchell's Seedling*, raised from the common Bramble. Both the trusses and individual fruits are very large, and an award of merit was accorded.

Mr. W. W. Taylor, Forest Hill, sent three excellent bunches of Madresfield Court Grapes, for which a cultural commendation was unanimously granted.

Mr. W. Farr exhibited a plant of a Tomato wreathed with fruit to a length of 6 feet (cultural commendation). Wonderfully prolific Tomato plants of Campbell's Prolific were exhibited by Mr. John Russell, Richmond, and the variety is to be tried at Chiswick.

Mr. W. Miles, Down, Kent, sent fine clusters of a dark blue seeded Scarlet Runner Bean. Referred to Chiswick for trial. Mr. W. J. Empson sent splendid Scarlet Runners, Hill's Prize (Bunyard), which was honoured at Chiswick a few years ago.

Mr. G. Wythes exhibited an extensive collection, comprising seventy dishes of fruit of various kinds, and was unanimously granted a silver Knightian medal.

VEITCHIAN PRIZES FOR APPLES AND PEARS FOR FLAVOUR.—*Apples.*—First, Mr. Mayne, Bicton Gardens, with Kerry Pippin. Second, Mr. G. Wythes with Gravenstein. *Pears.*—First, Mr. C. Herrin, Dropmore, with Williams' Bon Chrêtien. Second, Mr. Wythes, with the same variety. There was a good competition of seventeen dishes.

FLORAL COMMITTEE.—Present : W. Marshall, Esq. (in the chair) ; with Messrs. J. Fraser, H. B. May, J. Jennings, G. Paul, C. J. Salter, W. Bain, J. W. Barr, G. Gordon, J. D. Pawle, H. Turner, C. T. Druery, G. Nicholson, R. M. Hogg, and C. Jeffries.

Mr. E. K. Eames, Fulwell Nurseries, Twickenham, sent a number of plants of Eucharis amazonica. They were in excellent health and carrying fine flowers (silver Flora medal). Messrs. J. Cheal & Sons, Crawley, staged a handsome collection of Dahlias, comprising fresh and brightly coloured examples of Cactus, Pompon, single, and large varieties. Amongst the Pompons were noted Marion, Bacchus, Purity, Nerissa, Sunny Daybreak, Dr. Jim, and Clarissa. Of Cactus varieties the best were F. C. Pawle, King of Siam, Matchless, Fusilier, Mrs. Gilliat, Beatrice, and Lady Penzance. Conspicuous in the singles were Fred Leslie, Miss Roberts, Amos Perry, Naomi Tighe, Demon, and Folly (silver Flora medal). Mr. W. J. Godfrey, Exmouth, sent Chrysanthemums Barbara Forbes and Queen of Earlies.

Mr. E. F. Such, Maidenhead, exhibited a number of Cactus Dahlias of fair quality that were spoiled by the arrangement. Very handsome were the striped French Marigolds from Messrs. Dobbie & Co., Rothesay. The strain is evidently a very good one. Messrs. W. Cutbush & Son, Highgate, staged a handsome exhibit of Nerine Fothergilli major, interspersed with small Ferns. The Nerines were in splendid health. Mr. R. Owen, Maidenhead, sent a bright collection of Cannas. The varieties included Général de Mirabel, Italie, Monsieur Colcombet, and others. Messrs. Barr & Son, Covent Garden, occupied their customary position with the inevitable collection of hardy flowers in variety. There were several distinct kinds (bronze Banksian medal).

One of the most handsome exhibits in the hall was formed by the Nepenthes from Messrs. J. Veitch & Sons, Limited, Chelsea. The arrangement was, perhaps, somewhat thin in places for the best effect, but advantageous in allowing every plant to be seen. The most conspicuous were Domini, Curtisi superba, mixta Chelsoni, Curtisi, Hookeriana, Dicksoniana, Cincta, Mastersiana red var, Wittei, Morganiæ, Northiana, and a new one named Tiveyi, which is very handsome. The same firm also sent hardy flowering shrubs, such as Hibiscus cœlestis, single Painted Lady, totus albus, and Lady Stanley, with Acidanthera tricolor, Robinia hispida, Andromeda arborea, and others (silver-gilt Flora medal.)

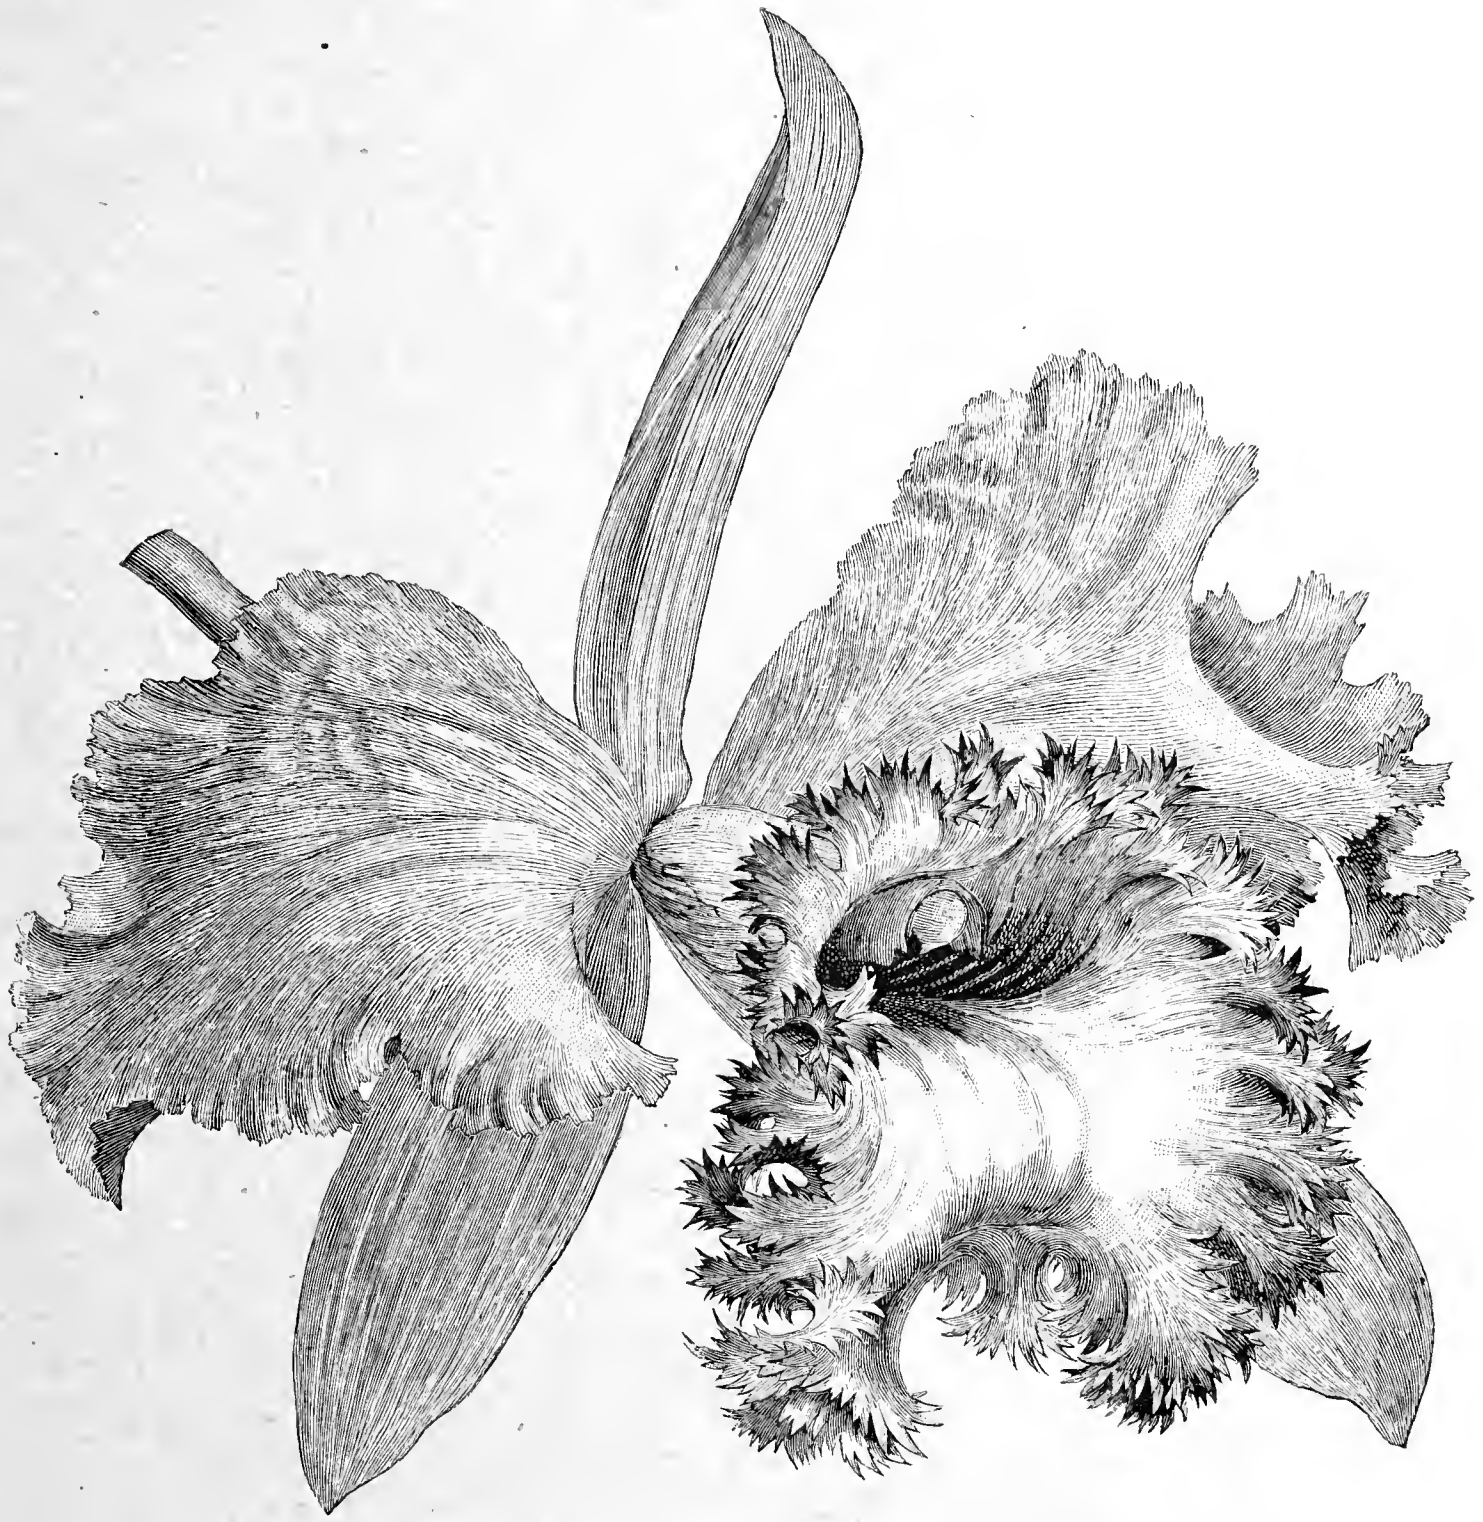

FIG. 34. LÆLIO-CATTLEYA DIGBYANA TRIANÆ.

Mr. H. J. Chapman, gardener to R. I. Measures, Esq., Cambridge Lodge, Camberwell, sent in a most interesting collection of Sarracenia and Cephalotus follicularis. The Sarracenias comprised Courti, Chelsoni, Stevensi, crispata, californica, and others (silver-gilt Flora medal). Without the group of Crotons shown by Mr. W. Farr, gardener to A. F. Pears, Esq., Springrove House, Isleworth, the Drill Hall would have looked somewhat empty. The plants were splendidly grown and the colours very good, but the light is not good enough in the hall for the plants to be seen to the best advantage (silver Flora medal).

ORCHID COMMITTEE.—Present : H. J. Veitch, Esq. (in the chair) ; with Messrs. J. O'Brien, H. M. Pollett, T. Statter, J. T. Gabriel, F. J. Thorne, T. W. Bond, C. Winn, A. H. Smee, H. J. Chapman, T. B. Haywood, and J. Douglas.

The only collection of Orchids of any size was that of Messrs. J. Veitch & Sons, Ltd., which was very beautiful. The plants included several kinds, and as considerable care and taste had been exercised in staging, an excellent effect was produced. There were Odontoglossums, Oncidiums, Cattleyas, Lælio-Cattleyas, Aërides, Cycnoches, Cypripediums, and several others (silver Flora medal). Mr. T. Stafford, gardener to

F. Hardy, Esq , Tyntesfield, Ashton-on-Mersey, sent a few Orchids (silver Flora medal), as did one or two other exhibitors, including Mr. F. J. Thorne, gardener to Major Joicey, Sunningdale Park, who exhibited a splendid specimen of Aeineta bieolor.

CERTIFICATES AND AWARDS OF MERIT.

Cattleya Euphrasia (J. Veitch & Sons, Ltd.).—A superb hybrid resulting from a eross between C. superba and C. Warscewiczi. The sepals and petals are rieh rose purple, and the magnificent lip deep velvety erimson with a lemon eoloured throat (first-class eertifieate).

Dahlia F. C. Pawle (J. Cheal & Sons).—A handsome Cactus variety of good substance. The eolour is rieh crimson, occasionally flushed with purple (award of merit).

Hibiscus Manihot (J. Fulford).—A beautiful flower, pure yellow in colour. When the bud is expanding it has much the appearance of an Evening Primrose (award of merit).

Michaelmas Daisy Mrs. W. Peters (W. Peters).—A seedling with white flowers. The height is about 2 feet, and the plant is extremely floriferous (award of merit).

Nepenthes Tiveyi (J. Veiteh & Sons, Ltd.).—New Nepenthes are seldom seen. The one under notice resulted from a cross between N. Veitchi and N. Curtisi superba. The pitchers are medium to large in size, and wonderfully even in shape. The ground colour is pale green, and the profuse marking ehocolate brown (first-class certificate).

Rhynchostylis cœlestis Cambridge Lodge var. (H. J. Chapman).—This is a dark form of the type (award of merit).

BRIEF NOTES ON ALPINE FLOWERS.

(*Continued from page* 168.)

ACANTHOLIMON GLUMACEUM.

THIS "Priekly Thrift" is by no means a rare plant, nor one which is difficult to grow. While it is thus less likely to be coveted by growers of rare alpines, it is one of the almost indispensable plants for the rock garden. It much resembles in flower an abnormally dwarf Statice, and has, indeed, been by some included with these plants under the name of Statice Ararati.

A native of Armenia, it is quite hardy, although sometimes injured by frost in severe winters. It forms a neat mound of narrow and crowded leaves, spiny at the points. The flowers are of a rose eolour, and are produced on spikes, which rise a little above the tufts of leaves. The whole plant is only about 6 inches in height. A. glumaceum prefers a light well-drained soil, but is none the worse for having a fair supply of water in summer, provided the position is a sunny one. This full exposure to the sun ought to be secured in any soil. The Prickly Thrift is valuable for slopes or terraces of the rock garden, or for rockwork edgings to walks. It is much more easily grown than its scaree and diffieult congener, A. venustum. It is inereased by cuttings.

ACHILLEA AGERATIFOLIA.

This Greek Achillea is but seldom met with under Bentham and Hooker's name of A. ageratifolia, Grisebaeh's one of Anthemis Aizoon being more commonly followed in garden praetice. It is a very desirable little plant, and certain to be appreciated by those who like modest yet attraetive beauty in foliage and flower. The flowers themselves are something like those of a white Daisy in general appearance, with fourteen to eighteen broad ray florets. The leaves are equally attractive from their whiteness and the manner in which they are serrated. The whiteness is eaused, as is frequently the ease, by the presence of a down on the leaves. A. ageratifolia grows about 4 inches high. It likes a moderately light and dry soil, and flowers well in one with limestone or chalk among it. It is a little tender in some localities, and is occasionally lost in others from the effeet of excessive rains in winter.

CONVOLVULUS LINEATUS.

The "Pigmy Convolvulus," as it is occasionally called, is a pretty little plant whieh is, unfortunately, the cause of much trouble and disappointment to its owners. This is principally due to its shy-flowering habit in a large number of gardens. I have been often asked about this, but it would be affectation to say that one is able to preseribe an unfailing cure for so great a defect. The more we know of some flowers the less likely are we to dogmatise on the score of their requirements, or to say that a certain treatment will insure success. Judging from considerable observation of this little Convolvulus, I think, however, that a good firm soil well drained, but with an ample supply of water in summer, is most likely to give satisfactory results.

On a poor and rather dry soil it seldom gives much satisfaction, and in such its habit of sending out underground runners, a feature on all soils but even more marked on a poor one, suggests better feeding than the plant generally receives. This running habit makes it troublesome among other dwarf flowers, but may be counteracted by enclosing the plant so that its runners eannot trespass upon others. When this is done it may beeome partially exhausted and should be lifted every few years, reduced, and replanted in fresh soil. The whole plant only grows from 3 to 6 inches high, and a mass looks very pretty with its lance-shaped silky leaves. The flowers are a pretty rose and are nearly an ineh across.

ERICA VAGANS ALBA.

Heaths are of the utmost value in the rock garden, their generally neat habit and profuse flowering making them unfailing favourites. The number of species and varieties is large, and all the hardy ones can be utilised with advantage where there is sufficient space. The white variety of E. vagans, the Cornish Heath, finds much favour either in or out of flower. As these lines are written a large plant crowning the summit of a roekery is very handsome, with its racemes of white flowers with pro eeting chocolate-coloured anthers. In a rather dry place, it flowers well every year, but requires in continued dry weather an oeeasional soaking with water. One hot summer this was neglected, with the result that it took the plant a year or two to recover properly from the effeets of the drought.

E. vagans alba is not at all difficult to obtain, and if inerease of stock is required division of established plants may be practised. Space will not permit of dealing with some other useful Heaths, but one may mention that one of the best of the white-flowered plants of the same natural order is Calluna vulgaris Hammondi, generally a most satisfactory plant for autumn bloom.—ALPINUS.

(To be continued.)

EATON HALL.

THE palatial seat of the Duke of Westminster is about three miles from the ancient City of Chester, with its cathedral and Roman walls. Visitors from Chester may enter the park by the Overleigh Gates, just without the City, or may go by steamer up the classical River Dee to Eeeleston Ferry, a few minutes' walk from the Hall. As is well known, his Grace is reekoned to be the richest man in England. His income from London property alone is estimated at £800,000 per annum.

The family of Grosvenor, Dukes and Marquises of Westminster, is descended from Gilbert Le Grosvenor, who came over with William the Conqueror. They were people of high standing in Normandy for 150 years anterior to the Norman Conquest, and held the high and honourable offiee of Le Grovenour. Gilbert Le Grosvenor, according to "Collins' Peerage," was nephew of Hugh Lupus, the great Earl of Chester, who was nephew of William the Conqueror, his father being Riehard Earl of Avranches in Normandy, and his mother Emma, the King's sister. Hugh Lupus was invested with the Earldom of Chester in 1070 by his uncle, and had jurisdietion over all Barons within the eounty, excepting the Bishop. A bronze equestrian statue of Hugh Lupus stands in the courtyard of Eaton.

It is not of the glories of Eaton that I intend to write. My visit being a hurried one I am only able to reeord indifferently what I saw in the large corridor and a few plant houses around. The eorridor, running from north to south, is 360 feet long, 12 feet wide, and about 20 feet high. It has narrow borders on each side of the broad walk, in whieh are planted elimbers which hang in graeeful negligence overhead. Amongst the large plants in flower were Fuchsia corallina and F. fulgens, hanging in pendulous raceme s ; three large plants of Bougainvillea glabra, remarkable for the intenso mauve colour of the bracts. This is evidently the result of cool treatment and abundanee of light, as grown in a stove we heard eomplaints of the dullness of their colour. A large Plumbago capensis was full of its cold pale blue flowers ; Cassia corymbosa was a mass of gold ; Brugmansia suaveolens was drooping with its long white trumpet flowers. A large Heliotrope added its beauty and fragrance to the scene. Abutilon Boule de Neige was truly named a ball of snow. Amongst other plants elothing the sides and roof of the eorridor were Cobœa scandens variegata and Oleanders. The pathway borders were gay with large plants of Liliums speciosum rubrum and speciosum Kraetzeri, Campanula pyramidalis in 10-inch pots with an average of six spikes of bloom to eaeh plant, also rich Cannas and graceful Fuchsias.

On the eastern side of the eorridor is a delightful Water Lily house, about 40 feet long by 30 feet in breadth. The sides of the tank are about 3 feet above the pathway whieh runs around the house, whieh has side stages. The tank occupies the whole eentre of the housc, and its sides are fringed with Ferns, Tradescantia, and Panicum. At intervals rising from this leafy groundwork are miniature groups of Aehimenes, Gloxinias, and Capsieum Prince of Wales, profusely berried ; also Crotons, and Clerodendron fallax in full flower. Up the pillars around the tank are entwined Thunbergia alata and T. alata alba. Festooning the roof Bignonia venusta is laden with its purple flowers, and Jasminum grandiflorum emits its sweet perfume. Several large hanging baskets are suspended from the apex of the roof, all excepting two being Aehimenes, and these two Mierolepia hirta cristata.

I noticed elose to the eorridor a houseful of flowering Cannas, and another of Plumbago rosea for winter flowering in 6 and 8-inch pots. Suspended from the roof in this house were hanging baskets of Asparagus deflexus, and on the shelf Smilax asparagoides for eutting. Another house was full of Eranthemum pulchellum and Bouvardias for winter flowering ; the rafters were elothed with Dipladenia boliviensis in profuse flower. I observed in another house a portion of the Malmaison Carnations that were awarded the gold medal at the last Chester show, and had reeently been placed in 8-inch pots.

The fruit houses, Orchid houses, kitehen garden, and parterre I do not presume to describe, but leave them to others with more time and facile pens ; but I can say there is no question but that the ducal gardens are ably managed by Mr. Barnes, who is equal to his duties and the control of the fifty men who are employed in their keeping.—F. STREET.

To the Members of the National Rose Society.

I do not think that any member of the N.R.S. who is interested in its welfare can be quite satisfied with its present condition. It is true that each year our schedule of prizes becomes more and more enlarged; that new classes are originated, and that some few of our members generously come forward to offer an additional stimulus to exhibitors; that we have issued several publications, and that the number of the societies affiliated with us does not diminish; but at the same time there seems to be that want of enthusiasm without which no cause can prosper.

It is probably the very fact of our having always a credit balance at our bankers at the end of the year that leads our members to be satisfied with the present condition of things; but when we consider that the number of our members has not of late years increased, I do not at all think that we can congratulate ourselves overmuch. This opinion has been expressed by many, and various suggestions have been made as to how it is to be remedied. Many of these seem to me unpractical and impracticable, and I have therefore felt constrained, as the founder of the Society and not in any official capacity, to make this appeal.

I want to ask you, my friends, if each one of you cannot procure an additional member? There are many, both professional and amateurs, who have received considerable sums as prizes who have never as yet brought us one member. Will you not, then, bestir yourselves, and see if you cannot remedy this great defect? Of course, I do not anticipate any immediate response to this, as we are drawing towards the end of our year, but I do want you to think over it and lay to heart the suggestion I have made.

Let me again say that this move is an entirely independent one, and in no way compromises anyone but myself; but I feel it is necessary to make this appeal when I note the steady, and in fact rapid, advance of other societies devoted to various branches of horticulture, while our society is practically merely holding its ground.—H. Honywood-D'Ombrain.

Rose Souvenir de la Malmaison.

If I were compelled to grow only one Rose, and had my choice of variety, I should certainly decide in favour of this old Bourbon. It comes as near to perpetual blooming, without any special pains being taken with it, as any Rose of good form that I know. It has a splendid constitution, growing and flowering as freely at twenty years old as it does as maidens.

Cuttings of this variety root very freely, and it grows as vigorously on its own roots as when budded on any stock. Unless the autumn is very wet, the late blooms are as good, and often better, than the earlier ones, and it will not cease blooming until the weather becomes so bad that the unopen buds rot on the trees.

In pruning this Rose only the weak shoots should be removed, and the strong ones slightly cut back; otherwise the bush should be allowed perfect freedom. The colour of the blooms is a delicate pale blush, and it has a pleasing perfume. Have other growers their favourite Rose? If so, what is it?—J. H. W.

NOTES ON GOGERDDAN.

Having recently been on a holiday visit to Aberystwith, I heard much of the beauties of Gogerddan, the seat of Sir Pryse Pryse and Lady Pryse. The estate is situated about three miles from the resort mentioned, and the drive through charming Welsh scenery is most enjoyable. The gardens are about 4 acres in extent, and the houses strong and well built. In a lean-to vinery we saw a splendid crop of well finished Black Hamburghs, and we also noticed a rod each of Lady Downe's and Foster's Seedling, carrying fine and well coloured bunches. Adjoining this house is the late vinery, in which the Hamburghs were just beginning to colour. The clean, healthy foliage denoted high culture and careful management.

A block of three span-roofed structures, comprises two fine greenhouses, with the stove in between them, the cool portions of which contained a fine show of flowering plants, notably Begonias, Petunias, and Zonal Pelargoniums, Liliums, Fuchsias, bearing a wealth of flower, while along the back of the stages, planted in large pots, were two superb Abutilons in full flower. Lapageria rosea and alba, Hoya carnosa, and Passiflora Buonapartea, all help to make a charming display. The stove is a lofty structure with a centre bed, in which we saw some choice specimen Palms, while on the side stages were well grown Ferns, a Cissus discolor, Stephanotis trained on balloons, and by the door a splendid specimen Croton Weismanni; on the roof were an Allamanda in full bloom, Bougainvillea glabra, and Clerodendron Balfourianum. In a neighbouring structure there was a grand show of Crotons, Dracænas, and Pandanus, which will make nice table plants.

Along the whole length of a high wall running across the centre of the garden, separating it into two parts, is a row of Peach houses, with a southern aspect. There is the early Peach house, cleared of its fruit; another with its beautiful fruit now ready, while a third is devoted to late varieties that will carry on the supply for a long time to come. The chief varieties grown are Nectarines Elruge and Lord Napier, while of the Peaches there are Early Rivers, Noblesse, and Stirling Castle, with others. Planted out along the front, and trained up under the glass, was a splendid row of Tomatoes, carrying heavy crops of handsomely finished fruit, the varieties being Ham Green Favourite, Perfection, Market Gem, and Peach Blow.

Chrysanthemums are also in evidence, for along the side of a walk were some tall specimens, intended for cut blooms for exhibition, their healthy dark-green foliage showing they are well looked after; while in another place was a useful collection of bush plants, which should produce good blooms later in the year.

The kitchen garden, a model of cleanliness and order, is stocked with all kinds of vegetables. To enumerate all would take far too much space. On the whole the gardens are a credit to Mr. James Vearey and his staff, and bespeak careful and well-considered culture. Across the road is the mansion, with its attendant pleasure grounds and flower garden. The flower beds were charmingly arranged, and presented a mass of colours, well blended. By the kindness of the owners these gardens are open to the public on every day except Sunday.—A. E.

HORTICULTURAL SHOWS.

READING.—September 1st.

In most inauspicious weather the Reading Horticultural Society opened its summer exhibition. Rain came down in torrents, and strong winds prevailed. Horticulturally the show was one of the best the Society has had, all sections being well represented, although the place of honour must be given to the vegetable classes. The many collections set up were indeed superb, and we may safely say that a standard of such excellence has not been reached at any other show this season. The fruit staged in the various classes was of good quality, while groups and specimen plants all added to make a fine display. Cut flowers were also well represented in the classes allotted them. Messrs. J. Veitch & Sons, Ltd., R. Wallace & Co., J. Laing & Sons, and J. Hudson had beautiful non-competitive exhibits.

There were three entries in the class for a group of plants arranged for effect, occupying a space 18 feet by 10 feet, and in addition to the money the Sutton challenge cup, value 25 guineas, goes with the first prize. Mr. Peel, gardener to Miss Todd, Southampton, was the winner with a pleasing arrangement. Mr. Pope, gardener to J. P. White, Esq., was very close second. Mr. Bassil, gardener to D. H. Evans, Esq., third. For the best group in a space 10 feet by 8 feet Mr. Chamberlain, gardener to F. M. Lonergan, Esq., was successful, followed by Mr. Alexander, gardener to R. Hewett, Esq., and Mr. Goddard. Specimen plants were well staged by Mr. Wm. Finch, Coventry, who took first place. Mr. Peel was second. For the best six stove or greenhouse Ferns Mr. Willis, gardener to H. C. Symonds, Esq., was a splendid first, Mr. Leith and Mr. Peel being second and third in the order named. For the best six plants for table decoration Mr. Fulford, gardener to F. D. Lambert, Esq., was to the front; Mr. Pope second; and Mr. Best third. Fuchsias were superb. Mr. Bright, gardener to J. B. Karslake, Esq., was a splendid first; Mr. Wilson second, also having a fine lot, Mr. Hinton taking third place. Messrs. R. Wallace & Co., Colchester, staged half a dozen Liliums, and were awarded the prize. Coleus were good, Mr. Hammond, Mr. Goddard, and Mr. Ferry being the winners. For three Palms Mr. Peel was a good first with healthy plants, Mr. Hammond taking second place. Begonias were represented by nice plants. Mr. Bassil staged the best, Mr. Smith second, and Mr. Mayne third.

Dahlias were very good. Mr. J. Walker, Thame, was placed first for eighteen Show varieties. Mr. Mortimer was a splendid second; and Messrs. J. Cheal & Sons third. Mr. Mortimer took first place in a similar class for Cactus kinds; Messrs. Cheal & Sons second. The last named were a good first for single Dahlias; Mr. Such second. Asters, Gladiolus, and Zinnias were all well staged, and the display made in the hardy cut flower classes was very fine.

Fruit made a fine display. For the best eight dishes Mr. Gleeson, gardener to C. E. Keyser, Esq., was a fine first with Black Hamburgh and Muscat of Alexandria Grapes, Barrington Peach, Golden Perfection Melon, a fine Pine, Nectarines, Figs, and Cherries. Mr. Pope, gardener to the Earl of Carnarvon, was second; and Mr. Cole third. In the class for six dishes Mr. Howard, gardener to Mrs. Myers, Benham Park, was first with fine Pincapple Nectarines, Suttons' Scarlet Melon, Stirling Castle Peach, Kirke's Plum, Black Hamburgh and Muscat Grapes. Mr. Chamberlain was a creditable second; Mr. Bassil third.

There were five entries for three bunches of Black Hamburgh Grapes. Mr. W. Fyfe, gardener to Lord Wantage, was first with grandly coloured examples, Mr. Cole second, and Mr. Wilson third. Mr. Fyfe was also first in the class for any other Black, staging Madresfield Court in perfect form. Mr. C. Cooper was second with Gros Maroc; Mr. Cole third. For the best three bunches of Muscat of Alexandria Mr. Fyfe was again successful with superb examples, Mr. Cole second with larger bunches not nearly so well finished. For the best dish of Peaches twelve staged, Mr. Bowerman winning with fine Barrington; Mr. Leith second, and Mr. Cole third. For six Nectarines Mr. Howard was awarded the prize, staging Pineapple, Mr. Gleeson second, Mr. T. Turton third. The last mentioned exhibitor won for Figs, followed by Mr. Bastin. Mr. Turton

also had the best three dishes of Plums; Mr. Bowerman took second place, and Mr. Osborn third.

Dessert Apples were good. For the best three dishes, Mr. Turton won with Irish Peach, Miller's Seedling, and Worcester Pearmain; Mr. Ross second, and Mr. Fyfe third. For culinary, Mr. Ross scored with Stirling Castle, Warner's King, and Ecklinville Seedling; second, Mr. Webb, and Mr. Osborne third. The best scarlet Melon was staged by Mr. Booker, and the best green flesh by Mr. Mortimer, a delicious fruit named Sutton's Perfection. For three dishes of dessert Pears Mr. Taylor was successful, and Mr. Chamberlain a good second.

All the lions of the vegetable kingdom were at this show, and the produce staged made a most imposing display. For the seven valuable prizes offered by Messrs. Sutton & Sons for twelve dishes, in not less than nine distinct kinds, there were fifteen competitors. Mr. Lye, gardener to Mrs. Kingsmill, Sydmonton Court, was a splendid first with Autumn Mammoth Cauliflower (grand in every way), Best of All Bean (splendid), fine Prizetaker Leek, superb Carrots and Beet (Blood Red), with Snowball Turnip, Autocrat Pea, Satisfaction Potato, Sulham Prize Celery, Perfection Tomato, Student Parsnip, and Selected Ailsa Craig Onion. Mr. Bowerman, gardener to C. Hoare, Esq., Hackwood Park, was second with a very fine lot, Beet, Carrots, Beans, Potatoes, Turnips, Leeks, and marvellous Onions being his best dishes. Mr. Fyfe, gardener to Lord Wantage, was third, his Beet, Cauliflower, Celery, Onions, and Peas being very fine. Mr. C. Foster fourth; Messrs. Waite, Best, and Pope following in the order given. Messrs. Bastin and T. Wilkins were awarded prizes equal to the seventh. Only two lots staged in Messrs. Webb's class, Mr. Kneller winning with good produce.

Vegetables at the Reading Show.

No doubt you will ere now have received from your reporter an account of the high-class show held on September 1st at Reading, under such deplorable weather aspects. Good all round as the exhibition was, there was no question but that the vegetables arrayed by the best growers and exhibitors of the day in competition for Messrs. Sutton & Sons' valuable money prizes was not only the great feature, really the dominant one, and were universally admitted by all who saw them to be the very finest in quality and general excellence ever seen in the country. A competition of fifteen collections was indeed good, making a total of 180 dishes. Out of these six lots were, though nominally excellent, yet not good enough to point.

That the highest excellence was looked for was natural, having regard to the reputations of the leading competitors. Still farther, it has for years been the case that the best average quality in vegetables found anywhere has always been at Reading. Then there is the fact that the competition is for prizes offered by the great Reading seed firm.

Whilst all the collections pointed had such primary vegetables as Onions, these generally being large and very handsome; Carrots, chiefly the New Red Intermediate; tapering Beets, as a rule not quite up to the correct form, though some were exceptionally good; Celery, either Red or White, and the best very fine and solid, and remarkably free from stain or abrasion; Cauliflowers, the best wonderfully white, solid, and handsome, though some were rather large as others were a trifle small, yet so good all the same. Runner Beans were all of the new Prizewinner or Best of All types, long, straight, narrow, yet thick, fresh, green, and tender; even the cottagers' dishes all seemed to be of this type, and were astonishingly fine also. Tomatoes, all of the Perfection strain, fruits generally even, rich coloured, fresh, not over-large, and very effective. Potatoes were of course in every case Satisfaction. Windsor Castle and some white kidneys were singularly good, though a few dishes were a trifle large; and Leeks, varying much, the best being really first rate. Then found more irregular were dishes of another Potato or Carrot, or perhaps a second lot of Celery, although duplicates did not add to strength. Peas in several cases excellent; Parsnips really first rate, especially those from Lockinge; Globe Artichokes, two lots only, very good, though not highly regarded; and Brussels Sprouts, found in three lots, also not strong features yet, as hardly in season.

That there was no collection absolutely perfect is a matter of course. Mr. R. Lye, who came first, was weak in his Peas, Tomatoes, and Celery, but was strong with Onions, Carrots, Beets, Cauliflowers, Runner Beans, Potatoes, and Parsnips, Turnips and Leeks coming pretty good. Mr. Bowerman, who came second, was strongest with Onions, very fine Ailsa Craig, Runner Beans, Turnips, Potatoes, and Leeks, Carrots, Celery, Tomatoes coming second best, Peas being his weakest dish. Very much in this way did all the pointed collections run, the points of the first five collections being covered by a range of 5 only, and the sixth and seventh, both getting prizes, came within $2\frac{1}{2}$ points; so that a difference of $7\frac{1}{2}$ points was all that existed between the first and the seventh. The eighth and ninth also ran these hard, and Messrs. Sutton & Sons kindly added two other prizes of 20s. each. The first prize was £10, and the total sum given in nine prizes was £34, really a munificent sum.

It seemed a case in which, because of the nearness in merit of the respective collections, that it was an admirable opportunity for testing the plan of pooling the money, and dividing it amongst the competitors according to point value. The Reading firm having this year not only required a moderate number of dishes, but also specified the exact numbers to be shown in each dish, were rewarded by a splendid competition, although half a dozen were clearly out by it. It will soon be needful to have at Reading a champion class for twelve dishes, into which certain leading competitors should go, and a further class for nine dishes, open to all but the champion men. That course would greatly tend to encourage smaller men to compete, whose chances against the giants, if so they may be termed—Lye, Pope, Bowerman, Fyfe, Foster, Waite, Wilkins, and Kneller—are so poor now. It is, of course, a question of means or prizes, and there is ample room for more for vegetables at the Reading Summer Show.—A. D.

Bath.—September 1st and 2nd.

The Bath Floral Fête Committee is most unfortunate in its autumn fixtures. All they need to make their exhibitions successes is fine weather, and this they are rarely favoured with. On the occasion under notice it rained heavily all the first day, and this completely marred the affair. As far as the exhibition was concerned nothing but praise will meet the case. Entries were far more numerous than usual, and the quality of the exhibits in most instances was most satisfactory. Messrs. B. R. F. Pearson and W. Jeffery are the Secretaries.

Fuchsias are invariably the feature in the plant tents, and they were numerously and admirably shown. Mr. G. Tucker, Trowbridge, was first for nine specimens, showing grand pyramids not less than 9 feet high, and in most instances freely flowered. Mr. J. H. Willcox, Bath, was a good second with smaller pyramids. Mr. J. Lye, Sunnyside, Easterton, was third. The first prize for six plants was awarded to Mr. W. J. Mould, Bath. Mr. Henry Pocock, Hilperton, was second. For four varieties Mr. A. Young, gardener to Lady Pitman, Bath, was a good first with fine well flowered specimens; second, Mr. C. Adlam, gardener to J. A. Martin, Esq., Bath. The prizes for single specimens of different colours were divided among the leading growers named, the competition being keen.

For a collection of stove and greenhouse plants in and out of flower Mr. J. Cypher, Cheltenham, was easily first, showing grand Kentias, Crotons, large and highly coloured Allamandas, and Ericas. Mr. Vause, Leamington, was second. The best bank of fine-foliaged plants was shown by Messrs. E. S. Cole & Sons, Bath. With six flowering plants the competition was close. Mr. J. Cypher was placed first for grand specimens of Erica Eweriana, Bougainvillea Cypheri, Phœnocoma prolifera Barnesi, Statice intermedia, Allamanda nobilis, and Clerodendron Balfouri. Mr. Cypher was first and Mr. Tucker second for Ericas. There was good competition with single specimen stove and greenhouse plants, and also in the classes for Liliums and Coleuses. All the foregoing were arranged on turf banks in one large tent.

The exhibits in a second large tent were more varied and equally attractive. The principal feature was the groups arranged for effect on a space not less than 100 square feet. Mr. Cypher was well first with a light and elegant combination of choice plants, virgin cork, and moss, which answers so well when the materials employed are perfect and tastefully arranged. Mr. A. Tanser, gardener to R. B. Cater, Esq., Bath, was second with a very pretty arrangement, lacking a little in colour, while the third prize went to Mr. Vause. Mr. Tucker was a good first for twelve Ferns, and Mr. T. Truckle, gardener to Thomas Carr, Esq., Bath, first for six Ferns in well-filled classes. The side tables in this tent were wholly occupied by cut flowers, the greater part of which were staged for prizes. Gladioli made a fine display. Mr. S. Bird, gardener to H. Fox, Esq., Wellington, was first for eighteen varieties, and for twelve spikes Mr. F. Hooper took the lead, followed closely by Mr. J. Tont.

Dahlias were remarkably good. For twenty-four varieties, Messrs. Keynes, Williams & Co., Salisbury, were first, and Mr. G. Humphries, Chippenham, a very close second. With twelve varieties Messrs. J. Cray and Son, Frome, were first, and Mr. T. Haskins second. The best stand of Fancies was shown by Mr. G. Humphries; second, Messrs. Keynes, Williams & Co. In the classes for Roses Mr. J. Mattock, Oxford, was easily first for twenty-four varieties, and also for twelve Teas. Mr. J. Bolwell, gardener to Dr. Budd, Bath, and Mr. George Garraway also showed well in the Rose classes. An assortment of very fine varieties gained Messrs. G. Cooling & Son, Bath, the first prize for twenty-four trusses of Zonal Pelargoniums, Mr. G. Humphries being a good second. There were no less than six competitors in the class for twenty-four bunches of stove and greenhouse flowers, a very choice collection staged by Mr. T. Wilkins, gardener to Lady Guest, being first. The second prize went to Mr. G. Hallett, Bath. For twenty-four varieties of hardy herbaceous flowers Mr. A. A. Walters, Bath, was first, and Messrs. Cooling & Sons, Bath, second, the quality of these two exhibits being remarkably good. Mr. G. Garraway was first for annuals, and Mr. F. Hooper second.

Messrs. G. Cooling & Sons arranged a grand display of garden Roses in bunches, not for competition, with a view to showing how continuous and free-flowering many of these old-fashioned Roses are. Messrs. J. Cray & Sons, Frome; and also Mr. G. Humphries, Chippenham, exhibited Cactus and other Dahlias extensively, not for competition. A third tent was filled with vases, dinner-table decorations, bouquets, and wild flowers, and altogether a very attractive display was made.

The tent wholly devoted to fruit reminded us of the palmy days of the Bath Association. Such a grand display of all fruit in season has not been seen at Bath for several years past. For a collection of eight dishes Mr. W. Strugnell, gardener to the Right Hon. W. H. Long, M.P., was well first, showing good Alicante and Muscat of Alexandria Grapes, Hero of Lockinge Melon, Bellegarde Peaches, Pineapple Nectarines, Brown Turkey Figs, Washington Plums, and Williams' Bon Chrêtien Pears, all prettily arranged with Ampelopsis Veitchi. Mr. G. Pymm, gardener to Mrs. Gouldsmith, Trowbridge, was second; and Mr. T. Wilkins third. There were five competitors, with eight bunches of Grapes in four varieties, and all staged bunches well above the average in quality. Mr. W. Taylor, gardener to Alderman Chaffin, Bath, was first, having

grand clusters of Alicante and Gros Maroc, and good Black Hamburgh and Muscat of Alexandria. Mr. W. Mitchell, gardener to F. W. Fleming, Esq., Chilworth Manor, was a close second, his Black Hamburgh and Mrs. Pince being remarkably well finished. Third, Mr. W. Taylor, gardener to C. Bayer, Esq., London. The Madresfield Court in this collection were very fine.

Fifteen competed with three bunches of Black Hamburgh, but Mr. W. Mitchell was easily first, followed by Mr. Allen, gardener to W. Marsh, Esq., Bath ; third, Mr. W. Taylor, Bath, In the any other black class Mr. C. Bayer was a good first with Madresfield Court, second Mr. W. Mitchell. Eight competed with white Muscats. Mr. Carpenter, gardener to A. R. Baily, Esq., Frome, was first with beautifully ripened Muscat of Alexandria, the second prize going to Mr. Bayer. The any other white class was also well filled. First, Mr. W. Marshall, gardener to J. Doyle, Esq., Clifton, who staged perfectly ripened Buckland Sweetwater ; second, Mr. T. Cloote, gardener to D. E. Taylor, Esq. Local growers were well represented in the class for Grapes set apart for them. Mr. S. Hodges, gardener to J. Fort, Esq., was first for good Muscat of Alexandria, and Mr. Marsh second with excellent Gros Maroc.

Melons were numerous, and the quality exceptionally good. Mr. W. J. Atkins, gardener to Mrs. Greaves, was first for a scarlet flesh variety, showing Suttons' A1 of excellent quality, Mr. E. Mallinson taking the second prize. Very good also was the first prize fruit of Imperial Green-flesh, shown by Mr. J. Duckett, Chippenham ; and the second prize fruit of the same variety, shown by Mr. Strugnell. Peaches and Nectarines were numerous and good. The principal prizewinners with these were Messrs. Atkins, T. Ackland (gardener to A. G. Hayman, Esq., Frome), W. Carpenter, W. Strugnell, W. Taylor, and J. Clarke (gardener to J. C. Aiken, Esq.). Plums, Figs, Apples, Pears, and Filberts were represented at the rate of about twenty entries in a class, and a grand variety was shown. Mr. Strugnell was among the most successful in these classes ; Mr. G. Garraway, Mr. J. Manning, Mr. Wilkins, Mr. A. Keevil, and others also taking prizes. Messrs. Cooling & Sons, Bath, staged a row of heavily fruited Apple trees in pots, just as lifted from the open ground ; and a collection of Apples and Pears in dishes.

Numerous classes were provided for vegetables, but these were arranged in the open, and a report of prizewinners could not be taken in a drenching rainfall. Mr. T. Wilkins, Inwood, and Mr. Garraway, Bath, were the most successful with collections.

WIRRAL AND BIRKENHEAD.—September 1st and 2nd.

On Wednesday and Thursday last, under most distressing circumstances as regards the weather, the annual show in connection with the Birkenhead Agricultural Society was opened on the Society's grounds. On the whole the exhibits were of excellent quality, this being most noticeable in the fruit and vegetable classes, which were really excellent, the former being especially fine and keenly contested. Plants, with the exception of Palms and Ferns, were lacking both in colour and flower ; but taking the season into consideration the show was of great excellence. As usual the Stewards, with the indefatigable Secretary, Mr. A. H. Edwardson, were assiduous in their attentions to all present.

For ten flowering and foliage plants Mr. J. W. Tottey, gardener to W. Laird, Esq., was placed first, Crotons Queen Victoria and Countess and Vinca alba being the best. Mr. S. Haines, gardener to E. K. Laird, Esq., second ; and Mr. A. Brown, gardener to Geo. Webster, Esq., third. Groups arranged for effect were not up to former years. Mr. Bradshaw was first; and Mr. J. D. Grindley, gardener to Mrs. Blackburn, second. Mr. A. Brown won class for three stove and greenhouse plants in flower with good Statice profusa, Vinca rosea, and a Pelargonium. Mr. Tottey was second. The order was reversed for three foliage plants, Mr. Tottey also winning classes for one Palm, one foliage plant, one Tree Fern, three Coleus, one Fuchsia, and three table plants. Mr. A. Brown was successful for one greenhouse plant in bloom, one stove plant in bloom, and for three Begonias. Messrs. Haines and Grindley were successful in classes for three Ferns and one Fern. Orchids were much improved, Mr. E. Taylor, gardener to E. Pryor, Esq., took first for three with a lovely piece of Cattleya Eldorado alba and Oncidiums sarcodes and incurvum. Mr. J. Bracegirdle, gardener to W. H. Watts, Esq., was a close second. Hand bouquets, ladies' sprays, and gentlemen's buttonhole bouquets were superb, the winners being Messrs. S. Johnson, J. Clarke, and J. Williams, gardener to C. J. Procter, Esq.

Dahlias were excellent, the Cactus varieties coming in for great admiration ; Messrs. A. J. Stanley and F. Davies, gardener to J. H. Howell, Esq., being the winners in a very strong competition. The doubles shown by Mr. Clement Aldred were charming. Mr. Howell also won in the Aster classes, and Messrs. T. Williams and Haines for Hollyhocks and Gladioli. In classes for twelve and six varieties of indoor cut flowers Mr. R. Pinnington, gardener to Mrs. Banner, Blacklow House, Roby, won with a very choice selection ; the corresponding classes for outdoor flowers falling to Mossrs. Littlemore & Moore and W. Neish, gardener to J. H. Ismay, Esq.

For a dessert table containing six distinct kinds of fruit (Pine Apple excepted), and only two bunches of Grapes, either two black or two white, or one of each colour, representing one kind of fruit, five staged, Mr. R. Pinnington winning with Muscat of Alexandria and Gros Maroc Grapes, Negro Largo Figs, Pineapple Nectarines, Crimson Galande Peaches, Best of All Melon, and Madame Treyve Pears. Ampelopsis Veitchi and Lygodium scandens were used for foliage, the flowers being Gloire de Dijon Roses and Anemone japonica alba. Mr. O. Roberts was a good second ; Mr. Ferguson, gardener to Mrs. Paterson, Rock Ferry, third ; and Mr. Stephenson, gardener to P. McGuffie, Esq., Woolton Hall, fourth.

Mr. J. Bracegirdle, gardener to W. H. Watts, Esq., Elm Hall, Wavertree, had a choice six distinct kinds of hardy fruit, comprising Irish Peach Apples, Jargonelle Pears, Negro Largo Figs, Victoria Plums, Lord Napier Nectarines, and Grosse Mignonne Peaches. Mr. Roberts was placed second. Grapes were of excellent quality, Messrs. Ferguson and G. Jackson, gardener to R. T. Richardson, Esq., being first and second, but surely the Judges scarcely gave sufficient heed to the two grand massive bunches, such as one rarely sees, fine in berry, well coloured, flavour good, and quite five times the weight. Messrs. Ranson and Ferguson had well-coloured Muscat of Alexandria, Messrs. Neish and Pinnington with Madresfield Court, and Messrs. Pinnington and H. Morris, gardener to George Atkin, Esq., with any other white. Messrs. Roberts and Stephenson took the Peach and Nectarine prizes with Sea Eagle and Pineapple. Melons went to Messrs. Downham and J. Williams. Apples were large and well formed, the winners being Messrs. J. Jefferson, P. Stephenson, S. Jones, H. Reynolds, and C. J. Waite, gardener to Sir Patrick Talbot. The Plum classes fell to Messrs. Roberts and Neish.

Vegetables are nowhere seen to greater advantage, but as varieties were many of them not labelled we simply give some of the winners—viz., Messrs. Littlemore & Moore, J. J. Brewin, Neish, J. R. Carter, C. J. Waite, Kendrick, Jefferson, O. Roberts, and H. Banks. The Tomato prizes were taken by Mr. Stephenson. Owing to the torrents of rain falling on both days there was a deficit of something like £250, but as the Society is composed of some of the great Lancashire and Cheshire magnates no doubt the adverse balance will soon be met, for the educational value of such shows cannot well be over-estimated.

GLASGOW.—September 1st and 2nd.

The Show of the Glasgow Horticultural Society was held in the St Andrew's Halls on the above dates. Probably the accommodation is the worst in the country, the halls being excessively dark, the Kent hall, where the vegetables were staged, being lighted all day by electric light. Plants are never a strong feature at Scotch shows, but the competition for tables, which take the place of the familiar groups, were well contested. Mr. D. Wilson, gardener to H. Steven, Esq., Westmount, Kelvinside, taking first place, and winning a handsome silver cup. The table contained well coloured Crotons, Carex, Cocos Weddelliana, Odontoglossum Alexandræ, and was light and elegant. Mr. H. Miller, gardener to A. Russell, Esq., Auchenraith, was second. Ferns, Pelargoniums, Palms, and other plants were shown, but call for no special notice.

Florists' flowers are always very fine at Glasgow, this year the competition being wonderfully keen throughout. For twenty-four Roses Messrs. D. & W. Croll, Dundee, were first, and Messrs. Cocker & Son, Aberdeen, were a close second. For twenty-four Gladioli Mr. Mair, Prestwick, was first, staging magnificent spikes. Mr. Smith, Prestwick, won with twelve spikes. There were six lots of twenty-four double Dahlias, Mr. Campbell, Blantyre, taking first place with fine examples, among others of Chieftain, Harry Keith, Duchess of York, Shottesham Hero, Mr. Chamberlain, Mrs. Morgan, and Cherub ; Mr. Smellie, Busby, second ; and Mr. A. Lister, Rothesay, third. For twelve sprays of Violas five competed, Mr. Campbell winning first with beautiful examples, Mr. Smellie second. Carnations were exhibited in great quantity and splendid quality. Mr. Campbell won for twenty-four, showing fine blooms of Alburea, Ladas, The Dey, Water Witch. Mr. Lister, Rothesay, second.

Marigolds are always a feature here, and the Africans were very fine on this occasion. For twelve African Marigolds Mr. Gourlay, Bishopbrigg, won, and Mr. Stewart, Lennoxtown, was second, both showing perfect flowers and of large size. For twelve bunches of herbaceous flowers Mr. Stewart was placed first, but the exhibit was rather spoiled by every flower being wired and the bunches made too stiff. If exhibitors would only stage herbaceous flowers naturally the effect would be much more beautiful. For twelve blooms of Cactus Dahlias Mr. McGregor, Kilmarnock, was first out of ten competitors, showing many of the newer varieties, Mr. Stewart second.

Fruit was well shown, especially Grapes. For a collection of twelve dishes of fruit, Mr. D. Murray, gardener to the Marquis of Ailsa, Maybole, won with a Queen Pine, Passiflora edulis, Best of All Melon, Black Hamburgh and Muscat of Alexandria Grapes as his best. For four bunches of Grapes, Mr. D. Airdrie, gardener to J. Graham, Esq., Larbert, won with Muscat Hamburgh, Black Hamburgh, Muscat of Alexandria, and Madresfield Court. Mr. J. Leslie, gardener to A. Coats, Esq., Pitcullen, Perth, was second. Mr. Airdrie was also first for two bunches of black Grapes, a collection of six dishes of fruit, and for six Peaches, the variety being Sea Eagle. For two bunches of Black Hamburgh Grapes, Mr. D. Menzies, gardener to J. Brown, Esq., Dunipace, Larbert, was first ; while for two bunches of white Grapes Mr. J. Taylor, Black Dale, Largs, took first place.

Vegetables were very fine, clean, and of good quality considering the wet, cold season experienced in the neighbourhood. For a collection of vegetables arranged in a box Mr. J. Brown, gardener to A. Spiers, Esq., Houston House, Houston, was first. Amongst others splendid Champion Leeks, Autumn Giant Cauliflowers, Winningstadt Cabbage, and Duke of Albany Peas were shown. Mr. C. Trail, gardener to Mrs. Ballantine, Killwinning, second. Mr. Brown was also first for a smaller collection of vegetables. There was great competition for six Leeks, Mr. Cole, gardener to Col. Stuart of Torrance, taking first place with fine, clean, well-blanched solid examples. Mr. J. Gilchrist, gardener to J. D. Bell, Esq., Clifton Hall, Ratho, being second. Nine lots were staged in this,

and ten in a similar class, the same exhibitor winning. For three heads of Celery Mr. Angus, gardener to Lord Hamilton of Dalziel, was first. Potatoes were exhibited in great quantity, Mr. Gemmell winning with six dishes, consisting of Supreme, Abundance, Windsor Castle, Fillbasket, Reading Russet, and Matchless. An amateur (Mr. Watson, Crosford) won in both Onion classes with Dobbie's Golden Globe.

Several trade exhibits were staged. Messrs. Smith & Simons, Glasgow, sent a table of plants; Messrs. Austin & McAslin also contributed a fine collection of plants on the platform. Mr. Forbes, Hawick, had Pentstemons and herbaceous flowers; Mr. Cuthbertson, Rothesay, herbaceous flowers and Alpine plants; Mr. Irvine, Jedburgh, fine Pentstemons; Mr. Smellie, Busby, Violas, Pansies, and Dahlias. Mr. M. Campbell, Blantyre, had a good display of annual hybrid Chrysanthemums, Carnations and Dahlias, and a new White Carnation; and Messrs. Dobbie & Co., Rothesay, a superb collection of Cactus and Pompon Dahlias, containing many novelties. No recognition is made to the trade for the splendid displays they make, and constituting one of the features of the show. The show was formally opened by Mr. A. Cross, M.P.

CRYSTAL PALACE.—September 3rd and 4th.

The annual Exhibition of the National Dahlia Society was held, as usual, at the Crystal Palace. The Exhibition was quite up to the average in all respects, the Cactus section appearing most popular with the exhibitors, as it undoubtedly was with the visitors. The single Dahlia appears to be steadily going on the downward path. The miscellaneous exhibits were numerous, and added a pleasing diversity to the rest of the exhibits.

The commemoration class for collections of Dahlias, illustrating the development of the flower during the Queen's reign, only brought forth two competitors. Mr. M. V. Seale of Sevenoaks secured first prize with a very artistic display, the Cactus varieties being very prominent, and their colours beautifully blended. The other sections were represented by Pompons, Singles, Show, and Fancy. The whole made a pleasing exhibit. Messrs. Cheal & Sons, Crawley, must have been a very close second, the exhibit being charmingly arranged. All sections of the flower were fully represented, while a good supply of Isolepis, Panicum, Asparagus plumosus nanus, Crotons, Palms, and Grasses lent loyally to the display.

Messrs. Keynes, Williams & Co., Salisbury, secured the place of honour for sixty Show and Fancy varieties with a very fine, even stand, in which the colours might have been displayed to better advantage. The best blooms were Wm. Rawlings, Emin Pasha, Matt Campbell, Virginale, Nubian, Wm. Keith, T. S. Ware, Gaiety, Duchess of Albany, Duke of Fife, Colonist, Mrs. Morgan, John Hickling, Arthur Ocock, Pelican, Kathleen, and Imperial. The second prize fell to Mr. C. Turner, Slough, whose blooms were visibly weaker than the first prize stand. The most noteworthy flowers were Geo. Rawlings, Maud Fellowes, Chieftain, Mrs. Morgan, H. Watson, Mrs. Noyes, T. J. Saltmarsh, and Duchess of York. Mr. J. Walker, Thame, Oxon, was third, and Mr. S. Mortimer, Rowledge, Farnham, fourth.

For forty-eight distinct blooms Mr. J. Walker, Thame, secured first place. The most conspicuous flowers were Maud Fellowes, Purple Prince, Miss Cannell, Peacock, Earl of Ravenswood, Harry Turner, Eclipse, and John Rawlings. Mr. C. Turner was second with a bright, clean collection. Dante, Shirley Hibberd, Mrs. C. Noyes, Wm. Keith, John Standish, T. J. Saltmarsh, Chieftain, and W. Garrett were most noteworthy. Mr. S. Mortimer was third, and Mr. M. V. Seale fourth.

In the class for thirty-six blooms, distinct, Mr. G. Humphries, Kington Langley, Chippenham, was awarded senior honours. Alice Emily, T. J. Saltmarsh, Arthur Rawlings, Glowworm, Duke of Fife, Sunset, Mrs. D. Saunders, and Harry Turner were all fine flowers. Mr. J. West, Tower Hill, Brentwood, was second with a good collection, and Mr. J. Stredwick, St. Leonard's-on-Sea, third. For twenty-four distinct blooms Mr. G. Humphries was first with a very fine exhibit. The second position was awarded to Mr. J. West, and the third to Messrs. C. Kimberley & Son, Stoke Nurseries, Coventry. For twelve blooms, distinct, Mr. J. R. Tranter was first, and Mr. A. Rawlings, Romford, second.

The Cactus varieties made a brave show, the leading classes being keenly contested. For eighteen bunches, distinct, Messrs. J. Burrell and Co., Cambridge, were placed first with a very bright and effective display, the best were Regulus, Starfish, Fusilier, Mrs. Kingsley, Foster, Chas. Woodbridge, Falka, and Mrs. Wilson Noble. Messrs. Keynes, Williams & Co. secured second place with a stand which contained some notable seedlings. Messrs. J. Cheal & Sons were third, and Mr. J. Stredwick fourth. For twelve, Mr. J. West had a very fine and effective collection. Mr. J. Humphries was second, and Mr. S. Mortimer third. The class for twelve bunches of decorative Dahlias did not bring out a very good competition. The first prize was secured by Mr. M. Seale with an effective display. Messrs. J. Cheal & Sons, and G. Charlton, Tunbridge Wells, were second and third respectively.

Pompons were largely exhibited, Messrs. Keynes, Williams were placed first for twenty-four distinct with a fresh and bright display. Little Jack, Jewel, Clarissa, Sovereign, and Agate were especially good. Messrs. J. Cheal & Sons were second, their best being Dr. Jim, Ganymede, Tommy Keith, Cecil and Orpheus. Mr. C. Turner was third. For twelve bunches Pompons, Messrs. J. Burrell & Co. were first, showing Mary Kirk, Nerissa, Bacchus, and E. F. Junger well. Mr. J. West was second with good bunches of Donovan, Gipsy, Bacchus, Emily Hopper, and Nellie Broomhead, and Mr. J. Charlton third.

The single Dahlia appears to be declining rapidly, the chief class only brought forth two competitors. Messrs. J. Cheal & Sons were first with an admirable exhibit, the most prominent were Naomi Tighe, M. C. C., Donna Casilda, Beauty's Eye, and Miss Glasscock. Mr. M. Seale's exhibit, like the foregoing, was very fresh and bright. In the amateur section the premier prize for Show and Fancy varieties went to Mr. T. Hobbs; Mr. A. Starling, gardener to H. H. Raphael, Esq., Rosecourt, Havering, was a close second, and Mr. T. Anstiss, Brill, Bucks, third. For twelve blooms, distinct, Mr. S. Cooper, Chippenham, was placed first with a very fine stand. The amateurs' exhibits of the Cactus type prove how popular they have become. In the class for twelve, Mr. W. Mist, Ightham, secured first honours with good sprays of Gloriosa, Starfish, Blanche Keith, and Miss A. Nightingale; Mr. E. Brown, gardener to C. Bowerman, Esq., Horley, Surrey, was second, and Mr. J. Hudson, Acton, third. Mr. E. Mawley, Berkhampsted, was well ahead in the class for six bunches of three flowers; Messrs. Wilkins and E. Wyatt were second and third respectively. For nine varieties, three blooms of each, Mr. Wilkins was placed first, Mr. A. H. Needs, Woking, second, and Mr. E. Brown third.

Dahlias do not lend themselves readily to vase decoration, but some of the efforts at this show were very happy ones. Miss L. Hudson was placed first with a light and delicate arrangement; Mr. W. C. Pagram second with a more diversified display; and Mrs. W. J. Smith, Romford, third. A competition of twelve Dahlias arranged for effect in a vase brought out a strong show, Mr. R. Edwards, Beechy Lees, Sevenoaks, being first, and Miss L. Hudson second.

Miscellaneous Exhibits.—Mr. J. Green, Dereham, Norfolk, sent a collection of Cactus Dahlias and Pompons, comprising all the newer varieties and many of the Dereham seedlings. The most prominent were Midnight Sun, Mrs. Arnold, Mrs. Moore, Norfolk Hero, and Green's Gem. Messrs. Carter, Page & Co., London Wall, had an extensive exhibit of Cactus varieties, flanked by Pompons and Shows, staged somewhat formally, but producing a very bright display. A collection of Asters was staged by Messrs. A. W. Young & Co., Stevenage.

A large collection of Cactus and Pompons came from Messrs. H. Cannell & Sons, Swanley, which fully maintained the credit of the firm. Leonora, Starfish, Oporto Tait, Austin Cannell, Illuminator, Charles Woodbridge, and Mrs. Montefiore were most noteworthy in the former section, while in the latter Achilles, Flo Woodland, Nerissa, Royalty, and Dr. Ranch were very noticeable. A collection of hardy flowers was staged by Mr. John Charlton, Tunbridge Wells, composed of Montbretias, Helianthemums, Aster ptarmica, Solidago altissima, and other subjects, just now at their best. Roses were splendidly shown by Messrs. W. Paul and Son, Waltham Cross, the baskets of Tea Roses being very conspicuous, the new Tea Empress Alexandra of Russia being in fine form, as were also Enchantress and Marie Van Houtte. The Acer foliage used between the baskets had a very pleasing effect. Messrs. J. Peed and Sons, Norwood, exhibited Dahlias in all sections, backed by groups of hardy flowers. A group of Begonias, Crotons, Caladiums, and Palms from Messrs. J. Laing & Sons formed an attractive feature.

ROYAL AQUARIUM.—September 7th, 8th, and 9th.

The early exhibition of the National Chrysanthemum Society was opened on the 7th and continued on the two following days. As usual, the Chrysanthemum classes were very small compared with the exhibition of Dahlias and Gladioli, the Dahlias forming the chief feature of the show. Many of the exhibitors in the Chrysanthemum classes could not have read their schedules very carefully, or they would not have staged midseason varieties in direct contradiction to the laws laid down by the Society. On the whole the exhibition forms a very good opening for the season.

Mr. Eric Such was the only exhibitor of twenty-four bunches of early flowering Chrysanthemums, and was awarded first prize for a very fine exhibit. Twelve bunches of Madame Desgrange were not largely represented, Mr. B. Calvert, gardener to Col. A. Houblon, Hallingbury Place, Bishop's Stortford, being placed first with remarkably fine flowers; Mr. Chas. Crooks, gardener to the Dowager Lady Hindlip, Droitwich, being a close second, and Mr. W. Perrin, gardener to C. W. Richardson, Esq., Sawbridgeworth, third. In the class for twelve (Mdme. Desgrange excepted) Mr. Calvert was again placed first with a fine exhibit of Gustave Wermig. Extra prizes were awarded in this class to Mr. Jas. Agate, Havant, and Mr. W. J. Godfrey, Exmouth, for exhibits of merit, but failing in the requirements of the schedule.

The entry in Pompons was decidedly weak, Mr. E. Such taking first prize with a well-developed stand, and Miss R. Debenham second place. Mr. B. Calvert scored a decided success with six triplets of G. Wermig and Mrs. Hawkins, the blooms being very fresh and bright. Miss R. Debenham, St. Albans, was placed first with twelve bunches, Lady Fitzwygram, Edith Syrat, and Edwin Rowbottom being most noteworthy; Mr. D. B. Crane, Highgate, was placed second with a creditable exhibit of smaller flowers.

The epergnes were very attractive, Mr. T. S. Williams, Ealing, securing first with a display of white, yellow, and bronze Chrysanthemums, tastefully interspersed with Asparagus Fern and coloured leaves. Mr. D. B. Crane second. Mr. A. Taylor, East Finchley, third.

Messrs. J. Burrell & Co., Cambridge, were awarded first prize for a collection of Gladioli, making a very bright exhibit, Grand Rouge, Formosa, Althea, Atlas, Ruth, Tersa, Ella, Oriental (grand), Eunice, and Rossini being especially well shown. Messrs. Harkness & Sons, Bedale, were second.

Mr. J. Walker, Thame, carried off the blue ribbon for forty-eight Show and Fancy Dahlias with a very even set. The best blooms were Shirley Hibberd, T. W. Girdlestone, Joseph Ashby, Victor, Harry Keith, Harry Walton, and Wm. Keith. Mr. S. Mortimer, Farnham, followed with a very bright stand, but visibly weaker, while Messrs. Keynes, Williams, Salisbury, were third. Mr. S. Mortimer was well ahead for thirty-six blooms, distinct, showing John Hickling, Perfection, Mrs. Mortimer, Florence Tranter, and Jas. Huntley in fine style. Mr. J. Walker proved to be a capital second with a good variety of colours. Mr. F. W. Seale, Sevenoaks, third. A very strong competition came ont in the class for twenty-four distinct varieties, Mr. G. Humphries, Chippenham, securing first honours with very even blooms, Mr. T. J. West, Brentwood, being dangerously close; Mr. J. R. Tranter, Henley-on-Thames, third.

The section devoted to the popular Cactus varieties proved, as on former occasions, to be an unusually good one. Messrs. J. Burrell & Co., Cambridge, were the victors for eighteen bunches. The stand was remarkably fresh and well provided with colours. The best bunches were Mrs. Wilson Noble, Casilda, Cycle, Mrs. A. Beck, Falka, and Starfish. Messrs. Keynes, Williams and Co., Salisbury, took second honours with smaller blooms, though they were very bright and fresh, containing many seedlings of high merit. Alfred Vasey, Britannia, Fusilier, Arachne, Fireman, and Mary Service were the strongest bunches. Mr. C. Turner, Slough, was third, being very little in arrear of the former winners. The honours for twelve bunches Cactus Dahlias were keenly contested, the class making a very fine exhibit. Mr. T. J. West, Brentwood, secured the premier honours, Fusilier, True Friend, Eileen Palissier, Island Queen, and Oaklands being especially good. Mr. Jas. Stredwick, St. Leonards, came second with a very creditable display, while Mr. G. Humphries was placed third.

The Pompon classes proved very popular with exhibitors, and a strong display was the result. Messrs. Keynes, Williams, & Co. were first, showing a fine even lot with plenty of variety; Mr. Chas. Turner second, Mr. Seale third. In the classes provided for single Dahlias the falling off so discernible at the Palace was equally apparent here, there being but two entries for twelve bunches, distinct, Mr. E. F. Such being placed first for a very fine exhibit.

Mr. H. J. Jones, Ryecroft Nursery, Lewisham, had one of his well-known groups of early flowering Chrysanthemums and Begonias, artistically arranged with Palms, Ferns, foliage Begonias, and Grasses. The Chrysanthemums were well grown, and comprised Emily Silsbury, the well-known white; Madame Desgrange, G. Wermig, and Machet White; the Begonias, both double and single, fully maintaining the reputation of the firm (silver-gilt medal). From Mr. John Green of Dereham came an attractive exhibit of Cactus and Pompon Dahlias. Mrs. Wilson Noble, Beatrice, Crimson King, Mrs. Francis Fell, Sunshine, Fusilier, Norfolk Hero, Endymion, and Royal George were most showy in the former section, while Dolly Keith, Nerissa, Douglas, Bacchus, and Lady Blanche were most conspicuous in the latter (silver-gilt medal).

A fine exhibit of early flowering Chrysanthemums was staged by Mr. W. Wells, Earlswood Nurseries, Redhill. The bunches of Madame Marie Masse, Rose Wells, Flora, Longfellow, Harvest Home, and Louis Lemaire were very fine. Gigantic blooms of Madame Gustave Henry were also staged, showing that the good opinion of this variety formed last season has not been misplaced (silver medal). Mr. E. G. Reid, Reid's Nursery, Beckenham Hill, exhibited an attractive group of Cannas (bronze medal). Messrs. H. Cannell & Sons staged a very showy group of cut Chrysanthemums. The blooms were all fresh and bright, the new white sport from Gustave Grunerwald being very fine. Others most notable were Edith Syrat, Madame C. Perier, Mrs. Hawkins, Queen of Earlies, and Madame Carmens (silver medal).

Mr. Eric Such, Maidenhead, had a large exhibit of hardy plants and Dahlias very well arranged. Fruit was represented by a fine display from Messrs. S. Spooner & Sons, consisting principally of Apples and Pears; there were fine baskets of Grenadier, Lord Suffield, Councillor, Manx Codlin, Stone's, and Bismarck represented in the former section (silver-gilt medal). Mr. T. H. Witty, Nunhead Cemetery, exhibited a very fine exhibit of early-flowering Chrysanthemums beautifully arranged with Ferns (silver-gilt medal).

RONDELETIA ANOMALA.

Persons who are possessors of a warm glass structure in their gardens might advantageously grow one or two of these handsome plants, the Rondeletias. They are free-flowering and attractive, and cultivated without difficulty in a warm temperature. Fifty degrees at night in winter should be the lowest the plants are subjected to, and a few degrees higher would be better. One of the most beautiful species is R. anomala, which is, however, somewhat scarce. A spray is shown in the engraving. It was cut from a specimen suspended on the roof of an intermediate house, and the plant was bearing numerous clusters of rich coral red or deep scarlet flowers. It was grown in a shallow pot or pan; a compost of peat, light turfy loam and sand being found to suit it admirably.

THE YOUNG GARDENERS' DOMAIN.

Malmaison Carnations.

Although for market purposes these flowers do not fetch the fancy prices they did a few years ago they are still greatly admired by most people. The varieties I have had to deal with are the Pink, Blush White, Arthur Warocque, and Lady Middleton. For general purposes the Pink variety is the best to grow. It flowers freely, is of good size, and the scent is delightful. The Blush White variety merits next place. Arthur Warocque has smaller flowers, is very prolific, and the colour is also good. Lady Middleton is a striped variety, but I have never seen it worthy of extensive cultivation.

Fig. 35 – Rondeletia anomala.

Young plants carry the better flowers; but with a number of old plants a few blooms are to be had nearly all the year round. For young stock layering ought to be commenced as soon as the plants are out of flower. It is advisable to have the layers clear of green fly at this stage. If they are clean now they take far less keeping clean afterwards. They root readily in a cold frame, where they can be shaded and kept slightly moist till rooted. They are the better for a slight shade from bright sunshine. I think it advisable to leave the young plants in the bed till they can be lifted with large balls. They may be potted into 6-inch pots, in which they will flower. After potting they may again be placed in a frame on a bed of coal ashes to raise them near the glass.

By the latter end of September the plants ought to be growing freely, and should then be removed to their winter quarters. A cool house free from drip, with stages covered with ashes, is an ideal place for them. Provision ought to be made for both top and side air, also hot-water pipes provided, so that in dull weather a little heat may be turned on. The plants enjoy a little heat at any time during the winter with plenty of air. I have never seen syringing of the plants practised, and always found the reverse successful. The ash stage has a tendency to keep the air about the plants cool and fresh. Soil for these plants ought to be of the simplest. Good fibrous loam and rough sea sand, two-thirds of the bulk being loam, with a little bonemeal or other standard fertiliser, are all that is necessary. A dusting of soot over the drainage helps to keep away worms. The pots ought to be well drained, and in potting the soil must be made firm.

The most particular point, however, in successful cultivation is in the

watering, which ought to be done very carefully. The soil should always be on the dry side, and during the winter the pots ought to ring clearly before water is given.

As the growth advances the plants ought to be repotted some time before the flower buds are developed. The very small buds take no harm, and the fresh soil at the roots puts new life into the young growths. The best plants, with most strong shoots, should be selected, preference being given to those with shoots near the base of the stem, as a long-stemmed Carnation is unsightly. During the summer months a cold, airy frame suits the plants well. Green fly is one of the worst enemies of Carnations. Fumigating occasionally keeps the insects in check. Tobacco powder dusted into the points of the growths answers very well, but some persons object to seeing it about the shoots. I have had the good fortune to have had very little to do with disease, so have nothing to say about it.

Malmaison Carnations, like most choice plants, require care and attention to grow them well, but when seen in the best condition are a credit to the cultivator and afford pleasure to all.—S., JUNIOR.

CULTURE OF THE GRAPE VINE.

(*Continued from page* 227.)

FOR early forcing small lean-to houses facing south are generally preferred, having both top and bottom ventilators. Sufficient piping should be provided in order that the required temperature may be maintained without the pipes being unduly heated. This refers to all vineries, as when the pipes are highly heated weakly growths and red spider are the result.

We were told in the *Journal of Horticulture* for July 23rd, 1891, "A house requiring a temperature of 65° during winter will need 1 foot of 4-inch piping to every 17½ cubic feet of air." If this were taken as a guide we should not be far off the mark, as the article is by an eminent authority. For succession houses, which are generally larger, either lean-to or three-quarter span-roofed structures are the best. For late Grapes span-roofed houses running north and south are the most serviceable. If possible these latter should have a lantern ventilation. Much care and trouble are taken off one's mind when Lady Downe's Grapes are stoning, if the necessary chink of air can with safety be left on the house all night. With older structures, having sliding ventilators, these have to be closed. In these cases an extra half hour in bed by the duty man often means ruin of the bunches by scalding, and in some cases costs the young man his berth.

In making Vine borders it must be taken into consideration for what purposes the Grapes are intended, whether for early or late use. If for early use the excavation for holding the compost need not be so large as for midseason or late Grapes. A border of from 5 to 6 feet inside the house, allowing the same space outside, will be quite sufficient for early forcing; while for later houses, 9 feet inside, and from 9 to 12 feet outside, will be found serviceable distances. The depth of the early border should be 2 feet, or at most 2 feet 6 inches, while 3 feet, or 3 feet 6 inches, is advisable for the later ones. The sides of the excavation should be bricked in cement the depth of the border both inside and outside the house. This will keep the roots from rambling, and under proper control. The bottom of the space must be concreted, having a slope to the drain. On the concrete small draining pipes are placed at intervals of from 8 to 10 feet, connecting with main drains running the whole length of the border. These, in their turn, must connect with a drain so made that all superfluous water may be carried away. For the drainage proper half brickbats or good sized clinkers placed on the concrete to a depth of 9 inches, with smaller pieces on the top, making a depth in all of from 15 to 18 inches, will be found a lasting provision if the drainage is protected with turves. The compost and planting must be deferred to a further article.—SEMPER.

(To be continued.)

HARDY FRUIT GARDEN.

Hints on Gathering and Storing Fruit.—*Cleansing the Fruit Room.*—In order that fruit may keep well, ripen satisfactorily, and be of good flavour, one of the conditions of success is that, when stored, the surroundings ought to be clean and sweet. Previous to gathering fruit in quantity, therefore, the receptacles in which it is finally placed, or rooms where it is stored on shelves, must have a good cleansing. Damp, dirt, cobwebs and dust are inimical to the preservation of fruit for an extended period. Scrub down all woodwork with soap, soda, and hot water, paying special attention to drawers and the interstices of latticed shelves. Walls, whether of brick, stone, or wood, may be whitewashed with fresh lime. Deal also with the floor. The structure ought to be thoroughly dry before any fruit is introduced.

When to Gather Fruit.—It requires good judgment to select fruit which is quite right for gathering. Few varieties of Apples and Pears require to hang on the trees until perfectly ripe. The majority should be picked at such time as is indicated by the brown or dark colour of the pips, or the ease with which the fruits are detached from the spurs when raised to an horizontal position. If on doing this they do not easily separate from the spurs, the fruits may be allowed to hang some time longer. It is probable they will improve in size and flavour, and will keep better when picked. Many varieties of Apples and Pears are liable to shrivel if gathered too soon. The best time to gather is when the fruit is dry and cool.

How to Gather Fruit.—The right time being selected for gathering, handle each specimen carefully, placing in single layers in a basket lined with soft material. Bruising the cells of the fruit underneath the skin causes decay to set in, preventing the fruit keeping. Similar care must be exercised in moving the fruit from the baskets to the drawers or shelves. Handle as little as possible.

Storing Fruit.—Place the fruit in single layers on clean white paper. If not stored in a proper fruit room on shelves or in drawers, boxes or detached drawers will answer well, placing one receptacle on the top of the other. It is requisite that the fruit when stored be kept cool and dark. If possible keep each variety separate, as there is a difference in the time of ripening. Some of the earliest Pears do not require much time in ripening. They will finish within a short time after being gathered and placed in a comparatively cool room. Others need a little assistance in finishing by introducing them into a slightly higher temperature for a brief period. Store Apples separately from Pears. Examine the fruit frequently, seeing that no decayed specimens are allowed to remain, for they speedily contaminate others.

Outdoor Vines.—Vines on walls or trellises require a little attention in regulating the growths, so as to expose the bunches of fruit to the light. Black varieties, however, are best for some shade of foliage, as they colour better than when exposed to unobstructed sunshine. On the other hand, white varieties need more sunshine to colour and ripen satisfactorily. The principal pruning consists in the removal of superfluous lateral growth, shortening it back so that the main growths are not crowded or shaded. Laterals bearing the bunches will need well supporting with ties, disposing them in a regular way, for with the weight of the fruit they are liable to break loose. If the soil lacks moisture the crop will be assisted by affording a liberal supply of water to the roots.

Watering Wall Trees.—Wall trees need considerable quantities of moisture at the roots during the early part of autumn. The demands of the fruit and the development of the summer growths abstract in many cases almost all the moisture from the soil. This leaves an insufficient amount to build up and perfect the buds, even after the crop of fruit has ceased to require more. The lack of moisture causes a check, with the result that red spider attacks the foliage, especially of Peaches and Nectarines, Apricots and Cherries. When the trees have been cleared of fruit an examination may be made of the borders. If they are very dry, afford clear water copiously, but to others fairly moist liquid manure may be applied. Syringe freely as an antidote to red spider. In bad cases employ also insecticide.

Strawberry Planting.—Further breadths of Strawberries may be planted now. Select well prepared ground that has been deeply cultivated and liberally manured. Strong plants of some of the best varieties should be planted, including Royal Sovereign, President, British Queen, Sir Joseph Paxton, Noble, Lord Suffield, and others. The plants must have abundance of roots if the object is to secure a crop of fruit the next season. Those established earlier yield the best crops the first season, but there is still a probability, if exceptionally good plants are inserted, that useful crops will result.

FRUIT FORCING.

Peaches and Nectarines.—*Early Forced Trees.*—The trees have now shed their leaves, and may be syringed with water at a temperature of 130°. It must not, however, be used carelessly; if too hot it will injure the trees; if lower in temperature it is useless as regards scale, red spider, thrips, and aphides. All the house should be subjected to the hot water treatment, as simple, effective, and safe for cleansing, on the score of both fungoid germs and insect pests. The trees being loosened from the trellis, and tied in small bundles for facilitating cleansing operations, wash the woodwork with a brush and disinfectant soap, reaching every angle and crevice. Limewash the walls, and, if required, paint the wood and wirework. Pruning will be a light affair, merely thinning the shoots where crowded or too weak for carrying fine fruits, no shortening being necessary except for the production of shoots for extension and furnishing the trees with bearing wood. Remove the loose surface soil down to the roots, and supply an inch or two, not more, depth of fresh loam, containing about a fourth of well decayed manure and about 7 lbs. of raw bone superphosphate and 3½ lbs. of double sulphate of potash and magnesia to each cartload. Avoid mulchings of manure at this time, they exclude air. If the roof lights have been removed they need not be replaced until the time arrives for starting the trees. Where the lights are fixed admit air to the fullest extent constantly.

Early Forced Trees in Pots.—The trees must, if not already done, be top-dressed, but it is best done before the leaves have fallen, as fresh roots are pushed at once, and this makes a difference in the setting. Roots outside the pots should be cut off, and some soil removed all round the inside of the pots about two-thirds down, supplying fresh compost there and over the roots. Give a good watering, and plunge the pots in ashes level with the rims in an open but sheltered situation till forcing time. From Alexander, Early Louise, Hale's Early, and Stirling Castle Peaches, Cardinal and Early Rivers Nectarines excellent crops may be

had very early. The pot plan is an excellent one, as it gives early dishes without having occasion to force planted-out trees at so early a period.

Second Early Forced Trees.—The trees are commencing to shed their leaves, and the lights having been removed at the end of August, the buds are well plumped and not over-matured, as occurs under fixed roofs, especially with such varieties as Early York and Noblesse. The removal of the roof lights sometimes prevents the buds falling if taken in time, but the chief cause is imperfect formation of the floral organs in embryo, and nothing will rectify that serious defect. When the leaves are all down treat the house and trees the same in every respect as the earliest house.

Succession Houses.—Any trees that have a tendency to over-luxuriance should, as soon as the wood is sufficiently firm, have a trench taken out one-third the distance from the stem the trees extend on the trellis, and quite down to the drainage, so as to detach all roots, and this may be left open for a fortnight; then the soil may be removed down to the roots, and picked from amongst them with a fork, laying in the roots in fresh material, good loam, rather stiff, being best, with about a sixth of old mortar rubbish. With a good watering, the roots will soon grow freely in the fresh material, and the fruits invariably set well afterwards. In removing the soil care must be taken not to disturb the roots so as to cause the sudden collapse of the foliage. Defer root-pruning in other cases, and also lifting, until the leaves give indications of falling. The first plan is more especially necessary with young trees, the taking out of the trench being very effectual in assisting the wood to ripen thoroughly, but the method is more applicable to older trees strong in growth or not satisfactory in ripening the wood and in cropping, whilst weakly trees should have the roots carefully brought nearer the surface, and fresh soil given in order to secure a more nourishing medium.

Late Houses.—Late Peaches are remarkable for size and beauty, and if given due supplies of water and nourishment during the swelling period are excellent in flavour. When kept too warm and dry the fruit is apt to be deficient in juice, or mealy. A free circulation of air is necessary, utilising sun heat if the fruit is backward, as with ventilation in the early part of the day the temperature may rise to 85° or 90°, which is of infinitely more value than fire heat at a later period. Afford the trees sufficient water at the roots to prevent the foliage becoming limp, but a rather drier condition is advisable when the fruit is ripening. Keep the wood thin, stop any growing shoot to about 15 inches, and all laterals closely to one joint as growth is made.

Vines.—*Young Vines.*—Give every encouragement towards keeping the foliage clean, removing all laterals so far as can be done without starting the pruning buds, as growth produced after this period is of comparatively little value, and maintain a warm well-ventilated atmosphere until the canes are ripe. The ripening of the wood may be accelerated by keeping the house rather close in the day, so as to secure a temperature of 85° or 90° from sun heat, opening the ventilators at night. Any supernumeraries intended to fruit next season should have the laterals cut away to the principal buds, leaving, however, an outlet for any excess of sap by a few laterals at the top of the cane, and be careful not to injure the principal leaves.

Late Houses of Hamburghs.—The Grapes which embrace the thin-skinned varieties generally, not Muscats, are well advanced in colour and ripening. A gentle warmth in the hot-water pipes is necessary so as to admit a free circulation of air and to maintain the temperature at 60° to 65° at night and 70° to 75° by day, as a little artificial heat during the day materially benefits in allowing free ventilation and making the most of sun heat. Hamburghs finish better under a good spread of foliage, and retain the colour longer, but it is well not to encourage lateral growth now; at the same time, the tendency to shanking is accelerated by large reductions of foliage, and equally so by sudden fluctuations of temperature. A little air may be admitted at the top and bottom until the Grapes are ripe. If there is any deficiency of moisture in the borders it will be better to give a supply of water now than to delay it until a later period, covering with a little dry material to prevent damp rising. Outside borders will, in most instances, be sufficiently moist; if not, they must be watered, and unless the weather becomes wet they need not be covered at present; but spare lights may be used in case of heavy rains, as a saturated state of the soil certainly does not favour the Grapes hanging in good condition. Over-dryness, on the other hand, causes the berries to shrivel.

Late Houses.—Muscats, especially Muscat of Alexandria and other white varieties, colour best with the foliage rather thin; indeed, the leaves may be tied aside, as it is necessary the Grapes have abundance of light and air. Other late Grapes still require fire heat, as they are late this season, accompanied with a free circulation of air, continuing it until they are thoroughly finished. Keep the night temperature at 65° to 70°, with a fall of 5° through the night, and turn the heat on in good time in the morning so as to allow an increase of ventilation and the temperature to be raised to 70° to 75°, so as to secure for the Grapes a long ripening day, the temperature being kept at 80° to 85° from sun, and with a free circulation of air 90° to 95°. The heat should be kept up by reducing the ventilation with the declining sun, and the temperature allowed to gradually decline at night, only keeping warmth in the pipes to allow the top and bottom ventilators to be left open to a slight extent so as to insure a circulation of air, and prevent the deposition of moisture on the berries during the night. Do not allow the border, especially inside, to become dry. A temperature of 50° to 55° is necessary for keeping Muscat Grapes in good condition after they are ripe, and other houses of late thick-skinned Grapes will require a similar temperature for the benefit of the Vines.

THE BEE-KEEPER.

Marketing Honey.

The difficulty many bee-keepers have to contend with is the finding of a suitable market for their produce, where satisfactory prices may be obtained to enable them, taking one year with another, to have something left after paying all out-of-pocket expenses. Unfortunately the greatest sufferers are those who have only a few stocks of bees, while the bee-keeper who has a large apiary will often dispose of hundredweights of honey with little trouble. The reason is not far to seek. The man who has invested his capital in the undertaking must take steps to find out the best market for the particular goods he deals in, and when he has obtained a good customer supply him with a good article.

The days of big prices are gone, but probably owing to so many unfavourable seasons there has been little change in the price of honey during the past few years. There are doubtless hundredweights now sold where as many pounds were obtained a quarter of a century ago. It is always advisable to cultivate a local demand for honey, and it is surprising the quantity that may sometimes be distributed locally by making it known. Better prices may be obtained in this manner, there being less expense than when sending it long distances.

For retailing purposes I prefer the 1 lb. screw-top glass jars, and as they may be obtained from the English manufacturer at a reasonable price, these are better than the tie-over glass jars, the covers of which soon become discoloured when exposed to the dust and flies; and as dealers and consumers prefer the former, they cannot be too highly recommended. Honey, of good quality, when placed on the market in these packages, has a neat appearance, and if labelled with the producer's own label, it is a mark of genuineness, and a help to future sales.

Grading Honey.

There is a vast difference between samples of honey obtained from various sources; I will name a few of the most prominent. Honey obtained from fruit trees has a greenish tinge, and does not granulate so readily as some varieties. From field Beans, which usually follow, it is of good flavour, brown in colour, but rather coarse in the grain. This is more readily observed when granulation has taken place. Mustard produces a white honey of poor flavour, and which granulates readily, often before it has been stored many days. Next comes the cream of all honey, that obtained from the White Clover. It is of exquisite flavour, very light in colour, and when granulated fine in the grain. This is closely followed by that obtained from the Lime trees, which is of a bright golden colour, and good in flavour. In many districts bees have not an opportunity of working on the Limes, as in some parts of the country one may go for miles and not see a Lime tree. In other districts they are very plentiful; within a mile of my apiary there are hundreds of large trees which form a veritable paradise for the bees.

It is advisable to keep each sample of honey separate so far as is possible. This is not nearly so difficult as may appear at first sight, if the bees are worked on the doubling system. All that is necessary is each time it is extracted to keep it separate from what is obtained on the next occasion. This only refers to extracted honey; sections must be left to chance, as it matters but little whether it is mixed or not in the comb.

I do not advocate the system of mixing light and dark honey together with a view to improving the latter, as it would most certainly spoil the former. If kept separate each sample can then be disposed of on its merits. Or if required for home consumption it is interesting to observe the difference existing between the various samples of honey.

Packing Honey.

This is important, as it is useless obtaining a good sample of honey in quantity unless the producer knows how to pack his produce, whether in jars or sections, so that it may travel long distances without danger of being smashed in transit. For large quantities of run honey the patent self-opening tins answer admirably. It is not safe to send them by rail without being packed in boxes. If some wads of hay or straw are placed firmly between them they may be sent long distances without any danger of mishap. In packing run honey in 1 lb. glass jars it is an advantage if a box is divided with laths, so that squares are formed into which a jar is dropped. Boxes made to hold two dozen are a convenient size, and without dividing them with laths they will travel safely if a stout roll of paper is bound round each bottle and packed firmly, care being taken that they are well padded with hay round the sides, so that there is no chance of their shaking loose. They should be labelled "Glass, with care," and may be sent by goods train.—An English Bee-keeper.

TO CORRESPONDENTS

*** All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, *Rose Hill Road, Wandsworth, London, S.W.*, and *not* to Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Trimming Strawberry Plants (*Strawberry*).—When cutting away the runners of Strawberry plants in the ordinary way after fruiting, it is desirable to leave the perfectly healthy foliage of the old plants untouched, but no injurious effect is caused by cutting away the decayed, unhealthy, or imperfect bottom leaves. These are better removed, though not ruthlessly torn off in a manner we have often seen, but which is not likely to occur under your thoughtful supervision.

Membership of the Royal Horticultural Society (*W. H., Natal*).—Anyone interested in horticulture may become a Fellow of the Royal Horticultural Society. It is necessary to be proposed by a Fellow and to be seconded by another. The benefits that accrue to Fellows are numerous, amongst the chief of which are admissions to all the shows of the Society at the Drill Hall or elsewhere; to send seeds, bulbs, or plants to Chiswick for trial; to a share in the distribution of plants, and most important of all, in your case, to copies of the Journals of Royal Horticultural Society as published. These contain the papers that have been read at meetings, and are always interesting and instructive. There may be other benefits that you may secure for a guinea annual subscription, but these will suffice to give you a rough idea. We trust you will soon become a F.R.H.S., as it would be well if every gardener and horticulturist were one.

Watering Cattleyas (*F. W. D. R.*). — Water should be withheld gradually from these plants, beginning to do so as soon as the pseudo-bulbs are fully developed and display signs of ripening, and finally given only sufficiently often to keep the pseudo-bulbs from shrivelling. How long water can be withheld depends largely upon the house in which the plants are grown and the atmospheric conditions maintained as regards moisture. Simultaneously with a diminished supply of water at the roots and moisture in the atmosphere more light and air should be admitted to the plants. The Oncidiums you mention are only of slow growth; they do not under the best systems of culture appear to increase materially in size. We prefer to grow them in small baskets or pans, because they are less liable to suffer by an insufficient supply of water during the season of growth. If you place the plants in baskets do not take them off the blocks, but insert them into the baskets and fill in with fibry peat and charcoal in lumps. A little moss during the season of growth is also an advantage. We should advise you to leave them as they are until the spring. By no means should too much peat and moss be placed about the roots. These plants do best suspended moderately close to the glass.

Rose Cuttings (*Novice*).—If cuttings of half-ripened wood are taken off with the foliage attached, cut into lengths of two or three joints, and inserted in sandy soil before they flag, nearly every one of some kinds will root. The cuttings should be inserted in hand-lights placed in a shady position, and the top eye only left above the soil. After insertion a good watering should be given, and the hand-lights kept as airtight as possible. In about a month they will be well rooted, and may be carefully lifted and placed singly into 4-inch pots. If encouraged to grow under glass afterwards they will become well established before the winter, and will make excellent plants the following season, whether they are planted out or kept in pots. Such kinds as Gloire de Dijon, William Allen Richardson, and others of similar growth will, if well grown under glass the following season and placed as they need it into 8 and 10-inch pots, make good plants for forcing the following spring. Nearly all Tea Roses do well grown in pots, which is advisable if required for flowering under glass. Hybrid Perpetuals do better, and make greater progress if planted out in the spring in deeply dug and liberally manured ground. Many Teas and Hybrid Teas grown under glass the whole of the first season will give a bountiful supply of blooms in the autumn, when they are scarce outside, and often prove as valuable as if produced during the spring months.

Dicksonia antarctica (*A. F.*).—The plant may safely be moved, just as growth starts in the spring being a good time; but with care they may be successfully transplanted now. Plants in rockwork usually move with a compact mass of roots. With these placed in firm soil, kept duly moist, and the stem syringed, the plant will suffer little from the removal. We have found such plants improve after removal because of new roots having fresh compost to ramify in. We have also known plants cut off at any desired point above ground, and the stems well and firmly inserted in good soil, grow freely and satisfactorily.

Nutmeg (*One of the Domain*).—The note herewith and the accompanying illustration will probably give you all the information you require. The Nutmeg tree, Myristica moschata, syn. M. aromatica, is of considerable commercial importance, the kernel being indispensable for certain culinary purposes. It is also ornamental by its clusters of berries or fruit. The plant is not commonly met with in this country, and it is seldom grown except in botanical or officinal collections. Its cultivation, however, is not difficult. It thrives in a sandy loam and brisk heat, and

FIG. 36.—THE NUTMEG.

cuttings strike freely inserted in sand and placed in heat under a bell-glass. Of the Nutmeg tree Dr. Hogg has written as follows in his "Vegetable Kingdom":—"It is a native of the Moluccas and neighbouring islands, but is now cultivated in Java, Sumatra, Penang, the Isle of Bourbon, Mauritius, and other parts of the East, and in Cayenne, Martinique, and some of the West India islands. It attains the height of 30 feet, with a straight stem and a branching head. The leaves are oblong-oval, glossy on the upper surface and whitish beneath, and with an aromatic taste. The flowers are male and female on different trees, insignificant, and of a yellowish colour. The fruit is round or oval, about the size of a small Peach, with a smooth surface, green at first, but becoming yellow when ripe. The external covering, which may be called a husk, is thick and fleshy, containing an austere astringent juice; becoming dry by maturity, it opens in two valves, and discovers the nut covered with its aril, or mace, which is of a beautiful blood-red colour; beneath the mace is a brown shining shell, containing the kernel or Nutmeg. A plantation of Nutmeg trees is always made from seed, and it is not till the eighth or ninth year that the trees produce flowers. The sexes being on different trees, after the plants are two years old they are all headed down and grafted with scions taken from the female tree, reserving only one male stock for fecundation. The natives of the Moluccas gather the fruit by hand, strip off and reject the pulpy husk, detach the mace carefully, and expose it to the sun, which soon changes its beautiful blood-red colour to a light brown; it is then sprinkled with sea water to render it flexible and preserve it. The nuts are first sun-dried and then smoked, until the kernels rattle against the shell. This shell being removed, the kernels are dipped twice or thrice in lime water, laid in heaps for two or three days, wiped, and packed in bales or barrels. The unripe fruit of the Nutmeg is frequently preserved in sugar in the East, and before doing so it is necessary to deprive it of its acrid properties by soaking it in spirits."

Ants on Fruit Trees (*J. V. C.*).—Ants are best extirpated by poison, and the arsenical solution given below is efficacious. It is, however, extremely dangerous, and must be used with the utmost caution, as it is fatal to animal life. Place 1 oz. of ordinary arsenic in an old iron pot with a quart of water, and boil gently until it is reduced to about a pint, a little more rather than less, and to this liquid add half a pound of Demerara sugar, which will form a syrup. A little of this should be placed in saucers in the run, around the nests or haunts of the ants.

Eucomis punctata (*H. G. H.*).—This is a Cape of Good Hope bulbous plant, and was introduced to this country in 1783. It is easily cultivated, growing well in sound loam kept porous with crushed charcoal and pressed down firmly. After flowering the plants may be stood in a sunny position in the open air, giving adequate support for producing good foliage. Allowing seeds to ripen has a weakening tendency. Reduce the supply of water as the foliage ripens, and keep the soil dry, but not dust dry, in winter in a frame or cool house from which frost is excluded. In the spring abundance of light is needed by the growing plants, with adequate supplies of water for their support. We have had plants established in a narrow border in the open air for years next the south wall of a greenhouse. The bulbs are nearly a foot deep, and the border is mulched with manure on the approach of winter.

Pear Tree Blister Moth (*M. H.*).—The moth is minute and active, body satiny white, the wings having an orange ground spotted with black and other colours. It appears in May, and after pairing the female deposits her eggs at the end of that month or beginning of June, or later, in the tissue of the leaves on the upper surface, and from these issue the grubs or caterpillars, which feed beneath the epidermis, and produce dark brown blisters, corresponding to the spread of the caterpillar. Sometimes the blisters run together. When the caterpillar is full fed, which usually takes place in August or September, it eats its way out, and entering a crevice in the bark or a wall, where it will be snug and dry, it spins a white silken cocoon, very beautiful, and becomes a chrysalis inside, being quite small in itself, but easily recognisable by the silvery coating. From this it appears as the moth at the time before named.

Iris Leaves Diseased (*Inquirer*).—The leaves, carefully secured with wet moss at their cut ends, and in excellent condition for examination, but without a line in regard to them, were infested with spot fungus (Heterosporium typhorum) of the narrow-leaved club-rush (Typha angustifolia), the spots being very conspicuous, and exceedingly fine specimens of the parasite borne on the surface. The action of the fungus is wholly endophytic, the mycelial hyphæ traversing the tissues of the host, destroying the cells, so that the leaf or leaves attacked become yellow, afterwards brown or black, and dead. The spots clearly indicate where the fungus has entered the tissues by the germ-tube from the spore. To prevent these entering, spraying with sulphide of potassium, $\frac{1}{2}$ oz. to a gallon of water, has been found useful; but treatment with Bordeaux mixture only proves effective in bad cases. Cut off the worst infested leave and burn them, spraying the remainder of the plant or plants with either of the above or permanganate of potash, 1 oz. to a gallon of water.

Trapping Woodlice (*New Reader*).—1, Procure some old half-rotten boards, cut them into lengths of a foot to 18 inches, place on damp ground, and when fairly moist place one of these boards on the floor or other part of the greenhouse where woodlice frequent, sprinkle a little oatmeal on its upper surface, and place another board on the first. If the boards are warped so as to admit the animals between them the bait is perfect, if not introduce a small stone at one end of the boards between them. Examine these baits every morning, and either brush the captured crustaceans into a pail of hot water or cast them before fowls. These relish them immensely for breakfast. 2, Wrap a boiled Potato in a little hay loosely, put in a small flower-pot not very tightly, lay the pot on its side where the woodlice visit, and shake those which are caught out of the hay every morning into boiling water. Persevere with either of these methods, and you will soon make the woodlice scarce in your greenhouse.

Names of Fruits. — *Notice.* — We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. *In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing.* The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. *They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state.* (*Pomme*).—Possibly Cellini. (*J. A. A.*).—The Apple is Lady Henniker and the Pear Beurré d'Amanlis. (*L. C. R.*).—1, Yellow Magnum Bonum; 2, Pond's Seedling; 3, Grand Duke. (*L. E. H.*).—1, Devonshire Quarrenden; 2, Lady Sudeley; 3, Duchess of Oldenburg; 4, Miller's Seedling; 5, Worcester Pearmain; 6, unknown, probably a local seedling.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*A. B. C.*).—1, Begonia Evansiana; 2, Cratægus coccineus; 3, Berberis vulgaris. (*C. C. A.*).—1, Thunbergia alata; 2, Lonicera brachypoda aurea reticulata; 3, dead. (*Inquirer*).—1, Polygonum cuspidatum; 2, Matricaria inodora plenissima; 3, Aconitum napellus var.; 4, Achillea ptarmica fl.-pl. The Pearl; 5, Campanula glomerata; 6, Chrysanthemum indicum var. (*R. P., Braintree*).—Colutea arboreseens, or Bladder Senna, described in our issue of August 19th. (*W. W.*).—Kindly favour with fresh specimen, as we have not recognised the plant from the one sent.

A RETROSPECT AND A FORECAST.

Harvest home marks an epoch in the farming year. To some it means the fruition of a year's work and hopes, as where the crops have been well secured in the purely corn-growing counties; to others, where mixed farming is the prevailing system, it is only the half-way house. Whilst as a corn grower the farmer who is fortunate may be happy in the possession of a well filled stackyard, with a promise of good prices for his produce; as a sheep-breeder and stock-raiser he may be filled with anxiety as to the health and well-being of his lambs, and the possibility, or otherwise, of wintering his cattle successfully with only half a crop of roots.

Looking back on the past six months, we can see much to be thankful for, and we think that, on the whole, things have not gone so badly with the average farmer. The great drawback was a bad start in the spring, for there was not sufficient frost during the winter to leave the soil in that finely pulverised condition, which is such an important factor in the successful growth of either Barley, Potatoes, or Turnips. Still, matters might have been worse, and rain in March helped in the reduction of much rough clod to a crumbly mould. May was dry, as for everything except pastures it should be; June was moist, which, again, was favourable to everything except haymaking, and not very harmful to that. There is an old saying "A dry May and a dripping June, can soon put everything in tune."

July, a very dry month, was splendid for the main crop of haymaking, and for the cereals generally, but too dry for Barley on burning soils. Early Turnips suffered as the drought came, just at the stage at which they required moisture. The second week of July is the time for a good douche for the maincrop Potatoes; by this we mean the later kinds. A thorough soaking then keeps them growing until there is no fear of a premature check, or of supertuberation. This year, unfortunately, Potatoes did not receive this watering until well into August, therefore on all but the coolest soils the recent rains have induced a second growth, partially spoiling the quality of the crop already in the ground, and though the bulk may be largely increased, the later growth will hardly have time to develop good sized tubers, whilst those of the first growth will have been spoiled by the second. The rain came too late for large quantities of Potatoes, and we hear of late varieties having suffered, beyond hope of resuscitation, through lack of moisture

A dry season generally means abundance of Potatoes of excellent quality; but since the extension of Potato growing in light land districts, much of the older Potato land has been put to other crops. It is this kind of land, deep and cool, that would have just suited the Potato this year, and might have done much to make up deficiencies elsewhere, on which the Potato crop is looked for almost in vain. In Cambridgeshire and South Lincoln, a typical Potato country, Potato fields are few and far between, Barley having been largely sown instead. Twenty years ago a dry season spelt cheap Potatoes. Have the times so changed that we may experience the very opposite? It is hard to believe, but quite possible that it may be so; at any rate, crops are almost universally light.

Pastures, which were poor and bare in May, improved greatly under the influence of a dripping June, and July came in with a good bite; but this soon disappeared, and by the beginning of August the fields were brown and short of herbage. Roast meat for animals we thoroughly believe in, but there must be a fair meal, and we fear that many animals have gone on short commons during the last month. Clover and Grass are now making rapid growth, but they are too washy to be of much value as food; they will be of more use to give sheep a change off Turnips, and to eke out the latter crop, than for use at the present time.

The Turnip crop is likely to be much below the average, in many fields the young plants having only just made an appearance; but hay, though not very large in bulk, is of excellent quality, and wonderfully well secured. We incline to the belief that winter keeping will not be over-plentiful, and that store stock will not see higher prices this side Candlemas.

WORK ON THE HOME FARM.

What wonderful weather we had last week! heavy rain to put fresh life into root crops and pastures, with high winds to dry the corn quickly and so prevent damage to the harvest in those districts that were so favoured. It is mostly safely housed in the South and Midlands, but we regret to hear that in the North and in Scotland much damage has been sustained.

Turnips were very much threatened with mildew, but the rain has removed all danger for the present, though a dry September might revive it. The crop varies very much, but will be much below the average as a whole.

Thatching is the work that presses in many localities now. There is great satisfaction in seeing the corn all safely stacked, but it is not really safe until it is properly thatched; and not until this operation is completed, can harvest be looked upon as finished.

Lambs are now requiring a variety of good mature food. Well-hearted Cabbage is an excellent diet for them at the present time, and Thousand-headed Kale the next best thing; either kind provides a capital education for Turnip eating when the Turnip shall be the only staple food available. The early sown Turnips have, this season, suffered much from the drought, and have finished growing prematurely; they are very woody, and we fear will not be very digestible.

Linseed cake proved excellent for lambs during the dry time, but now that they are obliged to take to more watery food something more astringent is advisable. The better class lamb-foods mixed and supplied by leading agricultural merchants are most of them suitable for use under present conditions, and if tried will be found satisfactory.

The rain has been sufficient to allow of the cultivation of Wheat stubbles, and those with any rubbish in them had better be moved at once, when the ground and weather are favourable for the work.

Twitchy stubbles are often kept *in statu quo* too long for the sake of a bit of sheep food; but it is bad policy, for the grazing can be worth little more than 5s. per acre, if as much, and the loss of the autumn fallow may cause an after expenditure much greater than that; besides, there is the risk of not getting the land properly cleaned at all.

OUR LETTER BOX.

Sheep (*Ignoramus*). - Unless you are anxious to get practical knowledge of sheep keeping, we should not advise you to buy lambs to graze in your very small meadow. To begin with, at the most you could only feed five, and it is absolutely necessary for lambs at this time of year to have a wide range if they are to be kept in health at all. They would be almost certain to go wrong, even with the addition of artificial food. Your best plan would be to let the eatage of your field to some neighbour. The present price of lambs is from £1 to 30s. As to danger from fly, no careful shepherd ever allows flies to get any hold on sheep he may have to manage; and if you have read former numbers of this Journal, you will observe we invariably insist on bought sheep being dipped at once, and carefully watched. Scab, alas! is prevalent at all times of the year.

REMARKS.

29th.—Dull and misty, with spots of rain at times and showers after 8.30 P.M.

30th.—Rain at 1 A.M.; generally sunny after 9 A.M., but spots of rain between 1 P.M. and 3 P.M

31st.—Rain in small hours; sunny morning; frequent heavy showers in afternoon, with thunder.

1st.—Overcast early; almost incessant rain from 11 A.M., and a storm rain at 8 P.M.

2nd.—Overcast with high wind in morning; rain from 0.30 P.M. to 2 P.M., then sunny and heavy rain with thunder and lightning from 5.30 P.M. to 7 P.M.

3rd.—Fine and sunny throughout.

4th.—Fair morning and shower at 11 A.M., sunny afternoon.

A very rough week with much rain, but bright sun at times. Temperature a little below the average.—G. J. Symons.

Journal of Horticulture.
THURSDAY, SEPTEMBER 16, 1897.

THE JOURNAL OF HORTICULTURE *can be obtained from the Office*, 171, *Fleet Street, London, post free for a Quarter*, 3*s.* 9*d.* Editorial Communications must be addressed to 8, Rose Hill Road, Wandsworth, S.W.

THE BULB SEASON.

BULBS seem to be in the ascendant just now. We see them in seedsmen's windows almost everywhere ; in sacks, in bags, in boxes, in the establishments of vendors large and small, in catalogues, and in advertisements. The demand must be enormous, and it may be presumed the supply is generally equal to it, though it is pretty well known to those intimate with the trade that some kinds and varieties are apt to run out long before the season is over. This suggests that those purchasers who order what they require the soonest have not only the best choice of varieties, but the best chances of securing the soundest samples, or in other words, the best value for money.

Of all the varied practices which people of various tastes and fancies indulge in, surely none is more fallacious than waiting till the spring before procuring bulbs that should be potted and planted in the autumn. Apart from the fact of the best going first in variety, substance, and quality, even the finest samples deteriorate by being kept unduly long out of the ground. This is the case with thousands every spring which are sold in general shops, on stalls in markets, and on barrows in the streets. These are in most cases culls and refuse, unsaleable to men who know what they are buying, and dear at almost any price.

Soft, shrunken, dried, and exhausted bulbs planted too late may or may not flower in a miserable sort of way once. Tens of thousands fail even in this, and those which have strength to produce puny stems and attenuated flowers perish in the attempt, or, in other words, they make no new bulbs for producing flowers in the following season and subsequent years. This is a most important matter where it is desired to establish them permanently in grass or other positions in gardens ; and even bulbs which are grown and flowered in pots, if reasonably treated afterwards for the production and maturation of good leaves, are in better condition for outdoor planting in the following autumn than is much of the cheap rubbish by which so many persons are deluded into buying late in the spring.

Most of those vendors of bulbs who have acquired well deserved reputations are those who purchase

early of the first grade samples, and then do all in their power to effect early sales; that is, during the autumn in preference to late in the spring, even though they may have the best of means for retardation, or retaining the vitality in the bulbs to the longest possible date. If purchasers, as a body, understood the nature of bulbs as well as experienced vendors do, they would take steps to procure what they intend to grow as soon as they can be supplied.

Both in private gardens and public parks, where displays of bulbs are so magnificent, the requisite kinds and quantities are ordered in the summer for delivery as soon as ready. If this were not so there could be no such massive Hyacinths, glorious beds of Tulips, bold, strong, and lasting Daffodils, as well as the lowlier kinds, such as the sparkling Winter Aconites, pearly Snowdrops, and Crocuses in varied hues, as are annually produced. It does not follow that because they are obtained early they are planted at once. The positions may not be at liberty for them, or beds and borders prepared. But beyond all question it is of enormous advantage to have the bulbs in hand ready for planting on occasions when the soil and weather are in the best condition for their reception.

The importance of having whatever may be needed in the way of bulbs, seeds, or any other garden requisites in advance of the time when they are wanted for planting, sowing, or using does not appear to be by any means fully recognised. The habit of not ordering things till they are actually wanted, and then chafing because they do not come by return of post or the first express train, is a thoroughly bad one. That vendors do all in their power to clear off orders quickly goes without saying, but they cannot do impossibilities. The delay, which might be so easily averted by earlier action, has in hundreds of instances resulted in lost opportunities, the consequence of adverse weather changes, for which there could be no subsequent compensation.

Not a penny is saved by such delays that are so prevalent in obtaining what might be had a month sooner. The amount is the same in both instances, but the results are very different, and all in favour of those of the early bird order. In nothing is this more apparent than in the provision of bulbs. Hundreds of practical men must know that this is so, but a large number of them cannot obtain just what they want and just when they like.

All who desire to have bulbs in the fullest strength and greatest beauty in their conservatories, homes, and gardens—bulbs, moreover, which under favourable conditions will increase and multiply, will do the best for themselves by looking out for supplies without any delay at this season. There is plenty of choice, and those who have stocks, by the excellence of which they are willing to be judged, take care to make the fact known, for the advantage of those who are as prudent as themselves in securing a share of the first and the best consignments of the year.

Naturally those particular kinds that are required for producing a supply of flowers as soon as they are obtainable are potted or planted the first—the planting in this case having reference to growing them in boxes for affording flowers as bright and pure as the heart could desire for cutting. If it could be ascertained how many millions of Roman Hyacinths, Duc Van Thol Tulips, and Daffodils are grown and flowered in boxes 3 inches deep and less, the bulbs packed closely together, the world would be startled. Such flowers are indispensable at and before Christmas, and for having them then, action must be taken now. The pure, fragrant, cheap Roman Hyacinths in particular should not be overlooked.

Than the various kinds of popular winter and spring flowering bulbs no plants are so easy to grow, none so certain to yield up their beauty, none which display their varied charms at a time when they are more welcome, none more accommodating or more adaptable for various positions. Surely they are worthy of the best chance that can be afforded them and of prominent attention. Bulbs have had a long rest now, so apparently have their admirers, who might if they would give of their experience as to selection, association, and cultivation for the production of sweetness and beauty in the purest forms during winter and spring.

NATURAL VERSUS ARTIFICIAL FERTILISERS.

BEING old enough to remember when artificial manures were almost unknown in gardens, sole reliance being placed on natural fertilisers, and having also tried most of the "artificials," a few remarks on the relative uses of the two in supplying food to useful crops may not be unacceptable to some of the numerous readers of the *Journal of Horticulture* at the present time.

By the term "natural" manure is meant any and every substance of a vegetable or animal nature not wholly resolved by decay and change into chemical elements or compounds with metals or non-metals, and to all intents and purposes unconverted into inorganic matter; or, in other words, still more or less organic in composition, and yielding nitrogen in the form of ammonia, the process of decomposition not being artificially accelerated, but effected by natural or cultural agency.

In contradistinction, an "artificial" fertiliser is prepared by various processes, chemical or otherwise. Thus, bones, half-inch and quarter-inch, and meal, dried blood, rape cake, fishmeal, Peruvian and Ichaboe guano, soot, and even beef and meat guanos; also the residue of bats and embalmed Egyptian cats, rank as artificial manures. All, however, including horns and hoofs, with every organic substance not chemically treated, but used in the natural form, contain organic matter, which in process of further decay evolve ammonia, and in presence of lime or some other base passes by the action of certain micro-organisms, feeding thereon—showing its organic nature—into nitr*ite* and finally into nitr*ate*.

In "natural" manure, in the form of both vegetable and animal substances, there exists a judicious blending of organic—nitrogenic—with the inorganic—mineral—elements, and on similar lines available as food as by the artificial process, only the course is much slower. No treatment adds to, but takes from, the organic substance. "Natural" bones contain from 3·57 to 4·11 per cent. of nitrogen; artificially dissolved bones contain from 1·66 to 2·86 of nitrogen; and mineral superphosphate not any nitrogen. A whole bone takes longer in decaying than a crushed one, half-inch bones last longer than quarter-inch, and bonemeal yields both ammonia and phosphoric acid more slowly than vitriolised bones, while these are less quickly acting than mineral superphosphate. The nearer, therefore, to the inorganic the speedier the action of the manure. Nitrogen, as ammonia in sulphate of ammonia, acts less promptly than nitrate in nitrate of potash and soda.

The "artificial" manure, therefore, means a supply of plant food in its quickly available form—inorganic, or finally reduced state. The natural fertiliser, on the other hand, implies a comparatively and relatively slow and, according to some, uncertain amount of nourishment. The process, however, as regards the conversion of organic matter, remains the same. It must pass by decay into ammonia, and even when combined with some base by chemical process, some time must elapse before the plant can take it into its system.

In fresh stable or farmyard manure the ammonia comes out first, then the potash, and afterwards the lime and phosphoric acid. The ammonia signifies growth—and potash, in less degree the same thing; lime represents the bonding together of the parts, quickened by sulphur; and the phosphate or phosphoric acid—the grand secret of Nature—the formation of the seed; with attendant magnesia, for perpetuation or continuance. It is all very simple, a plain thing merely requiring to be looked into and learned practically. No books, no lectures, no articles can teach practice. They can only point the way. It is a question of work, the old-fashioned gardener's principle of "proving all things." Then he knows what he is about, not before, as for instance:—

The cultivator from time immemorial had preference for thoroughly decayed manure, and for good practical reasons, and in recent years, thanks to the chemist, proved sound in principle. In fresh manure—I mean a blend of various excretæ—the organic matter stands at 246·0 parts per thousand, and the nitrogen at 4 5. Half-decayed, with its 192·0 of organic matter, affords 5·0 of nitrogen. The thoroughly rotted containing but 145·0 of organic substance, possesses 5·8 of nitrogen. The first is raw and unavailable, the second has both available nitrogen and potash, and the third has all things fit, or as near as they need be for the use of plants.

The old-fashioned gardener was not so far behind the times as some "up to date" present-day savants attempt to make out. Indeed, the blend of the old gardener—his prime, sweet, "natural" manure—forms the standard of the "artificial" fertiliser—food in available form to a considerable extent, with some in store, most in the "natural," very little in the "artificial." The first lasts beyond the first year and on to the fourth, if indeed it ever loses fertilising or mechanical value, but the latter disappears with and in the crop.

According, however, to present "advanced" ideas it must be wrong to employ a horse and cart to put on twelve to twenty loads of farmyard manure per acre when the same thing in crops can be had by using as many stones, easily carried on the strewer's back, thus

saving a horse and cart, and doing the thing in a third of the time by artificial manure. In brief, "natural" manures are characterised as delusions, and mark the era of retrogression in agriculture. It has not done so in horticulture, for it has produced "stuff" better and cheaper and lives. That is the crucial test of men and methods, and the weight of evidence conclusively shows that where there has been a departure from the old well-proved sound practices the cultivator has gone deeper into the slough of depression; on the other hand, where old methods have been adhered to, with a fair admixture of improved principles, the evil times have fallen with least malignity. The only really thriving cultivators are those who use "muck"—the workers near towns, who grasp the "fat of the land," sold off it in straw, hay, beef, mutton, pork, fowl, eggs, butter, and placed in the land again as town manure or native guano—old methods by which every description of crop is grown well.

If we go back half a century—say to before the advent of the Potato disease in 1844, and the famine produced by it, which I well remember, as a "bite" was then difficult to come at by a poor man—the gardener's sheet-anchor in the way of manure was thoroughly decayed stable refuse. Farmyard manure was held too precious to be trusted anywhere but on meadow or arable land. The gardener never let a forkful of stable manure pass over to the farm if he could keep it. Both farmer and gardener had "muck" on the "brain."

Beyond soot and Peruvian guano few gardeners employed "hand" manures. Wood ashes and lime were mainly used to keep ground pests in subjection and for correcting anything amiss in the land, especially the lime. Salt was used in a few gardens as a slug slayer, and manure for Brassicas. Rape dust, then much used by the farmers in the lower stretches of the land bordering on the Ouse for growing Potatoes and Wheat after them, was scarcely known in gardens any more than at the present time. Bones came to be used in various forms, but not until farmers had proved their value on grass land and gardeners finding that the turf from it gave splendid Grapes. Farmers used superphosphate, sulphates, and nitrates long before they were heard of in gardens. Of blood they knew more, for florists made rich composts of it, and grew flowers the like of which are not now seen.

Times changed, the farmers went downhill and the landlords followed; the dunghills became lower and smaller, while the manure tanks were oftener empty than full. All this is well known. Nothing flourished on land but the builder and general producer of all-round crops hugging the towns closely. The "artificial" was had recourse to as auxiliary of the "natural" manure. This, I hold, is the true principle of manuring. It is that of the market grower—"muck" is the foundation of success in growing anything. Foundation stuff will not grow crops profitably; but add manure to it, or organic matter, such as refuse fish, and then come satisfying results. Suppose we have nothing to do with "muck" in connection with foundation soil—inorganic substances, stones, sand, clay, stupid material—but use a few pounds of "artificial" manure, containing "as much available nutrient elements as a cartload of town manure"—what is the result? It comes out fine in pot experiments conducted with sterilised soil. What is the consequence in the bed, border, garden, field, farm, parish, county, country? It is a case of losing all along the line. —G. Abbey.

(To be continued.)

LILIUM AURATUM.

I think that this is probably the most disappointing of all Lilies; so difficult is it to grow that it is not in one garden in a hundred that it is established, and although tens of thousands of bulbs are imported every year, there is hardly anyone who can supply bulbs which have been growing three or four years in this country, and the case mentioned by Mr. Williamson on page 241 is a very exceptional one; in fact, so much is this difficulty recognised that gardeners mostly treat this Lily as an annual. I have grown it now for many years, and though I can grow most other Lilies, I can never succeed with this. It comes over in good and plump condition, and its growth for next year is already formed in the bulb; thus it flowers well the first year, but whether I grow it in pots or in the open the same result follows—the bulb either decays from the base or breaks up into a number of small bulbs, and the usefulness of the plant is gone. I have tried it in all kinds of soil and of situations, but have been equally unsuccessful in all; and now comes news which I fear will affect it still more.

Lily culture is a recognised industry in Japan, and, therefore, anything tending to its deterioration or extinction will be a calamity, and yet this we are threatened with. I had heard or seen nothing about it until I took up a recent issue of the "Standard," when I found it was honoured with a leading article. As a general rule the excursions of the daily Press into horticulture are more amusing than instructive, but when I saw in the article named that the "Kew Bulletin" was referred to as an authority for its statements, I felt that they were worthy of consideration and notice. The attention of the authorities was drawn to it by a London firm who had already lost heavily, for out of a consignment of 40,000 bulbs only one-tenth was unspoiled. Lilium speciosum, another Japanese Lily, fared still worse, for out of a consignment of 73,000 bulbs only 250 were fit for sale when they reached England. The disease then, or rather the fungus, Rhizopus necans, is of Japanese origin, and shows itself at the base of the bulb, spreading gradually upwards, that part becoming soft and discoloured, till the whole is affected, and at last is a soft pulp. Of course we do not know what the character of the culture is in Japan, but probably some of those like Mr. James H. Veitch, who have travelled there, may be able to tell us. We are all aware how injurious it is to most plants to grow them on the same piece of ground for successive years, and it may be that the Japanese have committed this mistake.

The fungus seems to have been unknown two years ago, and most probably the soil where the bulbs are grown is full of it. We all know how difficult it is to deal with the Potato disease, another form of fungus, and we might almost therefore despair of checking this, but the authorities at Kew have taken the matter in hand. They have subjected some bulbs sent to them by the London firm already alluded to to various experiments; they have found on cutting one of the diseased bulbs that it will in twenty-four hours be covered over the entire surface with a snow-white growth, which in three days is studded with numerous clusters of fruit, resembling to the naked eye miniature pins with black heads.

The object would be to destroy the vitality of the fungus, and it has been found that a solution of 1 per cent. of corrosive sublimate or of salicylic acid is fatal to the pest. But will the Japanese do this? They are generally tolerably "cute," and are not slow in taking any really good hints given to them, but we fear there will be a difficulty in getting the remedy applied. Is the ground where they are grown to be watered with this solution, or are the bulbs to be dipped into it and dried before being packed for exportation? It appears on the face of it as if the only efficient remedy would be for those who grow them in Japan to change their ground altogether, and I suppose most gardeners will be very chary of planting newly imported bulbs in their gardens. The fungus appears to take readily to other things, and especially to the Daffodil, which makes it the more dangerous.

Is it possible that the losses experienced by growers of this Lily have been due to some milder form of this fungus which does not seem to have appeared in its most virulent form until about two years ago? Other forms of auratum have been introduced, such as rubro-vittatum with its red band, and Virginale, pure white, and they partake of the same tendency as the typical form. Platyphyllum, which comes, I believe, from a different locality, was stated to be more robust than the older form, but I am not at all sure that this is the case. My bulbs of it this year, whether in pots or the open ground, have not done well, but then the season has been an exceptional one for some Lilies; but I shall be glad if this very fine flower, with its broad petals and good form, should prove more robust than the type.

There is another point on which Lilium auratum has been disappointing. Seeing how very prominent the reproductive organs are, and therefore how easily hybridised, it was thought that it would afford a good opportunity for passing into some of the other forms of Lilies; but with one exception no hybrids appear to have been raised, and this evidently partook of the defect which I have noticed in auratum, for it has never been distributed, and has, I believe, passed out of existence. This is much to be deplored, for it was a bold and striking flower, and would have been a great ornament to our gardens; indeed the hybridist does not seem to have done much to this tribe. Testaceum, or, as it used to be called, Isabellinum, is supposed to be a garden hybrid between Lilium candidum and L. chalcedonicum, and for its beautiful colour and complete hardiness has long been a favourite in our gardens. Of late years Mr. Powell of Southborough has raised a remarkable hybrid between Hansoni and dalmaticum. Never, perhaps, has the evidence of a true cross been more manifest than in this remarkable flower. Sometimes the effects of the cross fertilising are shown in the foliage, but very little of it is seen in the bloom; not so here, where the flower partakes equally of both parents.

There may be other hybrids, but I cannot call them to mind. The fine variety of speciosum called Melpomene is not a hybrid, but evidently a fine seedling variety. Just as we see in the imported bulbs of Lilium auratum, there is a great variation in the form and colour of the flower, and also in their time of blooming, some of them bearing very inferior flowers to others; it is also liable to what is called fasciation, that is, two or three stems joined together and quite flat. I have had specimens of this freak of Nature where upwards of thirty blooms have been crowded together; these are small, and the whole thing was valueless, except as a curiosity, and sure to die after the blooming season was over.—D., *Deal.*

CEPHALOTUS FOLLICULARIS.

It is not very often that this charming little Pitcher plant (fig. 36) is exhibited at our flower shows, and those staged by Mr. H. J. Chapman, gardener to R. I. Measures, Esq., Cambridge Lodge, Camberwell, attracted a considerable amount of attention at the last meeting in the Drill Hall. The plants were splendidly grown, beautifully pitchered, and a very great credit to their grower. One may go into establishment after establishment and never see a single specimen, large or small, and this perhaps makes them the more interesting. The following particulars will doubtless be useful to many readers of the *Journal of Horticulture*.

The plant is remarkable in several ways, for it is the only species of the genus, and is considered sufficiently distinct to constitute a natural order (allied to the Polygonums), and we thus have the peculiarity of a family composed of one individual. In the leaves, too, we find another singular feature—some are flat and elliptical in form, while others are converted into extremely neat and pretty little pitchers or ascidia, somewhat resembling those of Nepenthes, only much smaller. They are dark green with a purplish shading, and pink veins, and are furnished with

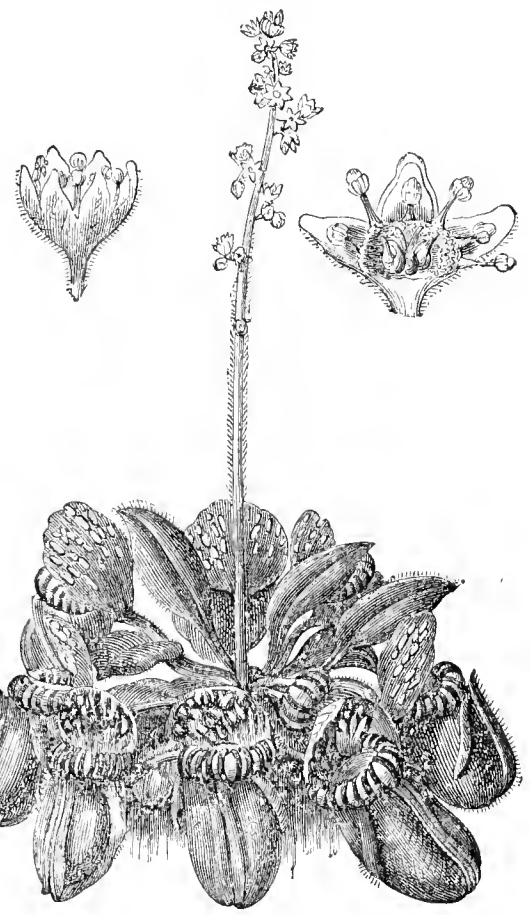

Fig. 36.—Cephalotus follicularis.

small lids, the mouth of the pitcher being bordered with a dark-coloured furrowed ring. This Cephalotus is an inhabitant of marshy land: it should therefore be provided with a soil composed of peat and live sphagnum moss, the pot being well drained and placed in a shallow pan containing water. If the plant is grown in a pan, that should be placed inside another larger one, the space being filled with fine Derbyshire spar and kept constantly moist. In either case a bell-glass should be placed over the plant. The best position and temperature is the cool end of the stove or Orchid house, where with careful attention in supplying the requisite moisture the plant will grow freely.

DECADENCE IN WALL TREE CULTURE.

From my own knowledge and observation I think it may safely be asserted that one great cause of the decadence in wall fruit culture lies in the fact, which may be summed up in a few words—want of time. This is deplored by your correspondents. Employers of gardeners require so much work doing in various departments, that wall trees often have to wait until favourable opportunities occur for attending to them. It is then frequently too late in the season for the operations in pruning and training, which ought to have been carried out sooner, to have the desired effect.

When trees fail to bear satisfactory crops a deficiency of interest is manifested in them, and the routine work they require to bring them into proper condition is allowed to be neglected. Wall trees are liable to fail in setting fruit, just as trees in the open are from untoward weather at a critical period, hence it is desirable to have the means at hand for protecting the blossoms, and thus insuring a crop. Trees in good health and vigour have a natural tendency to form an undue amount of wood, which would be checked by a reasonable crop of fruit. When the fruit is not there the trees expend their vigour in the development of wood; thus it is desirable that the attention in regulating this be given early and systematically, so that the checks may be steady but continuous.

The crowding of branches, large and small, is a too common source of failure in the culture of wall trees. If branches were at their formation disposed more thinly the management subsequently would be easier and the results considerably increased. Wall trees ought never to be planted in unsuitable positions. Trees are frequently to be seen struggling for existence where they have to compete for light and air with the branches of adjoining trees and shrubs. One or other has to suffer. Invariably it is the wall trees. It is not wise to tolerate inferior varieties of any fruits for cultivation against walls, but to ascertain which are the best and most prolific. Previous to planting the trees the best preparation possible should be accorded to the soil. Many failures may be traced to improperly prepared sites having a shallow, poor, and dry soil.

It is very tempting to the cultivator pushed for room to closely crop the fruit tree borders. This occasions constant digging, causing roots to descend deeply instead of remaining near the surface. Deep roots encourage strong growths, which, unfortunately, destroy the balance so essential to free and continued fruitfulness.

Wall trees are specially liable to insect invasions, though good and regular cultivation does much to prevent attacks. Cleanliness of the foliage must be maintained or the trees cannot long remain healthy. Insects prevent the leaves carrying out their important function of manufacturing material which shall be judiciously distributed in the growth of the tree whereby fruiting spurs or buds and wood growth are duly supplied. The most satisfactory wall trees are those which receive constant and unremitting attention. All operations connected with their culture and management must be carried out at the necessary periods, otherwise the whole tree may be thrown out of order to such an extent that double the time is essential for bringing it round again.

Some of the causes here indicated have brought wall tree culture into disrepute. There may be others, and among them the enormous attention given to Chrysanthemums. Growers of these can insure successful results only when all the details of culture are followed. No cultivator of the autumn flower would expect to achieve success if one or more of the essential operations were omitted. Fruit trees are more exacting than Chrysanthemums. It is only the best management in the most favourable positions that gives returns in a satisfactory manner.—E. D. S.

Yes, "Melton," the hounds are away. Let it be full cry. We may have some difficult country to traverse, and perhaps experience some nasty falls. It is the fortune of those who delight in the chase; but what matters so long as we are in at the death—the death of some popular fallacy?

My friend from the aristocratic hunting centre would fain know "how old I am!"—a pertinent question indeed, but one which has often been asked before. I seriously ask myself sometimes, when I notice how fast the grey hairs increase. They show that at least I am "no chicken," still I am not old enough to be an "old fogey." I rather rejoice in the fact, as also I do in the admission of the old hunter, "that fruit, generally speaking, is cultivated, so far as size and quality are concerned, as well as ever it was." That is surely the first consideration. The training of the trees is only a secondary one, and it speaks volumes for the zeal and knowledge of gardeners of the present day, that they have been able to do so well under difficulties such as the old generation knew nothing of.

Granted that gardeners as a body worked quite as hard half a century ago as they do now, but they certainly did not work more hours, indeed I question if at any previous time working overtime in gardens was so general as now, notwithstanding the fact that in all other trades and professions the hours of labour have been greatly shortened. True, gardeners would not mind even this, if by so doing they could keep their charges in the condition they would like, but as the matter stands at present, by reason of reduction of hands and increased demands in the way of decorations, the extra hours of labour are not spent in carrying out their "hobbies," but in doing work which does not benefit the garden proper, for the pleasant evening hours are largely taken up in dinner-table decorations, while true gardening must perforce be neglected.

Young men of the present day are as ready now as ever they were to work both early and late, and delight—as I have often done myself—in handling the Grape scissors at 4 A.M., and in doing the same kind of work in the evening till dark without a murmur; but when it is necessary for them to spend the same number of hours at extra unproductive work, while their growing crops are neglected, can they be expected to take such a delight in it? The truth is that when judged by present days, the "old gardeners" had a good time of it with their orderly time-for-everybody sort of life. Could they be here to-day in the rush of a modern gardener's life, it would—as "Old

Provincial" tritely puts it—be enough to "make their hair stand on end."

So "Melton" would have us believe that a tree trained in the perfect style of the old masters cost a good deal less than one managed on less methodical, though not less productive lines. I can quite understand anyone stating such nonsense, simply for the sake of argument or getting to know "how old" somebody is; but the only conclusion a practical man can arrive at in regard to such an assertion is that the writer knows little or nothing about training fruit trees. I have had charge of splendidly trained trees, not for one season only, but for many years; in fact, some of them were once written of in eulogistic terms by the guiding spirit of this journal. I always liked the work, and took a pride in it, but at the same time formed a strong conviction that in the majority of gardens the great amount of labour involved in the work might have been employed to better advantage in other directions, and that without lessening, but rather increasing, the supply of fruit.

To show the shrewd style of "Melton's" method of criticism, let me quote a sentence. He says, "In a certain ducal garden as much money was made from splendidly trained trees as "H. D." will ever obtain from an equal area of surface which trees are made to cover." It should have been much more, my friend, for, thanks to improved methods of culture, a given quantity of fine fruit will not command more than half the price it did the few years ago when I was in "button clothes!" This is, to a great extent, brought about by "rushing" the trees into bearing a year or two earlier than formerly. "Melton," in his abundance of years, seems to have a supreme contempt for time; to wait a few years more or less for crops is to him as nothing. But he attempts to go one better by asserting that fruit from young trees have more core and kernel than flesh. Such an assertion I defy anyone to prove, if the trees are fed in proportion to their crop. "Do not be vain," says my sporting critic, in a way that implies that, though vanity may be pardonable in so old a hand as "Melton," it is not so in one so young as "H. D."

Beautifully trained trees do not always mean poor crops, I admit, but I know also that many trees long noted for their splendid training but seldom have a decent crop; what little fruit is produced is generally at the extremity of the branches. Well-trained trees are satisfactory enough for a few years, but there comes a time when, if they are to be kept in a fruitful state, a change in management must be followed. Let us take for an example a horizontally trained Pear which has already covered its allotted space. After a few years it is by no means an uncommon occurrence for one or more of the branches to die, if not throughout the entire length, at least a good portion of it. It is then often a most difficult matter to get a good shoot to start at the right place to preserve the perfect form of the tree. Two or three years are perhaps wasted in the endeavour, and during all that time so much space is paying no toll. Now if, instead of waiting for the appearance of that rightly placed shoot, we train in side shoots from the nearest branches, the blank space is quickly covered with wood which will produce superior fruit, and the whole tree be greatly benefited by the freer style of training adopted. It is not "huddling and shuffling," mind you, but a style in which the side branches are given due space and disposed so as to cover it evenly. Thousands of handsome and well nigh barren trees which are supposed to adorn (?) the garden walls of this country would bear ten times the amount of fruit they do if every alternate main branch were cut away, and side shoots trained in to cover the space. Many of the foremost gardeners of present times have been shrewd enough to adopt the practice; they are not young men either, but have the common sense to adapt themselves to the spirit of the age.

"Melton" seems to fancy that a tree not trained in the old straight-as-a-gun-barrel fashion must be an ill-trained one; but this is a stupid doctrine, which has given the foreigner a fine chance to line his pockets by supplying us with fruit we ought to have produced ourselves. The real art of fruit-growing and of tree-training is to cover the wall as quickly as possible with healthy, evenly balanced branches which bear fruit from base to summit. I know plenty of labourers who can train trees beautifully, but if left to themselves precious little fruit would be grown, and—"whisper it softly"—I know others who have a perfect right to pose as gardeners, if a sound training has anything to do with the making of one, who do not cut a much better figure at fruit-growing than the intelligent labourer.

It is no new thing for the old in any calling to lament the decadence of the "modern men." Old actors have for generations declared that the "drama" is "going to the dogs," yet it still flourishes, and produces "stars" of the first magnitude. "Melton" is, I think, a bit of an actor as well as hunter, and the way he shows it, by breaking loose for a dash after the hounds, speaks well for his sense of dramatic effect. A grand old gardener in a sort of stage frenzy is a sight to remember—it awes some, amuses others, and instructs all. I fancy I can see the old gardener-hunter now, like a lion, chafing and lashing in his den. I'm off, to prepare for the roar of his music.—H. D.

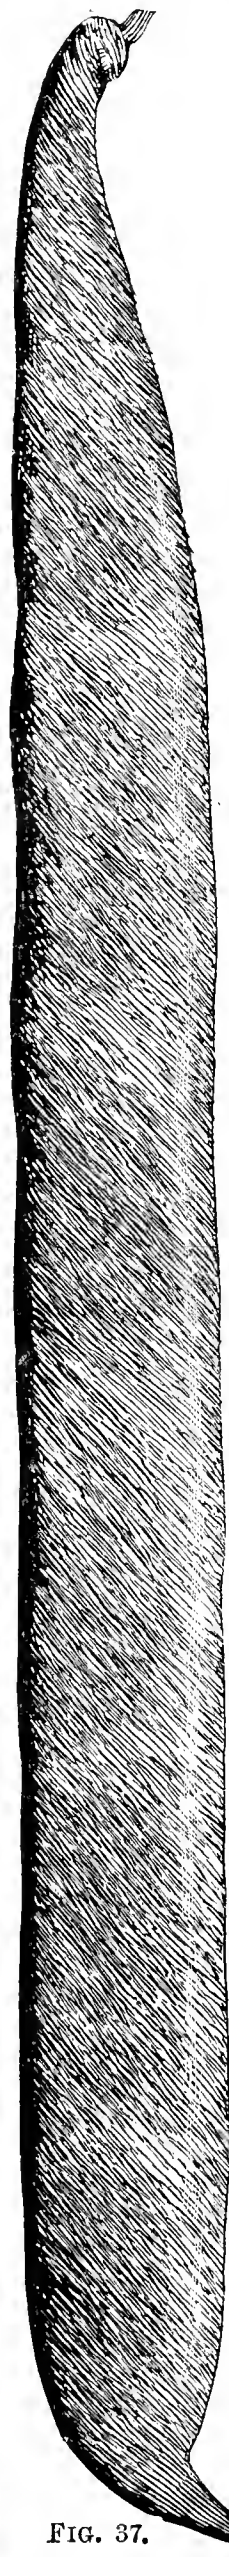

FIG. 37.

BEAN SUTTONS' PRIZEWINNER.

I SEND you a sample pod of this very fine Runner Bean, gathered by me in Forde Abbey Gardens, Chard, Somerset, recently, where Mr. J. Crook has some tall — indeed, grand rows, cropping profusely. It may be interesting to publish a tracing of it, as measurements in figures are not always regarded as exact. The outline will tell its own tale. We thus see in this straight handsome green, and yet very tender sample, how wonderfully Runner Beans have improved. —A. D.

[We were compelled to reduce the pod, which measured from the base of the stalk to the point of the curved tip exactly 12 inches.]

CAREX JAPONICA VARIEGATA.

BRITISH gardens now contain hosts of plants and Grasses which are grown for the elegance of their foliage, but few of them are more useful than this pretty Carex, which is peculiarly adapted for decorative work of many descriptions. Its perfect stage of development is reached when the sturdy pendulous flower spikes, borne on long footstalks, rise well above the grass-like foliage. Well-grown specimens in this stage are ideal ones for arranging in vases occupying prominent positions. A few of them disposed at well-chosen points in a boudoir produce a light graceful effect not easily surpassed. Smaller plants are of great value for dinner-table decoration, or for arranging in bowls, baskets, or larger groups of plants. Florists use the leaves largely in a cut state when dressing vases, or making wreaths and hand bouquets, as they may be included among the few good things which give to cut-flower arrangements the greatest possible amount of lightness in appearance.

The culture of this Carex is of the simplest description, but as is the case with all plants, whether easily grown or otherwise, a little extra attention is well repaid. During the summer months the plants thrive admirably in cool pits or frames which are closed early in the afternoon, with plenty of moisture to secure a genial temperature. During the autumn and winter I grow them in a stove temperature, in order to accelerate progress as much as possible, for no matter how large a stock of plants one has, the demand seems to keep pace with the supply. The present is a capital time to take in earnest the work of increasing the stock. Plants that are beginning to look shabby should be divided into small pieces having three or four stems. These, if placed in thumb pots—using a light sandy compost—will, if kept in a warm moist temperature, be ready for a shift in a couple of months. A good compost to use at this and subsequent pottings is one consisting of loam two parts, leaf soil, and one of well decayed manure, with a liberal amount of sharp sand added.

As soon as the roots are moving freely into the fresh soil abundance of water should be given, for it is surprising how rapidly growth progresses when the plants receive exactly the treatment they require in this respect. Let them get too dry at the roots, the points of the leaves quickly become brown, and in time "rusty" along their entire length. Whenever the weather is bright, either in summer or winter, I syringe the plants thoroughly once daily, and their appearance clearly indicates that they like the treatment.

Four and 5-inch pots are the sizes in which I find them the most useful, as they seldom grow more than 2 feet in height; but I intend to try some strong clumps in 7-inch pots, as such spread considerably, and will, I think, be

effective in large vases. Whenever the plants become shabby through constant use, after removing the disfigured leaves, they are placed in a warm pit for a few weeks till signs of young growths are visible. The whole stock is then dealt with, some of the plants being repotted, others divided and placed in smaller pots, then by keeping them in a warm moist pit they quickly grow into a useful size. If this course is persistently followed a good stock of serviceable plants is always at command.

When employing them for dinner table decoration, I turn the plants out of their pots, cut away the lower parts of the ball and bind fresh moss around the roots. I have often used the same plants at intervals for a period extending over three weeks. With regular attention in watering they seem to thrive as well in moss as when left in the pots, indeed the roots have a great liking for moss and interlace themselves among it. Noticing this some time ago I have since turned the knowledge to practical account in the following way: When the mossed plants have done duty for a time I press them into pots just as they are, and return them to their old quarters, where they grow quite as well as others repotted at the same time.—H. D.

CISSUS DISCOLOR.

Cissus discolor has long been esteemed for its attractively variegated foliage, and it may frequently be seen adorning the wall of a warm house or covering a trellis in a pot. Its culture is of the easiest, and it is so little fastidious as to soil that it will grow freely in any ordinary mixture and with no special attention. Those persons who have the unenviable peculiarity of spoiling every plant that comes into their possession, carrying the principle of how not to do it to such an extent as to make short work even of plants that no ordinary neglect nor mismanagement suffices to kill, have here a fitting subject on which to exhibit their maladroitness, as it would be a difficult matter to prevent it growing quite as well as, if not a great deal better than, the majority of stove plants.

The foliage of Cissus discolor is so beautiful that it may be employed most effectively for a great variety of decorative purposes, and this is a strong point in favour of the plant. Gardeners who grow it for the purpose indicated very frequently adopt the plan of encouraging a few plants to grow through the winter, while the others are resting and ripening, and when the latter are in growth subject the winter plants to a corresponding period of repose. There is no better plan for them to adopt, but the system opens out certain details of management that less experienced fellow workers might view with alarm, and it will be well to state at once that there is no necessity for them to risk venturing out of their depth with this very accommodating plant. It is much more easy to grow it well than to grow it badly, as I will show. The way to propagate the Cissus is by cuttings, and there is hardly a plant in the calendar, as I have proved over and over again, that may be more easily increased by this means. It will root more readily than a Chrysanthemum, and it may be inserted in much the same way. Prepare cuttings of the young shoots with three or four joints and insert them firmly in small pots just as you would a Chrysanthemum, using clean pots thoroughly drained, and filling them up with a very sandy mixture. In a warm house, and especially if kept close, it is astonishing how soon nice little plants will be had in this simple manner, and if the heat were not too dry I have no doubt they would root nearly as readily in a warm cupboard, although I have not tried them. These little plants can be repotted when they have rooted freely, and will then make rapid progress.

Three things our plant enjoys—plain substantial food in the way of soil, plenty of water (consequently the mould must be very porous and free), and a warm, genial atmosphere, such as would be comfortable for the grower as well as the plants. As to the first, do not wait expectantly for me to describe some special mixture. Perhaps a lesson will be learned by noting what the nurseryman had potted them in, but anyway, a free, fertile compost that will suit Fuchsias, "Geraniums," and Chrysanthemums, and which the local florist, were he consulted on the subject, would call "good potting stuff," will suit the Cissus admirably. If I could suggest any improvement at all it would be to add a little more sand. Plenty of crocks must be used over the large piece that covers the hole in the bottom of the pot, otherwise the care taken to provide a porous soil would be so much labour lost. When potted the plants must be examined frequently, and the soil never allowed to become dust dry, but copious supplies of water given before the mould is in such a condition as to fall through the fingers when rubbed. Syringing should also be practised several times a week when the plants are in free growth. Give them plain food and they will not languish for dainties; give them plenty of water and they will need no wine.

I have spoken of trellises. Vigorous plants in large pots may be trained to these if desired, and very handsome they look with their marbled foliage clothing them well; but there is another way of growing them, and that is to plant them out in the border to cover a wall, letting both root and top growth have free play. A well-covered wall gives a fine effect. Strong plants should be put in and adequate provision made for drainage. Whether grown in pots or planted out the plants, like Fuchsias, will want a winter rest, and like them they may be pruned, shaken out, and repotted when breaking into fresh growth in spring.

There are one or two other points in the cultivation of Cissus discolor which I had intended to refer to, but my allotted space is already more than full. One of them was loss of variegation in the leaves, but if I merely state that rich soil and unchecked sun heat both tend to this, the means of avoiding it will be obvious.—P.

DECORATIVE WORK.

(*Continued from page* 234.)

On the larger scale of our subject the primary features of church decoration in its different phases may claim attention. Harvest festivals now at hand generally necessitate the inclusion of a heterogeneous amount of material, comprising individual offerings, which under the circumstances must perforce be used. This, however, if playing a prominent part, is, so far as the principal points are concerned, but accessory to them. To enumerate the varieties of material so profusely furnished at this particular season is scarcely necessary; one needs only to mention the wild Hop, the Traveller's Joy Clematis, and the Virginian Creeper which, possibly, afford the most elegant drapery one could have for the purpose. Other things, also, of a similar nature suggest their suitability for being thus employed. The manner of employing them is, too, so generally obvious as to call for but little remark.

Stately Palms lend by their presence at all seasons a dignity peculiarly their own, and those who have seen twin specimens of Seaforthia elegans towering high over the chancel rails will agree as to the excellence of the effect obtained. One such pair was used repeatedly in a particular church, and a leaf of each plant caught together at the points by an invisible tie formed a perfect arch, whilst the tubs were concealed by an enveloping group of Ferns and Panicum plicatum. Difficulties often arise from the prohibition of nails or from its being impossible to use them amongst stonework. A little ingenuity will, however, find means to the end of securing wreaths or other greenery to the outlines where tying on is not available, but no doubt should remain as to the security of the method of fastening.

Apropos of the above, one occasion is recalled when a very uncomfortable half hour was spent whilst our worthy pastor preached his Christmas sermon, due to some little difference of opinion arising on the previous day over the securing of a substantial Holly wreath which outlined the top and base of the pulpit. This being a fine example of carved Caen stone, my plan of securing the wreaths did not meet with the approval of our good minister, who, being of a mechanical turn of mind, devised a plan whereby the whole decorative fabric depended upon one nail fixed in the flooring to which the principal strings were fastened. This was sufficient, provided the reverend foot did not dislodge it, and though declining all responsibility for the makeshift, the promise of "I'll be sure to keep clear of it," was not received without misgiving, unfortunately justified on the morrow, when warming to his discourse, the good man entangled his foot in the strings, and, to our mutual dismay, the wreaths collapsed. However, out of evil came good, and on the next occasion some light U-shaped steel springs were worked into the ends of the wreaths which clasped the stone edges and prevented any further catastrophe of the kind.

Such things are, however, rather a matter of detail than of that broader conception fitting a framework of tastefully arranged foliage, which, whilst bold in design on the one hand, is not, on the other, heavy enough to hide those architectural features it is only intended to adorn. Examples of this kind of work may even here miss the happy medium through an over-refinement of detail. For instance, a delicate construction composed of Wheat ears or Barley arranged as wreaths, and often used to ornament the front of a gallery of some considerable length, savours too much of those straw plaits our coachmen use for their stables, and are only produced with the same infinite care and labour. The end attained does not appear to justify the elaborate means employed when, at half the expense of time, more satisfaction is derived from what is bold and striking, if more roughly manufactured. This may not mean much in a way, unless from a gardener's point of view, which we are now considering; then, to a man troubled with many things it means a good deal.

Decorations of this kind may often have to remain for some considerable time, compared with the fleeting subjects of cut flowers and foliage, of which they largely consist. The contrast between the pristine freshness of the first day and that of a week or more is often strongly in evidence, but much of this is preventible by a little careful

selection of the most enduring material, as well as its treatment. Respecting cut bloom, with its complementary supply of foliage, apart from the groundwork composed of hardier things, ordinary pickle bottles or preserve jars filled with water are very useful; Dahlias, Gladiolus, Tritomas, and other showy things being retained to the limits of endurance. Groups of one kind only of such flowers give an admirable effect when the jars are effectually hidden in a cushion of fresh green moss, from which the flowers spring in a natural manner.

In this, and in other phases of bold decoration, a liberal introduction of the common Water Flag, Iris pseudo-acorus, will often more than compensate for shortcomings in other things. This I have frequently and largely used in various ways with the most satisfactory results. Carefully cut at the base, and piled in flat bundles to carry without breaking, it is admirable when naturally disposed in wet sand or vessels of water for use in various positions which suggest themselves, and notably as a background in windows to brighter things placed in front. In water or a moist medium the lasting properties of the Water Flag are unequalled. Those who have to cater specially for harvest festivals are happy in having a few pot Vines which grow as long in cane as possible, and, bearing some fair bunches with the bloom undisturbed, are the *beau ideal* of all that is graceful and appropriate at this season.

As an auxiliary to the usual evergreen decoration at Christmastide, the question of pot plants of tender type is often one of anxiety, if not of annoyance to the provider. Well berried Aucubas grown in small tubs are good substitutes for more delicate plants, but lately I saw a whole collection of Yews, Bay Laurels, common Laurels, and Aucubas, with a few of the more elegant Coniferæ solely grown, with some special treatment in the way of training and pruning, for this purpose, and the head gardener, who was also the principal decorator, said what a relief it was to him to have this contingent to draw upon. Amongst these particular noticeable were English Yews, one pair of which were trained and clipped into a perfect semblance of the Irish cross, some 10 feet high; another pair being obelisk-shaped, and equally perfect in their way. This matter is, however, one of taste, and one which it is neither desirable nor necessary to criticise here.

Permanent objects, such as above mentioned, are much handier, though the specimens be but small, if grown in tubs instead of pots, and with the tubs covered by virgin cork will never be unsightly when time or space do not admit of further dressing. Board borderings of 6 or 9 inches in depth, covered on the face with the cork, are well adapted as an edging for window-sills, to which they may be securely fixed with a small wedge. These also form an appropriate margin to groups placed on the floor, and once made and kept for the purpose facilitate matters considerably, requiring but some fresh green moss packed in the interstices of the cork upon each occasion of using. A few pots of Panicum variegatum gracefully hanging over this cork-covered margin have an extremely good effect.—DECORA.

(To be continued.)

WALKLEY FLORAL SOCIETY.

THE bi-monthly meeting of this Society was held on Friday, the 10th inst. Mr. J. Haigh, Vice-President, occupied the chair. A large number of excellent plants and flowers were staged. This Society, unlike many of its kind, never competes for money prizes. On each meeting night through the year there are special exhibits, but each member is at liberty to bring anything in the way of garden produce that he has suitable for exhibition. In lieu of money, marks are awarded to each exhibitor, six being the maximum number. At the end of the year, on the occasion of the Society's annual dinner, special prizes, given by members and friends, are awarded to those who have obtained the highest number of marks. The judges at each meeting are professional gardeners, whose duties are previously assigned to them, and printed on the programme.

After the usual routine business had been disposed of a paper on the Auricula by Mr. "Ben" Simonite was read. In his usual plain and clear style he dealt with the show varieties (his special *protegés*) in a most excellent manner, and fully explained his *modus operandi* of cultivating this old-fashioned flower. Although his gardens are situated in one of the most smoky districts of Sheffield, his success as an exhibitor testifies to his skill in Auricula culture. It is often said that no man is a prophet in his own county. "Ben," however, is an exception to this rule. He is an "oracle" in Sheffield in all things floricultural.

His reception at the meeting was a good one, and a hearty vote of thanks was given him for his valuable information, and for the ready manner in which he answered the numerous questions asked after the reading of the essay. With reference to the fertilising of the flowers and the gathering of the ripened seed, an amusing instance of the difference of opinion, or rather lack of knowledge, was mentioned. It occurred some years ago, when a firm in the Emerald Isle wrote to Mr. Simonite asking the price "per pound" of his best Auricula seed. Now when we consider that he has been cultivating the Auricula for about forty years, and has probably not in all that long experience saved more than 2 ozs. of good seed, it is, to say the least, very amusing.—J. H. S.

OUTDOOR PEACHES.

I HEREWITH send you a sample of our outdoor Peaches, of which we have a great quantity. I might say that these are by no means the best, as with cold storms and low temperature we have had this last fortnight, they are not so good as we had previously. We picked the first fruit on the 12th of July, and we had Peaches last year until 12th of October.—WM. CAMM, *Battle, Sussex.*

WHEN so much interesting discussion is going on in the columns of the Journal respecting the "decadence" of gardening, and of open air Peach culture in particular, I thought the time opportune to send you specimens, one taken from a south wall, the other from a west aspect. Many scores of such fruit adorn our trees at this moment. I will write a short note for the columns of the Journal in due course.—WM. WEST CHAPMAN, *Bedfordshire.*

[The fruits sent by our correspondents are excellent, as are specimens forwarded by Mr. G. R. Allis from trees against unprotected walls at Old Warden, Beds. Outdoor Peaches are grown in some gardens as well as ever they were, but not in half so many as was the case a generation ago. In thousands of gardens now the Peach supply is practically grown under glass.]

LESSONS OF THE SEASON—FLOWER BEDS.

IT is always interesting to note those plants in the flower garden which have done well during the past summer, also those which have answered moderately so, and those which have failed. The closing summer has been a fickle one. During May and June, while bedding out was going on the weather was most trying. The heat was intense, and for several weeks the plants made little progress. Fortunately, rain came, and the beds were soon filled and gay. Then came one of the most disastrous hailstorms ever experienced in my district, which simply stripped such things as Cannas, Zeas, and Begonias into shreds. For the moment we looked on with dismay, and thought that the case was a hopeless one. However, I knew this would not answer, as the garden would be expected to look gay and at its best by a certain date. I therefore set to work filling up gaps here with surplus plants, plunging more there, such as Lilies, Cannas, Fuchsias, or whatever came to hand which was bright, and this has taught me some valuable lessons, some of which I will relate.

Those plants which have stood the ordeal best are as follows:—

Fuchsias, of course, lost some of their flowers for the time being, but this was the only harm they received. Two beds of standard Fuchsias with clear stems 3 feet high, and heads as much through, in a carpet of Antirrhinum lutea, were much admired, and stood the storm well. The Fuchsia was the variety called "Charming," which is one of the best for bedding. The Antirrhinum is of the brightest yellow, and very compact in growth.

Another very attractive bed was planted with Sunray Fuchsia in a carpet of Blue Bell Viola, edged with Antennaria tomentosa. This also withstood the hailstorm well.

Two other large beds were filled with Lilium lancifolium roseum in a ground of Marigold Legion of Honour, edged with Lobelia compacta. This was much admired. Another large bed was planted with Lilium auratum, in a ground of Begonia Duchess of Edinburgh, edged with Dactylis glomerata variegata and Iresine Lindeni. The Liliums have done well, as have also the Begonias.

Other beds were filled with shapely plants of Fuchsia Charming in a carpet of Harrison's Musk with a band of dark blue Lobelia and margin of Antennaria. The Fuchsias are at present, and have been for some time past, one mass of flower.

Mixed Begonias are splendid. The flowers are large, bright, and plentiful. These, in a carpet of Harrison's Musk, are amongst the best of summer bedding plants. It is astonishing how rapidly these plants recovered from the battering they received from the hailstorm.

Reverting to the miscellaneous plants I was compelled to try in the garden, there are a few which have exceeded my expectations for their durability. Impatiens Sultani was placed out to fill up vacant places where the great storm broke down such plants as Ricinus, and at the present time is one mass of flower, very much better than is generally seen in warm houses.

Coleuses, such as the fine broad-leaved and highly coloured kinds, which are only as a rule grown under glass, were placed out, and these have done remarkably well, continuing to grow and colour superbly.

Trachelium cœruleum was also planted, and kept gay for a long time, and in a ground of Gazania splendens produced a fine display. I shall, all being well, plant a bed of this next year, and I have no doubt it will answer well.

Amongst plants which have not recovered so rapidly are Cannas; where these were in exposed places they still look shabby, and "Geraniums" were a long time before they recovered and became attractive.

The semperflorens type of Begonias are very useful bedding plants. I have planted those sent out two years since by Messrs. Sutton & Sons, and am well pleased with them. They are so easily grown from seed sown early in the year that they save an enormous amount of trouble in raising cuttings.—T. A., *Cirencester.*

[We are obliged to our correspondent, to whom the storm seems to have been something like a blessing in disguise. "Lessons of the Season" from other districts on flower gardening and other subjects, could scarcely fail in being interesting, suggestive, and useful.]

Notes & Gleanings

Events of the Week.—Metropolitan horticulturists at last have almost a week of rest before them, for the exception of the meeting of the Royal Horticultural Society on Tuesday, September 21st, we know of no show in the neighbourhood of London. No doubt there are one or two provincial fixtures, but of these we have had no notice.

—— Weather in London.—On the whole we have had a much finer week, for which the late holiday makers may be thankful. On Thursday morning some rain fell, and the remainder of the day was dull and heavy; but Friday was bright and quite warm. Saturday was a beautiful day, the sun shining gloriously, Sunday also being fine. Monday was quite warm at times, becoming cooler towards night. Tuesday opened dull. Wednesday was alternately bright and cloudy.

—— Are Roman Hyacinths Poisonous?—While recently potting some Roman Hyacinths I felt an unpleasant itching sensation about the arms and neck. I naturally rubbed the affected parts, and the itching became almost unbearable until I washed my face and arms, when it stopped almost immediately. I mentioned the incident to a gardener friend, who said he was always troubled in a like manner when potting Roman Hyacinths. It would be interesting to know if any of your readers have had similar experience, or can explain the reason, and name a preventive or remedy.—J. C., *Lancashire*.

—— Florilegium Haarlemense.—We have referred to this admirable publication in a previous issue, and have now received part 4, which was published so long ago as December, 1896. Unfortunately part 3 has not come to hand, so that our sequence of the plates will not be quite correct. The one before us contains Hyacinth Ida, beautifully reproduced; Tulips La Precieuse, Rose Gris de lin, Rosa Mundi, and Rose Luisante, all on one plate; and a third of Gladiolus Colvilli, with the white varieties. The publisher is Mr. de Erven Loosjes, Haarlem, from whom a free specimen copy may be had.

—— Scottish Horticultural Association.—At the monthly meeting held at 5, St. Andrew Square, Edinburgh, on Tuesday, 7th September, Mr. D. T. Fish delivered a lecture on "Fruit and Flowers in our Home and in our Life," to a large and attentive audience. The lecture falling on the eve of the Royal Caledonian Fruit and Flower Show brought to the meeting some English visitors. The lecturer referred to the beauty of spring with its benefits and effects on the human life, following with the fulness of summer and autumn, the season of plenty. The scientific element was admirably touched upon, and many practical hints were given. The Chairman, in proposing a vote of thanks, alluded to the labour, study, and loving energy embodied in the lecturer's references. Hearty thanks being accorded, exhibits commented on, and next meeting's subject announced, the gathering ended.—J. H. Dick.

—— Some Good Potatoes.—In the finely cultivated soil of Hackwood Park, where rotten leafage plays so important a part in the fertilisation of the ground, Potatoes always do well and give fine crops. When there a few days since roots of several varieties were kindly lifted for me to see. Amongst them were Sutton's Satisfaction, always a great crop of fine tubers, and their new midseason white kidney Reliance. This gives a remarkable root produce, the tubers being of true kidney shape, handsome, and even. It is a good break into the kidney section that is much needed. Others were a variety named Progress, which gives enormous tops and huge stems, but this season, whatever its general merits, has no tubers, being all root thongs. It is not one of the Reading varieties. A capital late variety is the Saxon, tubers white, pebble shaped, and handsome. The tops, however, show unmistakeable likeness to those of Magnum Bonum, although it is a very diverse variety. One of the finest is the northern "Up to Date," a Potato that will soon be universally grown as a late garden and field variety. The crop at Hackwood is a very heavy one, and not a tuber lifted showed any disease. The tubers are not unduly large, not one was ungainly, but had a flattish long shape, something like that of the old Lapstone, and very even. I noticed in the first root lifted, a capital sample, enough for two families' dinner. No wonder with such marvellous croppers, as we see in this and other varieties, that, in spite of disease, Potatoes are always so cheap. Clearly our Potatoes are up to date.—Expert.

—— Gardening Appointments.—Mr. W. P. Bound, for some time past with Messrs. F. Sander & Co., St. Albans, has been appointed head gardener to Mrs. Leveson-Gower, Bill Hill, Wokingham, Berks, and enters upon his duties on October 2nd. Mr. J. H. Cumming, formerly at St. Helen's, Booterstown, has been appointed head gardener to Lady Stewart, of Grantully Castle, Ballinluig, N.B.

—— Allamanda Williamsi.—There has long been blooming a grand plant of this delightful Allamanda at Hackwood Park, growing now in a 14-inch pot. The plant when I saw it a few days since was, from the pot, 5 feet in height and 6 feet through, being literally a mass of flower. It would have been hard for any other flowering plant to have beaten it in a specimen competition. Would that we could see more of such examples of plant culture as this at the Drill Hall, and not so much of commonplace stuff. This plant is but four years old; if in such fine form next year it should be worthy of pictorial illustration.—A. D.

—— Hybernation of Insects.—At the annual meeting of the American Association of Economic Entomologists Dr. R. O. Howard of the Department of Agriculture, Washington, District of Columbia, speaking of the effect of temperature upon the hybernation of injurious insects, stated that in experiments with such insects in cold storage a consecutive cold temperature proved favourable to successful hybernation, while a low temperature, followed by a high one with a return to a low one, almost always resulted in death to the insect. The conclusion is that a steadily cold winter with a temperature even much below the average will usually be followed by an abundance of insects, and that after a winter characterised by alternate cold and warm spells fewer individuals will survive.

—— Sheffield Chrysanthemum Society.—A general meeting of the Society was held on the 8th inst. for the transaction of its general business. Afterwards a paper on "Grape Culture," by Mr. W. H. Winter, was read. According to the programme of the Society, a paper entitled "Plant Life" should have been given, but owing to sickness Mr. Winter was unable to attend, so he sent the one on Grapes, which was read by one of the members. The exhibits for this month were Cactus Dahlias, and a capital display was staged. The flowers were good in size, shape, and colour, the latter being attractive by their variety and brilliancy. The awards were as follows:—Messrs. J. Needham, G. Smith, and C. Scott secured first, second, and third prizes in the professional section; and Messrs. W. Willgoose, W. H. Hinchliffe, and H. Broomhead first, second, and third prizes in the amateur section. Mr. J. Haigh presided over the meeting.

—— Splicing Grapes at the Late Crystal Palace Show.—I am sure the public and exhibitors generally are deeply indebted to Mr. Hudson for detecting and exposing the fraud at the above Show, but as an exhibitor I do not think this is sufficient. I consider that the name and address of the offender should have been given in justice to others, for of all the mean tricks connected with exhibiting I contend this ranks among the very worst, and should be fully exposed. Surely the innocent exhibitor would not mind the publication of his name, he himself knowing nothing about the splicing. But the clever young assistant—for clever he must be to deceive his master as well as the Judges on the first day of the Show—should certainly be taught better, or what will he develop into later on?—Observer. [The exhibitor has now an opportunity for declaring himself. Some of the best and cleverest men in the world have been the victims of deception from time to time.]

—— The Hemel Hempstead Horticultural Society.—A newspaper report has been sent to us of the thirty-eighth annual show of this Society. It was, we believe, started in a very small way by Henry Balderson, Esq., a diligent member of the Fruit Committee of the Royal Horticultural Society. We should not like to count the classes now, for the prize list fills three long columns of a newspaper. There appears to have been great competition in the floral, fruit, and vegetable departments, and especially in the allotments and cottagers' section. Agriculture and apiculture are represented, and the domestic arts encouraged, Mr. Balderson giving prizes for needlework, cooked Potatoes, and home-made bread. Great good must have been effected by the agency of the Society, though it has raised the price of bread. Observing the custom of the prizegiver in purchasing the best loaves, ways and means have been found by the enterprising competitors of making him pay 2s. each for them. However, he seems to regard it as one of the good deeds of "Heavenly" Hempstead, and looks well on the fare thus provided.

—— Supplement to the Index Kewensis.—We are glad to learn from the "Kew Bulletin" that M. Th. Durand and Mr. B. Daydon Jackson have made arrangements for printing their ten years' supplement to the "Index Kewensis," which will bring the work down to the end of the year 1895. It is hoped it may be issued during the present year.

—— Sharpe's Waltham French Runner Bean.—This may be fairly described as the most remarkable Bean in the Chiswick trials this year—not by the size of the pods, but for their wonderful profusion. The seeds are small and white, and the committee of inspection gave the variety commendatory marks for cooking as a Haricot. The pods could be literally gathered in handfuls.

—— Potatoes at Chiswick.—About eighty varieties of Potatoes have been tried at Chiswick this year. The early varieties were examined some time ago, the later last week. From the thirty-six varieties lifted in the presence of a committee ten were selected because of their excellent yields of shapely tubers, free from disease, for cooking. For three of these three marks of merit were unanimously awarded—namely, *Lidstone's Cardinal*, white, round, fine crop, and excellent quality; *Major Curtois* (provisional), full crop of uniform, pebble shaped, tapering tubers of superior quality, very distinct; and Horsford's Seedling, from Vermont, U.S.A., very productive, pebble shaped tubers of good quality. Sutton's Windsor Castle, handsome tubers, was also cooked, and the certificate granted in 1893 unanimously confirmed. Thus there is no deterioration in this valuable Potato.

—— Plums at Hackwood Park.—When a few days since looking along the walls at this place I could but think how wide of the mark it was for anyone to write about the decadence of wall fruit culture. Certainly I have seen no evidence of it anywhere. At Hackwood Plums are not only very extensively grown on walls, giving in good seasons splendid crops, but the trees are admirably trained. Better they could hardly be, and not on any horizontal system so recently advocated by Mr. A. H. Pearson, but on the old fan-shaped method. September 9th is rather late to find many good Plums out southwards, but on an east wall, Archduke, a noble late purple Plum, was in splendid condition, carrying a good crop. This is one of Mr. Rivers' finest introductions, without doubt, amongst Plums, and should be universally grown. Then on a north wall are six fine fan trees of the much decried Victoria, and these had all carried a capital crop. Two of the trees had been cleared, the other four being netted up and stripped as used. Mr. Bowerman will have these good up to the end of the month. These six trees run from two parts length of the north wall to the end or corner, and there is just beyond the corner on the west wall yet a seventh tree, also a good one. It is, however, a curious fact that this tree, whilst blooming well always, yet hardly sets a fruit. It seems inconceivable that, treated exactly alike, the mere change of aspect, and a sheltered position, too, should yet make so much difference. It is, however, worthy of notice Mr. Pearson deprecated the planting of so common a Plum as the Victoria on warm aspects. Here we see how finely it does on a north one.—A.

—— Tomato Varieties.—Those who, like myself, occasionally, as it were, get behind the scenes, hear some funny things from gardeners who get to learn of each other's doings as though by a species of freemasonry. Now were I disposed to be malicious, which by-the-by I am not, I could name a dozen diversely named Tomatoes in commerce that are so much alike, should I be permitted to gather but one selected fruit of each stock, to mix the seed, and raise the plants, I would defy all creation to tell me wherein any difference could be found. A gardener once found in a stock of an American variety one plant that showed excellence over the rest. He saved the seed, grew plants, and found he had got a stock of an improved variety. He gave some seed to a gardener friend, and he grew stock. Presently under diverse names the variety went from both gardens into commerce. A third gardener got stock of it, and grew it; then that stock got into commerce under a third name. He gave some seed to a fourth gardener, who also grew it, and not waiting longer to farther select it, sold his stock under yet another name to a fourth firm, and in another part of the kingdom the same stock appeared under a fifth name; indeed it would not be at all difficult to find many more. Now when we see these stocks, all first-class, I admit, and so far as I see in regard to cropping and beauty, as well as solidity of fruit, absolutely unbeatable, can it be wondered that I view the introduction of so-called new varieties, not distinct, with grave doubt and suspicion? Anyone who may overhaul the Chiswick pot trials will see for themselves how marvellously like to others are so many of the so-called new ones sent there to be grown. Practically everybody now has everywhere first-class Tomatoes.—A. D.

—— The Black Locust.—This a common tree in West Virginia where it is found in groves of considerable extent, and is of great commercial value on land that has been allowed to revert to forest after having been used for agricultural purposes. In the late annual report of the West Virginia Experiment Station, Professor Corbett says that it is considered of greater value than any native wood for use as driving blocks in sinking points for driven wells. The timber closely approaches in value that of Red Cedar for posts, and this, together with its rapid reproduction, constitutes its greatest value, although it is much sought for by the manufacturers of hubs for carriage wheels and for other uses where great resistance to pressure is required. According to an American contemporary, the largest Black Locust in West Virginia stands near the entrance of an abandoned coal mine, not far from Morgantown. It is a remarkable tree, being fully 4 feet in trunk diameter, and at least 100 feet in height.

—— "He Could not Stop when he had Finished!"—What a suggestive sentence in the leading article of last week! "It is a very common fault." It is, indeed; and a most exasperating one. Who has not suffered under the speaker who has said all he has to say, and still goes droning on? It is the fault of most long sermons. "Half is," how often! "better than the whole." Indeed, there is a pregnant Greek proverb to this effect. Those who have to reprove often evidence this. The first few words would have a good effect, but they work themselves up, and then other people also, until at last warning is often given, and a most unnecessary parting takes place. *Ne quid nimis* is a valuable Latin rule. Don't overdo it! Was well—would be better—took physic and died. But the text I have taken applies most of all to oratory. The ten minute rule is excellent, and still better the five. Best of all that advice, the quintessence of common sense, to every budding orator—"Have something to say, say it, and sit down."—A. C.

—— Wolverhampton Gardeners' Club.—A lecture on "Orchids" was given to the members of the Wolverhampton Gardeners' Horticultural Club on the 7th inst. by Mr. H. A. Burberry. He dealt with his subject from the standpoint of gardeners having restricted glass accommodation, and dwelt chiefly on those kinds requiring little warmth so far as the hot-water apparatus is concerned. The culture of cool Orchids was fully and extensively referred to, dividing them into two classes—viz., the warmer and the cooler, the former differing from the latter only because more sun heat should be given during summer when they are growing, and fully describing the conditions which should prevail in each department. He enumerated a large number of the most popular and showy species which would grow and flourish under similar conditions. This at once made the frequently difficult and troublesome matters of culture and selections easy to understand. The cordial manner in which the vote of thanks was proclaimed by those present sufficed to show how greatly Mr. Burberry's remarks had been appreciated.

—— The Fruit-flavour Competitions.—Not being at the Drill Hall on the 7th, I looked for the Journal with exceeding interest on my return from the West of England to see your report of the Apple and Pear flavour competition on the above date, and was immensely pleased to find that a recommendation of mine to Mr. Mayne of Bicton Gardens, Devon, when there on the afternoon of the 6th, to send up a good sample of his Kerry Pippin, had so satisfactory a result. When looking over the fruit in company with Mr. J. Crook I at once said, "Why not send half a dozen up to the Drill Hall for the flavour competition on the next day?" My suggestion was at once acted upon, and the fruit packed and sent off by post. I think, so far as I remember, that was the first lot of this really delicious early dessert Apple that had come before the judges. Let Irish readers take notice that Irish Peach was placed first on the 24th of August, and now Kerry Pippin is placed first on September 6th. If any miserable Saxon should now contemptuously ask, "What good thing ever came out of Ireland?" the Celt can reply, "Yes; two of the best early dessert Apples in cultivation." A very beautiful early Apple, Miller's Seedling, shown recently at Reading by Mr. Turton of Maiden Erlegh and Mr. Fyfe of Lockinge, having lemon skin with pretty red stripes on it, has so far not yet found its way to the Drill Hall competitions. It is, however, too late this season. And here I cannot help drawing attention to the ignorance which prevails in the country amongst gardeners with respect to this flavour competition. I have done all I can to make it known, but hardly a gardener seems to be aware of it. Some leaflets of the competition seem to be needful, and widely distributed. At present the limited competition and practically the same exhibitors is making it rather ridiculous.—D.

—— London Allotments.—In the report for the current year the Small Holdings Committee of the London Council expresses regret that another year has passed without any amendment of the law being made enabling the Council to provide allotments in the county of London. The Council, says a contemporary, is still unable to let small plots of land direct to tenants, but is forced to proceed under the Small Holdings Act, 1892, under the provisions of which the Council lets land in plots of over one acre in extent to tenants who, by the terms of their agreements, cultivate a specified portion of their holdings and sublet the remainder to approved sub-tenants. The Council is desirous of acquiring legal power to let plots of less than one acre direct to persons who wish to take them. The Local Government Board has issued orders conferring the powers of a parish council in regard to hiring land for allotments upon the vestries of Charlton and Greenwich, but the Committee is of opinion that the power only to hire land scarcely meets the case, and they hold that local authorities should be authorised to purchase land for the purpose. During the past year the working of the Council's allotments at Millmeads and East Ham, and of the small holdings at Perry Rise, Plumstead, and West Norwood, has been in all respects satisfactory. Additional land at Plumstead, about 13 acres in extent, has been taken on a tenancy for seven years at a yearly rental of £33 9s. The Council has also taken a tenancy of about 11 acres of land in Shooter's Hill Road, Blackheath, at £25 a year. The Council's officers have endeavoured to find suitable land in other localities, "but," says the Committee, "experience proves that landowners are not often willing to grant leases on terms which the Council could be recommended to accept." The number of cultivators on the existing allotments and small holdings of the Council is 588.

—— Kei-Apple as a Hedge Plant.—This shrubby South African plant (Aberia Craffra, *Harv. & Sond.*), a member of the Annatto order (Bixineæ), is armed with long spines, and makes excellent hedges. It is evergreen and bears fruit like small yellowish Apples. When fresh they are acid and used as a pickle; when ripe they make a good jam. The "Waikato Times" of New Zealand recommends the Kei-Apple as a hedge plant in the following terms:—"One is always hearing complaints nowadays of the paucity of good plants suitable for hedge purposes. This harbours the Wheat rust or the leech, but dies out in patches, while another would be admirable were the cows not so fond of it. This being so, the thanks of the community are due to Mr. A. Tempest of Parnell for his enterprise in introducing and propagating the 'Kei-Apple.' It was Sir George Grey, I believe, who first mentioned the shrub, which grows wild upon the Karoo, or sandy plains of South Africa, and it certainly seems a perfect hedge plant. It is a sturdy, stocky, short-jointed grower, an evergreen, and with thorns which grow to 6 inches long and over, and a 'perfect terror to evil doers,' be they beasts or human beings. As an added advantage, the female plants (they are of both sexes) fruit heavily, bearing in great quantity yellow Plum-shaped fruit, the size of a Green Gage, which are both pleasant eating, and make an exquisite jam. Orchardists would do well to bear this shrub in mind when planting." To this the following note is added in the "Agricultural Journal" of the Cape of Good Hope:—"It will be noticed that a wrong part of the country is stated to be the native habitat of this plant, but all the good qualities as a hedge plant are perfectly true. In some old books of travels in South Africa it is stated that on the eastern coast there were 'wild Apricots;' were these Kei-Apples? Few people like to eat the fruit raw, but the jam is first-rate. A proportion of Kei-Apple with Tomato would make a good jam."—("Kew Bulletin.")

TOMATOES FOR WINTER AND SPRING.

As Tomatoes have rapidly gained favour with nearly all classes of society my subject must be a popular one. It is generally admitted the taste for this esculent must be acquired, consequently the start should be made with perfectly ripened fruit; and later on, if this cannot be had, fruit of inferior quality, such, for instance, as that imported, will be relished. The recent advance in house culture has been principally made in medium-sized or small gardens, the owners of which have become very fond of Tomatoes, and are, besides, justly proud of their productions. Many of these have grown profitable crops during the summer and autumn, and, provided they can command sufficient heat, there is no reason why they should not grow them during the winter also. Ornamental and useful they will undoubtedly prove, and this cannot be said of the majority of the ordinary occupants of our houses during the winter months.

Cuttings may be rooted or seed may be sown at the present time for the winter and early spring crops. The former should be well-ripened top shoots, taken off about 6 inches in length, trimmed at the lowest joint, dibbled in thinly round the sides of well-drained 6-inch or 8-inch pots, and placed either in a warm frame or a hand-light in a heated house. They should be watered in and be kept moist, but not saturated, and should not be damped over the foliage; and if much moisture condenses on the glass, air should be admitted for a short time every morning in order to properly dry the glass and foliage. They require to be shaded from bright sunshine till rooted, after which the plants must be gradually exposed to sun and air. The cuttings to be preferred are the strong yet well-matured tops of plants grown under glass; and those to be avoided, as being liable to damp, are the gross shoots often formed on plants grown in the open. Light loamy soil is suitable for cuttings or seeds. The latter may be sown thinly either in pots or pans, and placed in heat till germinated, after which the plants require to be disposed near the glass to make them sturdy. Thin out where at all crowded, and when the rough leaves are fairly visible pot singly in 4-inch pots, or in pairs in 6-inch pots, sinking the stems up to the seed leaves. This will tend to keep them dwarf, and the buried stems rooting freely materially strengthen the plants.

Various methods of fruiting Tomatoes are adopted, these being, or ought to be, in accordance with the intended sites. We have fruited them singly in 11 and 12-inch pots, or in pairs in larger pots, in any rather flat common boxes available, and planted out in ridges of soil as we treat Cucumbers. They are grown on the front side and central stages, and staked, or in the two former positions tied to wires disposed across the roof or ends as the case may be. We have also utilised the back walls of forcing houses for the purpose. In each case the result has been most satisfactory, and what we can achieve is equally possible to others if they choose to make the attempt. As compost we prefer roughly broken turfy loam with a liberal addition of decayed manure, but it is possible to grow excellent crops of fruit or plants rooting in ordinary well-enriched garden soil. It should always be remembered the Tomato loves good living, and, no matter how planted, is benefited both by frequent supplies of liquid manure and occasional top-dressings of rich compost, the latter being quickly taken possession of by the roots. Those who are unable to procure farmyard liquid manure are advised to give artificial manure or guano a trial, using these at the strength recommended by the vendors.

Although our plan is to grow and fruit the young plants with single stems, rubbing out all side shoots as they form, and stopping beyond the second or third bunch of bloom, and allowing the leading shoot following to extend and fruit, this is not necessarily the only or best method; but as a rule heavy crops can be had in this way without unduly shading the other occupants of the house. Unless the house is devoted principally to them they should be disposed at least 2 feet apart; but if they are of primary importance and plenty of root room is provided they may be planted closer. If preferred fewer plants may be thus grown, these being disposed 2 feet apart, and second growths from the base may be laid in and fruited. It is also easy to fill a house with one or two plants much after the manner of trained Cucumbers. For this method plants that have been previously fruited in pots or boxes are available. These should have their balls slightly reduced, and be shifted either into larger boxes or small pits about 2 feet square and as much in depth, which may be formed with loose bricks, allowing room in both instances for top-dressings. When this reserved space is filled further top-dressings may be given if a rim is formed with slates or boards in the first instance, or more bricks in the other. Such plants, if kept thinned out and stopped occasionally beyond the bunches so as to gradually occupy the allotted space, prove very remunerative.

From the commencement in every case the plants should never be allowed to become dry at the roots, and should receive light airy positions as near the glass as possible. Syringing must be avoided, and at times when many flowers are expanding the fruit may fail to set unless the atmosphere of the house be kept rather dry. We grow a variety of fine-foliaged plants and Ferns under our Tomatoes, the temperature of the house ranging on most occasions from 55° to 60° by night to 60° to 65° by day, the ventilators being slightly opened for a short time towards the middle of every mild day. In this manner, and by attending closely to watering with tepid water varied with liquid manure, and top-dressing whenever exhaustion is apparent, that healthy growth may be maintained which may be relied upon for perfecting moderate crops throughout the winter and spring, or till such times as the house may be wanted for other purposes. We make three annual sowings; the first in January for plants to be fruited in pots during April, May, and June; the next in April for plants to be fruited in boxes in Peach and other somewhat cool houses during July, August, and September; and the last in August or early in September for the winter supply. Any fruits of the late autumn crop there may be unripe in October are cut and hung up in bunches in a warm house to ripen, and these and any we may cut green at the end of September from the few we have on the open walls and ripened similarly prove of service in maintaining the supply till the house-grown produce is fit to use. Tomatoes may also be ripened in boxes placed before the kitchen fire whenever convenient, or on a rack at a safe distance above the fire.

A difficulty is frequently experienced in setting good crops during the dull autumn and winter months even with notoriously free setters. Every care should be taken that the plants receive no check in any way, and by closely rubbing out all superfluous growth, the bunches of bloom will be encouraged to develop strongly. A drier atmosphere maintained and frequent smart taps given towards midday or about an hour after air has been given will distribute the pollen and insure a good set. If this fails the blooms may be lightly touched over with a camel's-hair brush. We invariably secure good sets; in fact find it necessary to thin out the bunches, as a constant if comparatively light supply is preferable to occasional gluts, which result if extra heavy crops are allowed to mature at one time.—W. E.

THE NATIONAL CHRYSANTHEMUM SOCIETY - THE DISQUALIFIED EXHIBITS.

THE recent disqualification must in a great measure be attributed to the ambiguous manner in which the schedule is framed. For several years past various classes were stated to be for "blooms of any *large flowering* variety or varieties," and what is understood to be such have been shown with success. This year it reads the same, but a footnote is inserted at the bottom of the amateur classes as follows:—"Only the varieties included under the head of early-flowering in the Society's Jubilee catalogue, 1896, can be exhibited in the foregoing classes." This apparently was overlooked or misinterpreted by the various exhibitors.

Among the early-flowering varieties given in the catalogue very few, if any, can be called large-flowering, neither do they bloom in September. The footnote should have distinctly stated that the *whole* of the varieties exhibited at this show should be as given in the catalogue. But is it advisable to attempt to encourage the cultivation of these small-flowering early varieties except it be in the natural or bush form?

If such stipulation is considered a wise one, then the selection must be compiled with more care than has been displayed in the Jubilee catalogue, for several of the finest and largest flowering varieties are omitted. Two in particular I would mention—viz., Queen of the Earlies and Barbara Forbes. These were sent out as early-flowering varieties in the spring of 1896, and were shown at several of the early meetings of the N.C.S. in the autumn previous.

The late Mr. W. Piercy, no mean authority, repeatedly expressed the opinion that Queen of the Earlies was the finest early white in existence. Two seasons ago it was pronounced by Mr. W. H. Lees, who then grew it, to be immensely superior to Madame C. Desgrange. Barbara Forbes received the first and only F.C.C. awarded by the N.C.S. throughout last September, yet, strange to relate, neither of these varieties is to be found in the early flowering list of the N.C.S., and for this reason were disqualified by the judges (to whom no blame can be attached) at the recent exhibition. That they were known to the Catalogue Committee is proved by the fact that they are not to be found in the general section.

It is worthy of remark that several varieties which have repeatedly been exhibited and catalogued by all the most important trade growers are omitted from the catalogue, whilst quite two-thirds of those catalogued have not, and never will be, listed by the English trade grower. Annie Heard, a single, and perhaps the prettiest and most graceful white we have, was certificated in 1895 by the N.C.S. and R.H.S., and a portion of the Committee of the former are the compilers of the catalogue, and yet it is not to be found in the list of selected varieties. If not worth inclusion in the list, why certificate it? What weight do the Catalogue Committee themselves place upon the certificates?—W. J. GODFREY.

FLOWERS FOR VASES.

THE highest philosophy leads to simplicity. What a time elapses before we recognise that fact. All Nature is essentially simple, and gardeners, as waiters on Nature and fellow workers with her, ought to study simplicity above all things. In nothing is this so true as in the arrangement of flowers. Some years ago we entered a cycle of vulgarity and ugliness in the floral decoration of dining tables. It is true that flowers, no matter how barbarously treated, always retain their individual beauty. That we cannot destroy, but we can and often do mar it, and at that time we certainly did reach the lowest level of decorative floral art, while the labour and time spent in filling and refilling receptacles of tin or other material was just so much time wasted. Happily, we have reached a period when Nature is more left to speak for herself. Without doubt we shall always have those who consider the labour and ingenuity spent on arranging flowers as some measure of their beauty, but a freer and healthier tone prevails generally. In fashionable bouquets for the hand this is especially noticcable, for while a large amount of artificiality is retained it is an artificiality of a more generous nature, individual blossoms being less crushed together, and the rarer ones brought so prominently forward as to show their beauty on every side.

Bouquet-making, however, is comparatively limited in extent, and does not appear to be growing as a feature of garden work. Room decoration with flowers, on the other hand, is spreading to an alarming extent, using that expression from a gardener's point of view, for the market grower and the middleman who disposes of his goods must look with lively satisfaction on the spreading downward tendency of this innocent and pleasure-giving taste, while all must cordially view the increasing love for flowers with appreciation. But from the gardener's look-out it becomes a question of much importance, as the prevailing tendency with all extra demands is to expect them to be met without any corresponding addition to the means for doing so. So it is in this case; summer and winter, spring and autumn, flowers are wanted, and the gardener is left to find them as best he may. I am afraid too many gardeners at the present day must think of the doings of Pharaoh the hardhearted when he ordered his Hebrew subjects to gather their own straw without lessening their tale of bricks, and apply the case to themselves. Certainly, it now-a-days requires much ingenuity to make ends meet.

I must return to my opening sentences and reiterate the fitness of simplicity. Too often very much more material is employed in vase-decoration than is required. To be orthodox we must have a border of Ferns and a complicated arrangement of blossom and greenery firmly packed so as to cover every particle of the space inside this Fern border. This is merely stereotyped conventionality, and it is wasteful. I see no reason why a vase may not be so arranged occasionally, or always if you like; but to fill half a dozen or a dozen glasses in one room in this fashion, and further to carry the same arrangement out in every occupied room in a house, is beyond good taste to say the very least. When we call to mind that these flower receptacles may be of all sizes and shapes—tall trumpets and flat wide-mouthed dishes, dainty little vessels with narrow openings, or classical pieces of various shapes—the system condemned becomes so much the worse. The vases gardeners are often called on to decorate are unsuitable, and so far it is difficult to carry out simple arrangements. I am also aware that the taste of their owners has to be studied, but outside these particular instances lies a vast field to work in with effect.

Considering the matter in a practical manner, I have at once to concede that no strict rule can be laid down to be followed with advantage. But I may be allowed to offer some hints, which I trust may be found not altogether unworthy of consideration. The first hint I would give is to consider that flowers do not grow in bunches. A bunch of flowers tied together is a reasonable mode of carrying these in the hand, but not necessarily the best way of showing off or enjoying their individual beauty. This brings me to hint that the shape and size of the receptacle should be studied. A large trumpet-shaped glass and a low, wide, and open dish require widely different treatment. The latter might at present be effectively and simply filled with flowering shoots of Pansies or Violas; or Sweet Peas, and Mignonette make a charming mixture; or going to more refined (?) material, we may employ double Ivy-leaf Pelargoniums, sprays of Heaths, Begonias, Lapagerias or Stephanotis, in each case using sufficient foliage of Pelargonium or Begonia or Sweet Peas for a setting without having to add Ferns. The idea is to have flowers charming in themselves, and so arranged as to show their beauty easily. Then if we take the tall trumpet we must decide on bold flowers at once, and, as in the case of the flat dish, a certain flatness of arrangement is called for, so in our tall glass any approach to flatness must be avoided. If you use single Dahlias, cut shoots with leaves, buds, and open blossom, and arrange as freely as the plant itself grows. If Gladioli be selected, cut with foliage attached, and let the spikes be fresh, young, and bold. And so on with any other flower chosen, let them always be massive if possible, and stand free of each other.

For medium-sized glasses a certain degree of airiness should prevail. Roses are not particularly "airy," but by cutting with long stems, keeping the foliage intact, and adding sprays of Jasmine on the common Clematis, lumpiness is easily avoided. Very suitable for such glasses are the Japanese Windflowers, which may either be used by themselves or intermixed with Marguerites, Oxeye Daisies, and Sweet Peas. The most charming of all flowers just now are Picotees and Carnations. These are much better arranged in smallish vases, first inserting in the water four or five healthy cuttings (foliage), and then adding a few long-stemmed shoots cut off just as they grow. For small glasses I think, as a rule, that fine single blooms are much the best an Eucharis backed with a spray of Maidenhair Fern, an open Gloire de Dijon with foliage and bud, a truss of double Ivy-leaf Pelargoniums with its own foliage, are examples of what I mean.

These are all flowers common at present that are mentioned, but the same remarks are applicable to flowers at all seasons. Notwithstanding the great variety of flowers we have to choose from, gardeners have restricted themselves to a few well-known kinds, and, unfortunately, have treated them all very much alike; no matter whether a flower grows in lowly fashion like a Pansy or on tall shoots like a Chrysanthemum, the blossom itself is snipped off with an almost unvarying length of stalk. This should not prevail. Colours of flowers are often badly selected for effect. Take the Chrysanthemum as an instance, and we have a great variety of shades and colours which are not uncommonly mixed together when cut. Red, white and yellow Chrysanthemums are almost enough to employ for cut purposes, and they should, as a rule, be cut with long stems, and arranged thinly in large vases, leaving foliage and buds to show. Single Anemones are grand for spring, but are very seldom met with. Many wayside or wild flowers are lovely. Forget-me-nots, Bugloss, Marsh Marigolds, Oxeye Daisies, Cornflowers, Harebells, Grass of Parnassus, and Wild Roses, are names that occur at the moment.

Just a line or two more to protest against the general employment of Maidenhair Fern to the exclusion of other foliage that is equally beautiful when appropriately employed. For many purposes the Maidenhair is of unique value, but for decorating vases in general it is much better to rely on foliage belonging to the flowers used. With even more force does this apply when decorators pass the leafage Nature has bestowed on plants and ransack the pinetum for material.

In decorating dinner tables, I do not think anything is more suitable than rather small glasses to be filled with good flowers. At the same time I would not like to say anything against laying cut flowers on the cloth provided it is done without anything hinting of artificiality. I mean I would not make any arrangement as to shape other than just laying on the flowers as they are cut. If the flowers are poor in character some other means of using them should be employed.—S.

WESTONBIRT.

UPWARDS of twenty-four years ago, or to be exact, in the issue of the *Journal of Horticulture* dated July 31st, 1873, there appeared an article descriptive of the beauties of Westonbirt, in which the writer stated it as his opinion that that was the first extended reference which had been in the pages of this or any other gardening paper, and so far as can be found no notes have appeared in these columns since then. This neglect is more than surprising when the undoubted magnificence of the estate is borne in mind. Its palatial mansion, lovely pleasure grounds and flower gardens, well-equipped houses, and superb arboretum are each worthy of an article to itself. No general notice could possibly do justice to either of these individually, much more to the whole, but an effort must be made in the limited space at command. The writer of the references to which allusion has been made spoke in highly eulogistic terms of the place then, when it was, so to speak, in its infancy, and more than corroboration can be added now. On every hand there is beauty either of Nature herself or of the art of man. Then the occupier was the late R. S. Holford, Esq., now his son, Captain Holford, Equerry to his Royal Highness the Prince of Wales, is the fortunate owner.

In justice to the former of these gentlemen it must be placed on record here that it is to him the credit is due for this worthy addition to the list of the "Stately Homes of England." The estate has been in the possession of the family for several generations, but it was not until Mr. R. S. Holford came into the property that a determined effort was made to improve the horticultural and the arboricultural departments. His knowledge in each of these subjects was most profound and took an eminently practical shape. To-day Capt. Holford has the same interest, but with considerably less time to devote to estate matters. Trees there are of his planting, and in their placing it can readily be perceived that the taste of the father has been inherited by the son. This is as it should be, for it may be taken as a criterion that the estate will, so far as it is in his power, be maintained as it has been and as its beauty demands that it should be.

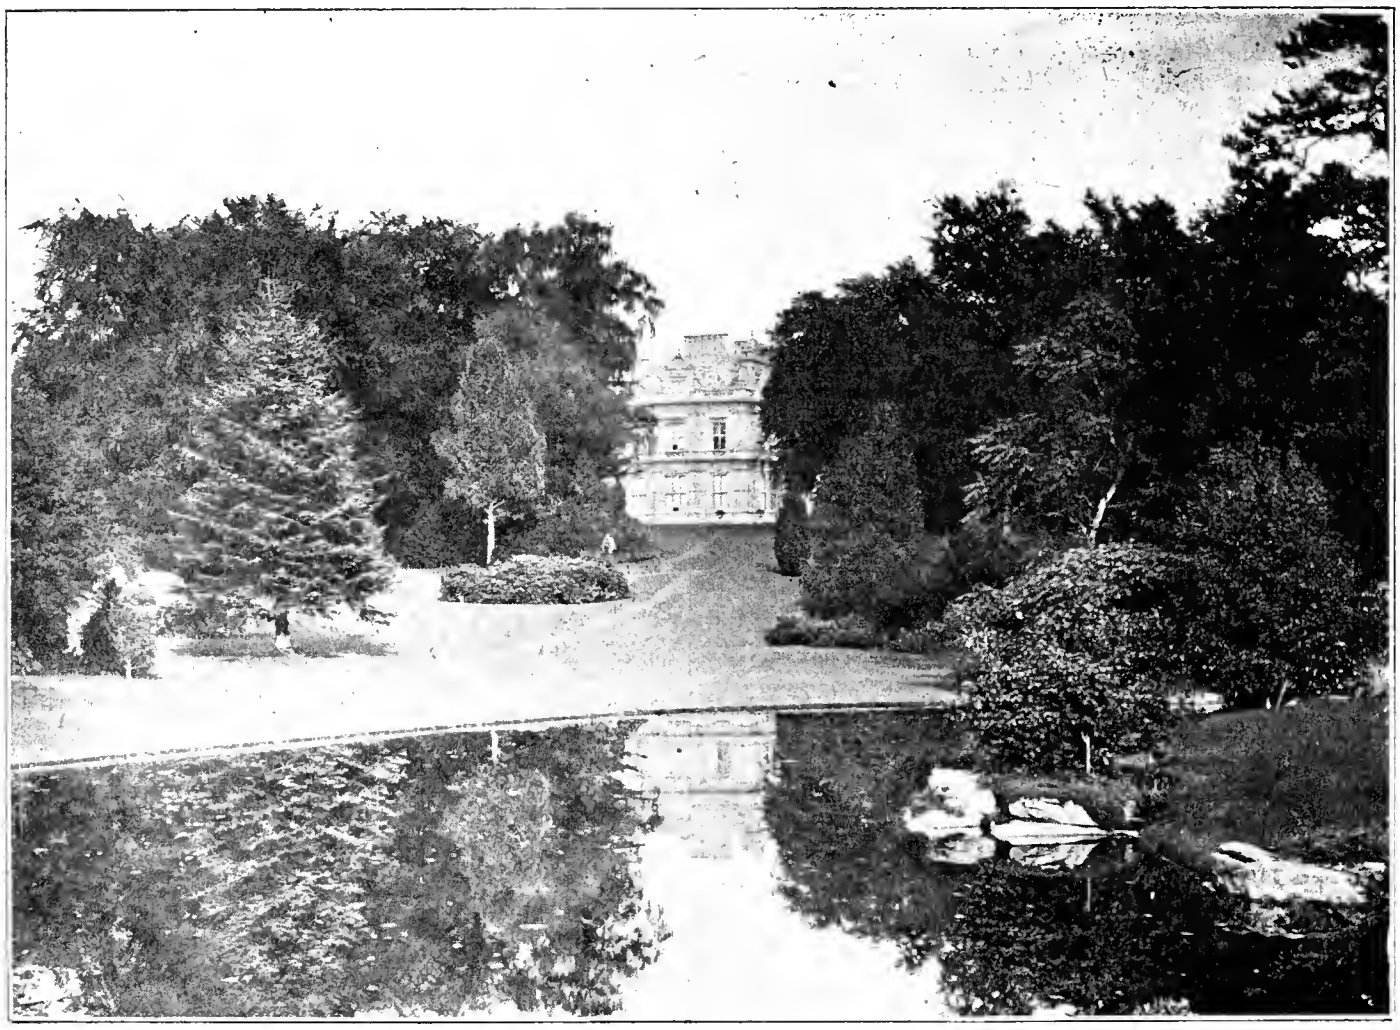

FIG. 38.—IN THE PLEASURE GARDENS OF WESTONBIRT.

Perhaps the feature which strikes the visitor to Westonbirt the most forcibly is the exceptional artistic taste seen on every hand that was displayed in the planting of the trees in the pleasure grounds about the mansion. Knowledge of plant life and of tree life is stamped in every clump, in every glade, and in every dell. Each tree and bush is neighboured by those of different character, though the harmony is never strained in the slightest degree. One can see at a glance that the planter was quite alive to what each tree or bush would eventually attain, with the consequence that every one, while showing itself to the best advantage, assists in emphasising the points of its neighbours, whether they be comparatively close to or distant from it. When the changes were commenced there was flat meadowland, now there are rockeries, lake, shrubs, soft lawns, and handsome trees in about the most charming 30 acres of pleasure grounds it has been the writer's fortune to see.

From an arboricultural point of view the interest engendered at the outset is maintained to the end, for the variety is remarkable. There are to be seen almost all kinds of Coniferous and other trees, and in the majority of instances there are perfect examples of each. Specimens of several represent the products of the first consignments that came to this country, and amongst them may be noted Wellingtonia gigantea and Cedrus atlantica, with scores of others of which mention cannot be made. The Conifers are of singular beauty, the boughs sweeping the ground and rising gracefully to the summit without a break. The Liquidambers, the Tulip Trees, the Oaks, the Acers, with many besides, are all excellent amongst the deciduous kinds, and are no less beautiful in their way than the Conifers previously noted. One might spend days amongst the trees noting the stature of a noble Cupressus here, and the spread of branch of the Cedrus deodara yonder, the graceful contour of a Douglas Fir, and the handsome leafage of the Japanese Maples, but such a course would need the eye and mind of a specialist in arboricultural craft. The results of such an inspection of the trees here and at other places where kindred work was done—Tortworth for example—would be valuable, and of more than passing interest.

Returning now to matters pertaining more of a horticultural character, but with no apology for the digression into the world of trees, we find an individuality marking Westonbirt as different from most other estates. In the planting of a small border of shrubs, in the formation of the rockeries, in the making of the lake, in the throwing up of terrace on terrace, judgment, practical knowledge, skill, and taste have all been combined, and with the happiest results. Glance at the illustration (fig. 38), which in a peep from the lower ground between the trees, shows the mansion on the rising terraces. It is a pretty picture, and only one of the many that abound on all sides. From one place a glimpse may be had of the lake, with its rocky sides and fertile borders, while in another an opening in the verdure will show some noble tree or beautiful foliage or flowering shrub. A walk is one of never-failing interest, for "at every step fresh beauties greet, and glorious scenes unfold."

The planting of bulbs in the grass near the edges of beds and borders has been very extensively carried out, and one is always meeting something fresh. There are Daffodils for the spring, with Snowdrops, Aconites, and Dutch Crocuses; while hardy Cyclamens, Crocus species, and many others thrive luxuriantly. Year after year these grow and spread, but their flowers in the soft coolness of the grass carpet are always fresh, always admired. It seems a great pity that more of this system of planting is not followed by those in charge of the pleasure grounds of estates. We might go on about this section at great length to the exclusion of other features of interest and beauty, but this would not be carrying out the determination made at starting, to do the best we could for all.

The mansion, which was built by Mr. R. S. Holford, is an ornate structure, and if one were writing for an architectural publication would supply an abundance of "copy," as it is it must be passed with a cursory glance. The view of it shown in the photographic reproduction (fig. 39), to secure which the operator stationed himself on the lower terrace, will convey to readers an admirable idea of its general character, and of its imposing magnificence. It is built of Bath stone, and it need scarcely be said that the rooms within are commensurate in dimensions with what the exterior would lead one to suppose. London readers, and many country ones too, will be familiar with Dorchester House, Park Lane, which was erected by the same gentleman as Westonbirt House, and with it passed to Captain Holford. The smoke of thousands of chimneys has

taken the freshness from the London house, but the country one is clean and bright owing to the purer atmosphere.

To the left of the mansion, as shown in the illustration, and attached thereto is the conservatory, which is of considerable size. A handsome corridor leads from the interior of the house to the conservatory proper, and both are of course kept stocked with plants of all the kinds that will thrive. From the roof depend many climbing plants, of which the most attractive just now is undoubtedly Bougainvillea glabra. The cool atmosphere of the structure evidently suits it splendidly, for the flowers are much finer, both in respect of size and colour, than when, as is so frequently the case, the plant finds a home in the intermediate house, or even the stove. The Palms in here are numerous and varied, while flowering plants are introduced in suitable places to brighten the structure, which is a trifle dark in colour overhead to show leafage off to the best possible advantage; but this cannot well be helped, and the best that can must be done.

In the foreground on both sides are flower beds. These are not very numerous except in the garden enclosed by walls especially for them, and are at a discount, but there was one specimen with a spike of three handsome blooms. We shall look forward to seeing some of the older seedlings in James' Street next year.

Though Orchids are not grown so extensively as in some establishments that have been visited, they are constantly being added to by Captain Holford, who is deeply interested in them, so eventually there will not only be quality, as is the case now, but quantity in addition. As with the Amaryllis, flowers are at this moment conspicuous by their absence, but a glance at the labels shows how judicious has been the selection with a view to securing the best. All the Cattleyas, Dendrobiums, Odontoglossums, Cypripediums, and others are in splendid health, and will render a good account of themselves in the years to come if the present promise is fulfilled. Coleuses, Begonias, Ferns, Crotons, Solanums on the roofs, with all the customary greenhouse and stove plants, are thoroughly well grown, many of them in considerable numbers. When this visit was paid the first three were making beautiful displays in their respective houses. Nothing advantageous would accrue to the naming of varieties, so we will advance another step towards the conclusion of our tour round Westonbirt.

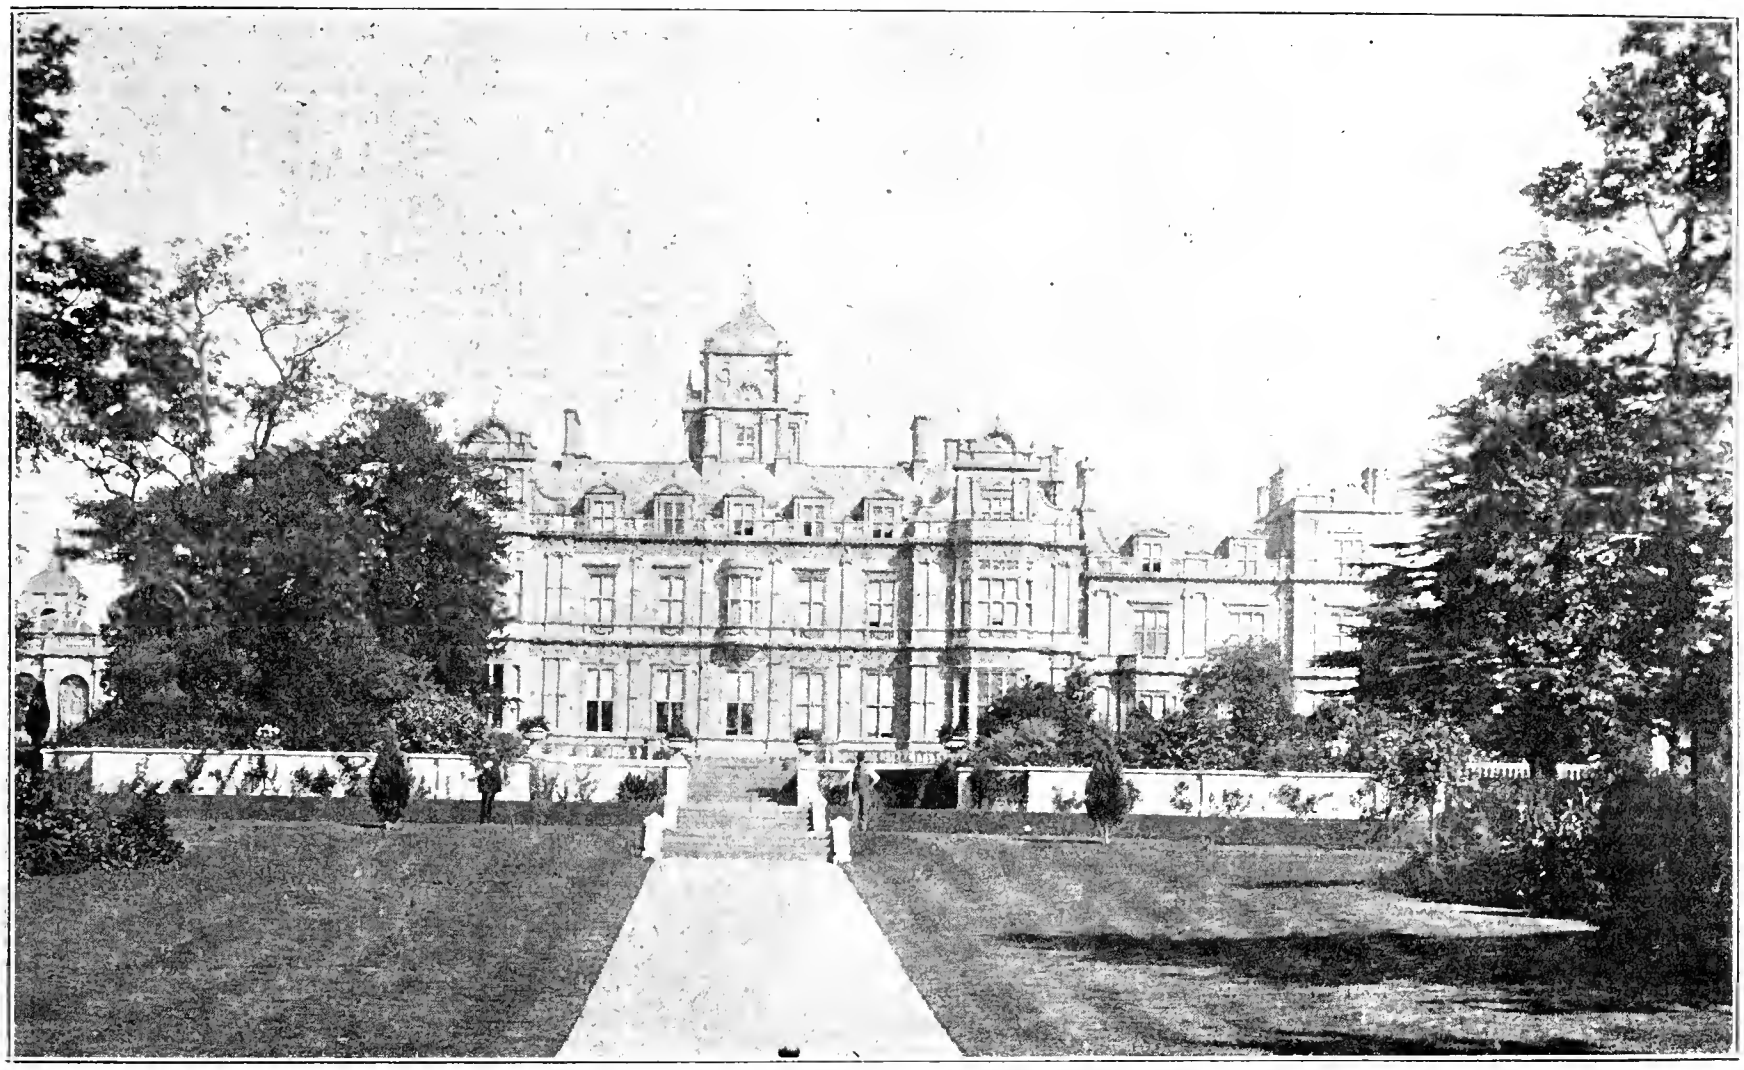

FIG. 39.—WESTONBIRT HOUSE.

where some beautiful flowers may be seen. Outside of this the beds are occasional, and are occupied generally with one or two kinds of plants. To enhance the charm they are not close together, but are separated by broad sweeps of lawn or clumps of flowering and foliage shrubs. As the customary plants are utilised in the flower garden they will not be enumerated here, as it would simply be taking space unnecessarily. The stone walls encircling it are clad with plants of all sorts, including Berberis, Vines, and Ampelopsis amongst others, to see which in their beauty would mean a visit towards the end of October, when the leaves have taken on their autumn tints. This, indeed, would be a very suitable time to visit the demesne, as the trees and shrubs would then be very much more beautiful than they are now, for, according to the head gardener, Mr. A. Chapman, the colouration assumed by many is intense and really superb.

The number of structures devoted to the cultivation of plants is very large, and as the whole of them are in one enclosed space they are convenient for working. Of all the plants grown, the greatest interest is centred on the Amaryllis, of which the collection is certainly one of the finest in the country. Frequenters of the Drill Hall shows will remember the grand displays that have been made by the Westonbirt plants, about whose flowers there is a distinctive air of substantiality and quality. The colours, too, are distinct from many of those grown elsewhere. There are thousands of seedlings from less than one year old upwards, and some interesting results are anticipated in the future. All of them are from Mr. Chapman's fertilisation. Just at present flowers

It is apparent that the soil is admirably suited to stone fruits, for they crop wonderfully; and this is the case year after year, both indoors and out, without any very special attention. Plums are, perhaps, the lightest this season, but these are far better than in less fortunately situated places. Pears on the walls are also good, but Apples are not quite up to the average. Melons, Cucumbers, Grapes, and Tomatoes all have a considerable amount of space allotted to them, while Peaches and Nectarines are extremely numerous. The vegetable gardens, of which there are three, are well stocked with all kinds that are required. None could be selected as being markedly superior to its neighbours, for all were in creditable condition. A portion of the smallest vegetable garden is devoted to reserve beds of hardy flowers, whence one may cut continuously for several months in the year. Most of them are herbaceous, and in the majority of instances a bed is utilised for one kind only.

After having inspected the home gardens we made our way to the arboretum, which is situated about three-quarters of a mile from the mansion. Here may be seen thousands of trees of the most varied kinds in the rudest of health. There are Conifers by the thousands, as well as evergreen and deciduous trees, and nowhere can a bad specimen be found. Obviously, some are far better than others, but all are interesting and many extremely rare. The expert who examines the trees in the pleasure grounds would find himself in a paradise in the arboretum. The area was not known by Mr. Chapman, but by the many grass drives by which it is intersected it must be of very great extent. The drive through the park

to the shade and coolness beneath the trees here must be extremely pleasant for the visitors to this lovely domain. From hence we made our way towards the quaint old town of Tetbury, delighted with the beauties of Westonbirt, and convinced that the day had been most profitably spent.—H. J. WRIGHT.

LIVERPOOL AND DISTRICT FRUIT REPORTS.

FOLLOWING my system of last year I am sending the usual fruit reports from our district, taken from gardens where hardy fruit is well grown, and where the collections are kept pretty well up to date. The situations are varied, and may be taken as fairly characteristic of the districts mentioned.

CLEVELEY, ALLERTON.

Mr. Cromwell has planted extensively of late years, and has now a grand collection of young pyramids in full bearing. Early kinds of Apples are much the best, this being attributed to the fruit having been set prior to the severe frosts the third week in May, which seemed to destroy the blossoms on late growing kinds. Pears in the open are better than on cordons on walls, although much below the average. Plums, nil. Strawberries have been excellent, the varieties grown being Royal Sovereign, Scarlet Queen, President, and Duc de Malakoff. Stevens' Wonder Mr. Cromwell has not succeeded with, either in pots or planted out. Of Raspberries Superlative is fine. Blackberries increase in favour, Mr. Cromwell advising their cultivation most emphatically for preserving with Apples. The arch, 30 yards long by 9 feet wide, is just now clustered with ripe fruit, from 20 to 30 lbs. being gathered on the 6th inst.

ALLERTON PRIORY.

Mr. Craven grows hardy fruit to the best advantage, although the trees are very old. Apples are moderate, some good, notably on standards. Pomeroy of Lancashire (a highly coloured local variety, and wonderful cropper), Warner's King, Lord Derby, Ecklinville, and King of the Pippins. Pyramids are better—Lane's Prince Albert, Ribston Pippin, Worcester Pearmain, Potts' Seedling, Cox's Orange Pippin. Cellini, usually good, is this season a complete failure. Plums and Damsons are failures, Cherries almost so. Gooseberries and Black Currants good, Reds fairly so; Pears thin, Jargonelle, Beurré de Amanlis, and Durondeau being the best.

CALDERSTONE, AIGBURTH.

Apples are a fair average crop, Pears are the same, Mr. Tunnington praising the good shelter from the cold winds and May frosts. Peaches and Nectarines outdoors are carefully cultivated, in splendid condition in every respect, the crop being abundant, showing what can be done in this respect at the present time, but wasps are most troublesome. Apricots in the open are more than half a crop, but Plums are a failure. Small fruits have been good.

ELM HALL, WAVERTREE.

Hardy fruit has been much improved since Mr. Bracegirdle came into charge. Apples are a good crop, especially Warner's King, Keswick Codlin, Suffields, Grosvenors, Ecklinville, Stirling Castle, Bismarck, Lane's Prince Albert. Of dessert Irish Peach, King of Pippins, and Ribstons are the best. The Russet section is not so plentiful. Pears are fairly good, Jargonelle, Marie Louise, Louise Bonne of Jersey, Durondeau, Clapp's Favourite, Pitmaston Duchess, and Winter Nelis being fine. Plums and Cherries have been very scarce. Figs, Apricots, and Peaches slightly protected very good. Small fruits have been plentiful.

HIGHFIELD, WOOLTON.

The Apple crop, always good with Mr. Haigh, is this year excellent. Pears in the open are a failure, but there is a good average crop on walls. Plums are in the same position. Of small fruits, Gooseberries, Red and Black Currants have been half a crop, with Raspberries quite up to the average, and Strawberries very good.

KNOWSLEY HALL.

Apples are very good, the best being Lord Derby, Lord Suffield, Bismarck, Schoolmaster, Cellini, Potts' Seedling, Yorkshire Greening, Ribston, Blenheim, and King of Pippins. Pears are under average in quantity and quality. Bush fruit has been a fair crop, whilst the best Strawberries have been British Queen, Royal Sovereign, Leader, a grand addition; Latest of All, and Oxonian. Plums, as in most places, are a complete failure. Mr. Doe has the trees in capital condition.

COURT HEY, BROADGREEN,

Apples are a fine crop throughout; Pears very poor, the fine cordons on the wall have suffered much from May frosts. Bush fruits have been a very fair crop, and Strawberries good.

BLACKLOW HOUSE, ROBY.

We have an excellent supply of all kinds of Apples, many of which have had to be thinned. Bramley's Seedling fruiting for the first time promises to be a welcome addition. Pears are not a heavy crop, but of good form, and with a fine September will improve greatly. Such sorts as Citron des Carmes, Beurrés Capiaumont, Diel, d'Amanlis and Bosc, Hacon's Incomparable, Magnate, Marie Louise, Prince Consort, and the delicious Doyenné du Comice, are all well cropped. Gooseberries, all kinds of Currants, and Strawberries have been first-rate, but Plums and Cherries almost a failure. Liquid manure has had to be used freely, as the majority of our trees are bordering on the half century.

OAKLANDS, SPITAL.

Mr. Ranson, who has seen twenty-three years' crops gathered in, says this season's is certainly the worst. Apples are a first-rate crop and fine fruit. Pears being about a third. This is a noted Damson and Plum district, but the crop is almost nil for miles round, a hundred fruits of the latter having to suffice for Mr. Ranson in place of some 3 or 4 cwt. in former years. Strawberries and Raspberries have been capital, but failure must be written of the Currant crop.—R. P. R.

VIOLA NOTES.

VIOLAS to bloom well over a lengthened period require a rich and moist soil, not necessarily wet, but one which will support the plants in dry weather. Even a light, well-drained soil, rich in humus by liberal dressings of manure and leaf soil, will give stamina to plants in dry weather, enabling them to withstand its effects with better results than are produced from plants in a heavier-textured soil. Violas, it must be borne in mind, are not marsh plants; they grow on knolls, or slopes, or in ground free from stagnant water; therefore, though a moist soil be desirable, it should be well drained, moisture being afforded by supplies of water in a prolonged dry period.

Ground for Violas ought to be trenched or stirred to a depth of 15 to 18 inches, as good soil admits. It is of no use going down with a view to bringing to the surface matter which, before it can be available as food for plants, requires amelioration by atmospheric influence and an addition of organic substance. Trench the ground in autumn, putting in some partially decayed vegetable refuse not further from the surface than a foot; and if the ground will not admit of being turned up deeper loosen the under strata, placing the manure upon it, throwing the surface rough for the winter. In spring dress the surface with leaf soil or manure

Plants raised from seed grow more upright and do not branch nearly so well, and are not, for a time at least, so floriferous as are those from cuttings. Seedlings are not good the first year; it is not until the plants are cut down that dependance can be placed upon seedlings for a full display: hence I do not advise the plants to be raised from seed except for the origination of improved varieties. Those, however, who wish to raise plants from seed may sow the seed the middle of August up to early September in light rich soil in a sheltered situation, pricking out the seedlings 3 inches apart in a sheltered spot in October, and planting them in March or early in April.

Cuttings give the best and most floriferous plants. Take the cuttings towards the end of September or first week in October. Choose for them a sheltered border—under a low wall or fence—and moderately rich soil, made fine and level, surfacing with a thin layer of sand. Let the cuttings be of the shoots which spring from the base of the plants, not using the exhausted flower growths, and about 2½ to 3 inches long, pricking them in about half their length 2 inches apart, firming them well in, completing with a good watering. In a very bleak position the cuttings may be put in a frame and wintered in every respect like Calceolarias.

Plant them out in spring before dry weather sets in, and in no case defer their planting until the usual time of bedding, for Violas and Calceolarias are not able to contend with drought if it come upon them before their roots have obtained a good hold of the soil. Short duration of bloom and sudden collapse are due to late planting.

Plants from cuttings made in early October will give an effective summer display, but not unfrequently Viola beds become seedy in autumn, as, indeed, all plants do that have been in a high state of perfection during the hot summer months. For a late or autumn bloom, cuttings may be put in in May or June, affording them shade. An amateur tells me (and I have seen) how to root Violas and Pansies in summer—namely, put them in between the rows of early Potatoes where the cuttings are shaded from the sun, lift the plants with balls the first showery weather after rooting, and plant them where they are required to bloom. For a spring display, or rather early summer, for it is not until May that Violas are in their beauty, the cuttings should be put in the second week in August, and be in their flowering quarters in October. An earlier bloom will be had by wintering the plants in frames, planting out during March. Potted and plunged in cocoa-nut fibre refuse they stand well, and if in the open a top-dressing of the same material is of great assistance to the plants. Plants divided in October and then planted will afford a good early display.

Violas stand wet well, better perhaps than any other flowering bedding plants, and succeed in summer in high cold situations, where more tender subjects do not have other than a starved appearance. Being moisture-loving plants they are benefited by a top-dressing in summer, for if mulching has the property of retaining heat in winter, it possesses equally the power of retaining moisture in summer. Soak, therefore, Viola beds with water in dry weather before the soil becomes hard and cracked if heavy, or dusty if light, applying the water to the roots rather than overhead, and mulch with short manure, which will be hidden by the foliage. Neater than manure and as good is cocoa-nut fibre refuse, and if this is placed close up to the plants they will produce fresh shoots freely, which will root into the mulching.

To keep the plants in flowering order through the summer it is necessary to cut off the seed pods and to thin out the old stems, thereby encouraging young growth; and this attended to before the plants are exhausted, frequently going over the beds, attending to them with water and weak liquid manure in dry weather, we shall find Violas continue blooming from early spring to late summer in as good a state of perfectiveness as most descriptions of flowering bedding plants.—G.

A VISIT TO WORCESTER.

No visitor with an hour or two to spare and the slightest pretension to an interest in horticulture, would ever think of visiting the ancient city of Worcester without looking in at the nurseries of Messrs. R. Smith and Co., which are situated at St. John's. The people of Worcester find pleasure in styling themselves as of "the City of the Faithful," an honourable title to which we fancy we have heard the Exonians lay claim. But whether or no they are justified in this matters little to readers of the *Journal of Horticulture*, who are satisfied with the knowledge that the city has within its precincts such a famous nursery as that under notice. It is no establishment of Mushroom-like growth, but a business that has grown with the years and with the decades, and stands now renowned the world over for its Clematis, its hardwooded plants, its shrubs, and its fruit trees, with other things that one need not particularise in an introductory paragraph.

As the train rushed on its way towards the town the writer found himself wondering whether he would experience any difficulty in reaching the desired goal. But nothing of the sort need have been fancied, for it was quickly learned that trams ran frequently from the Great Western station yard to the gates of the nursery. The route is for some distance through many narrow strects, but after crossing the river a broad road bordered by trées is entered upon, and is considerably more pleasant, especially on a hot day in the summer. These few hints are given with a view to assisting other horticultural strangers who may purpose visiting Smith's. It may be said that the distance is about two miles, and thus a comfortable walk on a cool day, but rather too far under a blazing sun when the one or two hills that have to be mounted are taken into consideration.

When once St. John's is reached one finds oneself in a totally different atmosphere—the air being much purer, sweeter and fresher, than in the town just left. Such being the case, one could not be surprised at the charming effect the first entrance within the gates of the nurseries left upon the mind, for everything looks bright and healthy. A long broad walk stretched away in front of us, flanked by vegetation on each side, but we did not follow this, but bore away to the left in search of the offices and of a guide, both of which were speedily discovered. A rest and a chat here over gardening and gardeners occupied only about a quarter of an hour, after which we commenced our tour in real earnest, and inspected at the outset

The Glass Department.

The writer had had a sort of impression that, beyond Clematis and Heaths, nothing "great" was grown under glass, but in this was most hopelessly wrong, for there are Roses by the thousand, Pelargoniums, all kinds of hardwooded plants, Ampelopsis Veitchi, and others in enormous quantities, and all in splendid health. Naturally the Clematis took attention first, and as we passed through house after house, we ventured to wonder audibly how many were grown, and were astonished to find the stock was about eighty thousand. "Stupendous!" readers may think, and wonder where the whole of them find their way to. All ages are represented in various places; some have only just been root-grafted, and do not yet show any signs of growth. In another stage, the plants in about 3-inch pots had each a 3-feet stake that was clothed with clean, strong, healthy growth. These were packed pot thick in immense central beds, and on the side stages of several very long span-roofed houses. Beyond these two samples there are others of much greater age, and, of course, all the varieties for which the firm is renowned are represented.

The vast array of Roses in pots is almost as imposing as the Clematis, and the plants have the same desirable characteristics of health, cleanliness, and strength. Almost the whole of them belong to the Tea and Noisette sections, and of all there is probably a larger number of Maréchal Niel than of any other individual variety, though all the most popular ones are represented by hundreds, and even more. It is noticeable that at every few yards through the houses are standpipes with lengths of hose, so that water may be applied rapidly in any particular spot that may require it. Asparagus deflexus, A. plumosus nanus, A. Sprengeri, with Ferns, Dracænas, and other plants appreciated for the beauty or elegance of their leafage, receive more attention than is customarily devoted to them in nurseries, and prove by their condition that the treatment to which they are subjected is in every way suited to their requirements.

Let us now turn for a moment to the hardwooded plants, of which we will mention Ericas and Azaleas as two typical examples. Of these and others there are thousands, growing in houses, frames, and in the open air. Young plants and old ones are seen on every hand, the propagation being effected at home—indeed, Smith's is one of the few establishments where the increase of these plants is largely carried out. The growth is wonderfully sturdy and strong, and proves that the firm has made a speciality of something it thoroughly understands. It would be impossible to find anywhere a collection of plants in better condition than these. Azaleas are propagated by the thousand to meet the extensive demand, and beyond the new varieties, of which some are purchased each year to keep the collection up to date, there are no continental specimens on the place. Evidently the wants of these are known by the man in charge.

But we must proceed on our way, and note in passing the hundreds, even thousands, of Lapagerias, especially of rosea, of which there are some superb plants. Bouvardias constitute a business in themselves, to such an extent are they grown; while Gardenias, Ixoras, and Stephanotis, with Cannas, Crotons, and many others, receive attention in proportion to their importance, and the demand there is for them from buyers. None of these several plants are grown and arranged in houses for show, as is seen in most nurseries; they are grown for sale, and so excellent is the firm's reputation, that purchasers find no necessity to make their own selections—instead, they state their requirements, and rely upon having them fulfilled. It is probable that of the plants we have mentioned, the stock in the Worcester Nurseries is one of the finest and most extensive in the United Kingdom. Thousands of Pelargoniums of the various sections are noted in our walk round, for in these a very large trade is done, especially, we learned from our guide, in the North of England and across the border.

Flowers out of Doors.

When mention has to be made of the outdoor flowers we need not go farther than the Roses ere making a start, for of these there are about twenty acres, some in one place and some in another. Hybrid Perpetuals and garden Roses, of course, take up the major portion of the space, the Teas, as has been previously observed, being grown within doors. Standards and dwarfs, young and old, all have their place, and all are in capital condition. Despite the intense heat that had been prevailing for some time prior to this visit being paid, there were large numbers of beautiful flowers to be seen, from which, by careful selection, a box could easily have been found that would have done credit to any show. A noticeable quarter in this section was that occupied by the Crimson Ramblers, which by their magnificent growth and beautiful foliage, were conspicuous before all others.

Hardy plants of all kinds for rockeries and for beds or borders receive attention, and are grown in small hedge-enclosed gardens. In this department the most noticeable feature amongst the plants in bloom was the uniform excellence of the species and varieties. This, we learned, was due to the fact that a few years ago, when land was scarce, a thorough overhauling had been carried out, any that were at all inferior having then been lifted and thrown away to make room for others much more deserving of the valuable ground at disposal. No attempt will be made to mention names here, as herbaceous plants are familiar to all, and the most prominent will flash across the mind of the reader as these notes are perused.

Trees and Shrubs.

As the nursery occupies an area of 200 acres, or thereabouts, it will readily be recognised that there is plenty of room to grow shrubs and trees of all sorts and of various sizes, and this, despite the fact that 20 acres go for Roses, and considerably more than that for Asparagus, which is grown to a surprising extent. The specimen shrubs of all kinds on the margins of the main walk, which is rather over a mile in length, are splendidly grown, and demonstrate both the suitability of the soil and the cultural methods adopted. Hollies are of exceptional excellence in all stages, from the tiny plant to the pyramid or standard many feet in height. From these alone it can be seen that the nursery is no juvenile, for many years must have elapsed since the largest plants were propagated. Flowering shrubs are apparently numberless, as are those grown for the beauty of their leafage; while of trees, such as Oaks, Limes, Planes, and others, there are the same immense stocks on hand.

Conifers form one of the most interesting departments in this establishment, and the collection would be very difficult to surpass, so complete is it, and so excellent the specimens it comprises. In all there must be several acres of Thuias, Cupressus, Pinuses, Piceas, Yews, and others. Of these the Golden forms, more particularly of the first and second named, are peculiarly beautiful, and as there are plants of each perfect in all respects, much interest is centred amongst them. In the borders of the principal walk almost all the kinds grown are represented, the bulk being relegated to quarters here and there about the nursery. This facilitates comparisons being made by purchasers and visitors, as it is difficult during the planting season for the various sections to be reached in comfort. Thus selections can be made from those referred to, and the plants lifted from their respective positions wherever they may be. The system has much to commend it, and fortunately finds favour in most large nurseries where trees and shrubs are grown extensively.

Fruit Trees and Vines in Pots.

It would not be possible to have found anything more appropriate with which to bring these notes to a conclusion than the fruit trees and the Vines in pots, for, excellent as are the occupants of the several other divisions, these are no less so. Clean, strong growth is the main characteristic. There is no grossness, no over-luxuriance or sappiness, which warn the experienced cultivator that fruitfulness is scarcely likely to accrue. Quarter after quarter is noticed of Apples, Pears, Plums, Cherries, Peaches, Nectarines, and all kinds of small fruits. Here are standards and pyramids, there bushes, whilst yonder are sections of trained trees all in fine condition. At the time this visit was paid the quarters were even and well stocked, but before another six months have passed they will be thinner and considerably more untidy by reason of the gaps made by those that will be removed. The Vines in pots are a speciality, and more than this need not be said to guarantee the excellence of their condition.

Another word or two and we have done. The references to this visit to Messrs. R. Smith & Co.'s nurseries must not be finished without mention being made of their surprising cleanliness. Acre after acre was observed with scarcely a weed on it, while there was probably not an acre of the whole 200 that was not occupied to its fullest extent. It cannot be questioned that the land and its occupants are most creditable to the firm and to the men employed thereon.—STRANGER.

Maréchal Niel on Gloire de Dijon.

As everyone knows this Rose, and it is so universally admired by all classes, amateurs in possession of a limited amount of glass structure, who have hitherto failed to grow a strong healthy plant for the roof or back wall, might try to advantage the following simple method of culture.

Plant a dwarf Gloire de Dijon in good turfy loam well enriched, and allow a few growths to go up. On these inarch Maréchal Niel, which must be allowed to take the lead when the union is effected, by gently stopping the Gloire. Good plants are soon obtained in this way. The stock then asserts its superior strength, and throws up a strong shoot from the base, which may be inarched also, and turned to good account. I have seen trees worked upon this principle every year adding a new clean growth, and working the old gradually out—covering large spaces, and bearing heavy crops of first-rate blooms.

A few cuttings may be rooted and grown in small pots to make the work of inarching more convenient if the stem is in too awkward a position to draw down a growing branch for union.—R. A. Anderson, *Alnwick.*

Rose Souvenir de la Malmaison.

A recent note on this fine old and really almost perpetual blooming Bourbon Rose reminds me of one I saw growing in a glass corridor recently at Cricket St. Thomas, the late residence of Lord Bridport, near Chard, Somerset. There Mr. Lyon, the gardener, drew my attention to a fine climber which had filled a great portion of the back wall of the corridor with luxuriant growth, and on which were just two or three blooms exactly like those of the well-known dwarf Souvenir de la Malmaison. It is there termed the Climbing Souvenir. Is there really such a Rose in commerce, and if not, what variety is it at Cricket? It is a curious thing that whilst Rose varieties have been during the passing half century so numerous, and so many have been almost reproductions of others, that we have never found any one at all like the old Malmaison. There is a large bed of it at Hampton Court Palace. It has been planted many years, and yet it is in season always in vigour, and almost always in bloom. Its grave defect doubtless is that it is not a show Rose and is almost unclassable. Its great merit is that it is a splendid garden Rose, and yet it is fifty years old at least. There is, too, at Cricket, in the front of this corridor, but kept repressed so that the light is not excluded, not only climbing Niphetos, but also the dwarf variety and W. A. Richardson. These are like huge long bushes. The true old Cloth of Gold flowers profusely on the roof of a Camellia house, and is presumably fifty years old. Its stem, 16 feet long, is at the bottom about 6 inches through.—A. D.

Garden Roses.

Although what is known as the florists' Rose may be the more popular with the public, it cannot be denied that the section styled Garden Roses is gaining much favour with owners of gardens, as well as the numerous visitors to the Rose shows in June and July. What I mean by garden Roses are those kinds that blossom in clusters, single or otherwise, Crimson Rambler, for instance. Where is there a Rose in the first named section that can compare with Turner's wonderful Rambler as a garden ornament? It matters not whether the plant is growing under glass or out of doors, the effect is unsurpassed. Even for cutting with long stalks and big clusters of bloom this Rose is difficult to excel. When allowed to grow at will, singly, and on grass, is there an equal to it in its wonderful flowering capacity? There is yet another point not touched upon in its favour, the period over which the blooms will last in perfect condition without shedding their petals or even losing colour. I have noted the same blossoms good for a fortnight. It seems incredible, but perfectly true, and that is far and away the most pleasant part of it. Take as other examples William Allen Richardson, Felicité Perpetual, the various Moss Roses, not forgetting the single-flowered varieties, or Lord Penzance's charming Briars, and see in them my idea of garden Roses.

I have long considered them grand for either large or small gardens, and purpose in these brief notes detailing a list of what I consider desirable varieties to cultivate, and as the season for Rose planting is near at hand some readers may be induced, perhaps, to take in hand a few of my favourites. Various methods of growing them will occur to planters, but singly on grass is a favourite way of seeing them to the greatest advantage. As hedges to a path, on a bank, trained over arches, or even trailing over dead or living tree stems, are all suitable places to plant and train them.

Growing in masses in beds in the Rose or flower garden is a good method of dealing with the dwarf or bushy growing sorts. The tall and strong in habit require more space than an ordinary bed on grass or gravel affords to do them justice. They seem to need more head room and some support to trail over or lean upon. It does not pay to prune these Roses in the orthodox manner common to the Hybrid Perpetual section, or even Tea scented varieties. The first year, perhaps, after planting they are best cut tolerably hard back to induce basal growth, wherewith a proper foundation for future use is laid. Liberal treatment in the way of good soil, deeply dug and liberally assisted with manure, is essential to the new vigorous growth so desirable, to give a full and lasting crop of bloom.

As with all Roses early planting is a step towards assuring success in the near future, while copious supplies of moisture at the root during dry weather and occasional soakings with liquid manure, will all aid in giving a stimulus to growth that cannot fail to bring their reward. The mulching of Roses during dry weather, in light soils especially, with half-decayed stable manure is not practised enough. Too often the moisture is allowed to evaporate after the trouble to give water has been taken, whereas an inch or so of some mulching material would check this, keep the roots cool, and at the same time assist in stimulating growth.

Just a few notes on pruning this class of Rose and I will pass on to the selection of names. The point is to encourage as much freedom in growth as possible. For instance, plants of Crimson Rambler in the open, making shoots 6 feet long, may be regarded as being entirely satisfactory. The point, then, in pruning these plants is to cut away all weak and useless shoots, making room for those left. Growths of the class indicated will give huge clusters of bloom on stout stalks their whole length, whereas if these 6 feet growths were cut down near to the ground, as in ordinary H.P. pruning, the season's flower crop would be mainly lost. Encourage free growth, and then provide space for it to mature, is the salient point in pruning; you may then rest content upon a glowing crop of blossoms when the proper time arrives.

In the list of varieties that I purpose giving for future guidance I do not intend to follow any alphabetical order or set method of tabulation, but to jot them down as they occur to my mind.

Fellemberg.—This belongs to the China section. The colour is bright crimson, and the variety is effective and deserving of note.

Isabella Sprunt.—The deep canary yellow blooms of this are well known. It is very free flowering, and beautiful in the bud.

Persian Yellow.—An exceedingly deep yellow Briar Rose, with large, full, double, and freely produced flowers.

Commandant Beaurepaire.—Bright rose, striped with purple and violet, is the colour of this. The flower is large and full.

Bardou Job.—Almost single, but with large petals of bright shaded crimson, produced freely and continuously. It is one of the most beautiful and distinct.

Claire Jacquier.—Nankeen yellow is the hue of this charming little Rose. The flowers are produced in clusters. The plant is a strong climber, and excellent for trellises and arches.

Crimson Rambler. — This is now too well known to require description.

Hebe's Lip.—A distinct and beautiful garden Rose, of which the colour is white, with a Picotee edge of purple. It is amost single. T is is often named Reine Blanche, a variety sent out a few years since, and certified as new.

Gustave Regis.—One of the finest of garden Roses. The canary yellow buds, with their deeper centre, are long and pointed.

Madame d'Arblay.—A hybrid Musk Rose, blooming in large clusters. The colour is white, and the plant is hardy and useful for climbing. It is sweetly scented.

Lucida Plena.—This is a pretty buttonhole variety. The colour is rose, with a deeper centre.

Blanche Moreau.—A pure white Moss Rose of excellent quality.

Baronne de Wassenaer.—This also is a Moss. It is very early, double, and showy; colour deep rose.—E. Molyneux.

(To be continued.)

THE ANTIRRHINUM OR SNAPDRAGON.

One would almost conclude that Antirrhinums as a genus were indigenous to Britain. Two species are considered so. For long, narrow, curved or straight borders, few plants with their habit can equal them. Cottagers with little time to spare for gardening, yet wishing to have a showy piece of ground, could not do better than sow Antirrhinum seeds, and enthusiastic amateurs never fail with them. They grow anywhere—on rocky slopes or among boulders with scarcely any soil. They are splendid for walls, and everyone must have observed how they thrive with no more nourishment than that got from between the stones of a crumbling wall or ruin.

At the same time, light rich soil insures their fullest beauty. Sow seeds during the early part of September, either in boxes, pans, pots, or a cold frame, and after germination and some growth, let each seedling stand free from its neighbours, wintering them in a cold frame. Or early in February sow as above, having a 55° temperature to start with, reducing it as growth, season, and the several shiftings advance. Slight protection when required must be afforded, airing whenever safe. The outcome of this should be beauty, slight fragrance, and satisfaction from July till they fade.

Cuttings taken during August or September from favourite varieties should be inserted in a light dry soil with frame and mat protection, and will be useful for spring planting. Like many other hardy plants, notably Foxgloves, they are self-sowers. Given a sheltered spot in light rich soil they spread their seeds, which lie through winter unharmed.

Three distinct classes exist:—Tom Thumb, dwarf and close; Medium, best for general use, about 20 inches high, and Majus, the type, which attains a height of 7 feet. Few flowers give such a fine choice of colour—pure white, grey white, straw, sulphur, primrose, deep canary yellow, darkest mauve, maroon, vermilion, pink, peach lilac, and others. —A Young Scot.

ALLIUM PEDEMONTANUM.

THE plant represented in the annexed woodcut deserves all that can be possibly said in its favour, for it is an alpine bulbous plant of rare merit, and destined to assist largely in the embellishment of our hardy bulb borders all through the earlier part of the season. It is fortunately quite devoid of the disagreeable garlic smell usually characterising Alliums, and which must be tolerated with the showy flowers of the others. For making clumps in the mixed border or the rock garden this bulb is undoubtedly an exceedingly desirable acquisition, as it increases quickly and without becoming in the least troublesome, so compact is its habit of growth. It is also a most useful pot plant, with a considerable advantage over other spring bulbs in the length of time it remains in bloom, and even after being cut the flowers are quite fresh for a long period. It forms tufts of from four to six narrow grass-like leaves, having a very graceful drooping habit, and above the foliage rise in great profusion the charming umbels of drooping dark rosy-pink flowers. It is increased by division or seeds, which ripen plentifully.—M.

HORTICULTURAL SHOWS.

EDINBURGH.—SEPTEMBER 8TH AND 9TH.

THIS magnificent exhibition was held in the Waverley Market on Wednesday and Thursday last, and was one of the finest ever held under the auspices of the Society. The entries, notwithstanding the backward season, were enormous, upwards of 2300 being received, and yet the competition was very keen throughout, especially in the fruit and cut flower classes. It is impossible in the limits of a short report to give a list of all the prizetakers, but the following were the fortunate exhibitors in some of the principal classes.

The Society, to celebrate the Diamond Jubilee of her Majesty's reign, issued a supplementary prize list, offering substantial money prizes and medals for a group of plants, group of cut flowers, a table of fruit, and a table of vegetables respectively. The entries included some of the best English and Scottish growers, and in each case the first prize went over the border to England. It is to be hoped the Council will see their way to retain these classes in future, for the great fault formerly of Edinburgh shows was their stereotyped nature.

JUBILEE CLASSES.

Taking these first, for a group of plants Mr. J. McIntyre, Darlington, was first, winning the Jubilee silver-gilt medal and £20 with a beautiful and graceful arrangement, using a large Kentia in the centre, on a cork stand, Celosias, Dracænas, Orchids, and fine-foliaged plants, making a bright display. Mr. Malcolm McIntyre, gardener to Sir Charles Tennant, Bart., was a close second.

For a table of cut flowers, 15 feet by 5 feet, prizes to the value of £10, £7 7s., and £5 5s. were offered, from which Dahlias were excluded (which many persons thought rather a ridiculous exclusion for a September show). Messrs. Harkness & Sons, Bedale, were placed first with large and brilliant masses of Helianthus, Liliums, Gladioli, Montbretias, a bold, bright table, but lacking the quality of the second prize group of Messrs. Cocker & Sons, who used large mirrors at the back. Mr. J. Forbes, Hawick, took third place. Mr. Campbell, Blantyre, and Mr. Irvine, Jedburgh, were very highly commended. This was a splendid class, all the exhibits being of the first quality. The Jubilee silver medal went with the first prize.

For the best table of fruit, for which the prizes were £21, £12 12s., and £7 7s. were offered, some magnificent tables were in competition, Mr. J. Hunter, gardener to the Earl of Durham, Lambton Castle, winning with splendid examples of Gros Guillaume and Black Alicante Grapes, Victoria Nectarine, Pavie de Pompone Peach, Magnum Bonum Plum, Brown Turkey Figs, Golden Eagle Peach, Hybrid, and Charlotte Rothschild Pines, Washington and Gascoyne Scarlet Apples, Duchess of York Melon, and Pitmaston Duchess Pear. This was a most meritorious table, not a weak dish in the lot. Mr. R. Cairns, gardener to Martin White, Esq., Balruddery, Dundee, was a splendid second, and the veteran, Mr. Kirk, Alloa, third. The large Veitch Memorial medal went with the first, silver and bronze Jubilee medals with the second and third prizes.

For the best table of vegetables there was the same keen competition, Mr. Jas. Gibson, gardener to W. Watts, Esq., Devonhurst, Chiswick, leading with fine examples of Excelsior and Ailsa Craig Onions, Satisfaction Potatoes, Autumn Giant and Mammoth Cauliflowers, Red and White Celery, Student Parsnip, Lyon and International Leeks, Perfection Tomato, Autocrat Pea, and Best of All Bean, the whole forming a handsome exhibit of well-grown and well-staged produce. Mr. R. T. Rae, gardener to Major Scott Kerr, Roxburgh, was second; and Mr. W. Harper, gardener to J. R. S. Richardson, Esq., Perth, third. The medals were the same as in the preceding class.

GENERAL CLASSES.

For a table of plants arranged for effect, Mr. G. Wood, gardener to J. Buchanan, Esq., Oswald Road, Edinburgh, was first, Eulalias, Cocos Weddelliana, and splendid plants of Oncidium recurvum being effectively used. Mr. J. McIntyre, Darlington, was second.

Mr. J. Napier, gardener to P. Neil Frazer, Esq., Murrayfield, had the best four Adiantums, showing a huge specimen of A. digitatum. The same exhibitor was first with four British Ferns, and also with four exotic Ferns, showing splendid specimens in each case.

Fine double Petunias, Cockscombs, Pelargoniums, Begonias, and Fuchsias were exhibited by the local gardeners. Large Palms and Tree Ferns were placed about the Market, which greatly enhanced the beauty of exhibition, but it was difficult to find the prizewinning plants.

Roses were a fine feature of the Show. For twenty-four Teas Messrs. D. & W. Croll, Dundee, led with, amongst others, Bridesmaid, Catherine Mermet, Ernest Metz, Innocente Pirola, and Madame Cochet. Messrs. Adam & Craigmillar, Aberdeen, were second. Messrs. Cocker & Sons, Aberdeen, won with twelve Alfred Colomb, and Messrs. D. & W. Croll for twelve scarlet Roses, showing Captain Hayward; Messrs. Cocker and Sons were second with A. K. Williams. For thirty-six Roses Messrs. D. & W. Croll won; Messrs. Cocker & Sons were second; and Mr. Hugh Dickson, Belfast, third. For eighteen Roses Messrs. D. & W. Croll were again first, Messrs. Cocker second, and Mr. Smith, Stranraer, third.

For thirty spikes of Gladioli Messrs. Harkness, Bedale, were first

FIG. 40.—ALLIUM PEDEMONTANUM.

with fine clean spikes; Mr. Campbell, Gourock, second. Mr. M. Campbell, Blantyre, was first with twenty-four double Dahlias, staging fine solid well-finished blooms—Shottesham Hero, Colonist, J. Cocker, and Penelope were the most notable; Messrs. Harkness & Sons were second. Mr. M. Campbell was also first for eighteen sprays of Cactus Dahlias, Messrs. R. B. Laird & Sons second, and Messrs. Laird & Sinclair, Dundee, third. For eleven spikes of Hollyhocks Mr. Forbes, Hawick, took the first place; Mr. Irvine, Jedburgh, second. Messrs. Laird & Sons had the best eighteen single Dahlias, staging immense sprays; Mr. John Downie second.

Herbaceous flowers were staged in bewildering profusion. For twelve bunches, Mr. Bryson, Innerleithen, was first, showing grand bunches of Montbretias, Lobelia cardinalis, Veronica longifolia subsessilis, Statice incana, and many others; Mr. Meiklem, Bridge of Weir, was second; and Mr. Patterson, Selkirk, third. Mr. M. Campbell, Blantyre, won with twelve Carnations in a great competition.

FRUIT CLASSES.

For a collection of twelve dishes of fruit, Pines and Bananas excluded, Mr. J. Hunter, Lambton Castle, took the lead with fine bunches of Chasselas Napoleon, Gros Guillaume, and Gros Maroc Grapes; Golden Eagle Peach, Victoria Nectarine, Pitmaston Duchess Pear, Gascoyne Scarlet Apple, Magnum Bonum Plum, Moor Park Apricot, Brown Turkey Fig, and Washington Apple. Mr. Harris, gardener to Lady

Henry Somerset, Ledbury, was second; and Mr. J. McHattie, Strathfieldsaye, third.

For eight dishes, Mr. Harris was first with Black Hamburgh, and Muscat of Alexandria Grapes, Barrington Peach, Lady Sudely Apple, Lord Napier Nectarine, and Pitmaston Duchess Pear as the leading dishes; Mr. D. Kidd was second, and Mr. Martin White third.

For six bunches of Grapes, Mr. Lunt, gardener to A. Stirling, Esq., Keir, won with Gros Maroc, Museat of Alexandria, and Black Hamburgh; second, Mr. White; third, Mr. J. Leslie, Pitcullen House. For four bunches, Mr. D. Kidd, gardener to Lord Elphinstone, Musselburgh, was placed first with superb bunches of Muscat of Alexandria, Mrs. Pince, Gros Maroc, and Muscat Hamburgh. Messrs. D. and W. Buchanan, Kippen, were second; and Mr. D. Airdrie, gardener to J. H. A. Graham, Esq., Larbert, third. There were five entries, and either good enough for a first place.

Mr. D. Kidd was also first for two bunches of Muscat of Alexandria; Mr. R. Cairns, Balruddery, was second; and Mr. W. Rutherford, Anthony Castle, third. Mr. J. Matthison, gardener to Messrs. Craig of Currie, was first for two bunches of Black Hamburghs; second, Mr. J. Menzies, Dunipace; third, Mr. Sutherland, gardener to T. Learmouth, Esq., Polmont. For one bunch of black Grapes Mr. J. Day, gardener to Earl of Galloway, Garlieston, was first with Gros Maroc; second, Mr. McLean, Alloa, with Madresfield Court; third, Messrs. Murray & Son, Orchard Park, Polmont, with Gros Maroc. Mr. McLean, Alloa, won for the best bunch of white Grapes with Buckland Sweetwater. Mr. T. Sutherland, Polmont, had the finest flavoured black Grape in Madresfield Court. Mr. D. Murray, gardener to the Marquis of Ailsa, Maybole, had the finest flavoured white in Museat of Alexandria.

Vegetables.

These were very fine. Mr. J. Waldie, Dollar, was placed first for a collection of twelve varieties, showing splendid Leeks, Onions, Celery, and Carrots; Mr. A. Dickson, Glenmoriston, was second; and Mr. W. Harper, Perth, third. Leeks are always a feature of the Edinburgh Show. For twelve Mr. J. Hood, gardener to Miss Baillee, Dryburgh House, St. Boswells, was first with splendid specimens, blanched over 16 inches. Mr. S. Ormiston, Jedburgh, was second. Mr. J. Gibson, Chiswick, won with six Parsnips. Turnips, Cabbages, and other vegetables were exhibited in large quantities.

Trade Exhibits.

Of course in such a large show the trade was well represented, and their exhibits alone would have made a splendid exhibition. Messrs. Dickson & Co., Waterloo Place, had Vines in fruit and other plants; Mr. J. Downie, Prince's Street, stove and greenhouse plants; Messrs. J. Grieve & Sons, foliage plants and cut flowers; Messrs. Methven and Sons, fine-foliaged plants; and Mr. Phillips, Araucaria excelsa. All the above are Edinburgh nurserymen.

Messrs. Bunyard & Co., Maidstone, exhibited fruit; Messrs. Laing and Mather Carnations and single hybrid Chrysanthemums; Mr. Eckford, Wem, his famous Sweet Peas. Messrs. Cocker & Sons, Aberdeen, had a fine collection of herbaceous flowers, arranged in a huge bank; Mr. John Forbes, Hawick, showed herbaceous flowers and Carnations.

Messrs. Dobbie & Co., Rothesay, occupied 250 feet with 300 varieties of Dahlias arranged in sprays, interspersed with Ferns and backed with Palms—a glorious show; Mr. Kerr, Dumfries, also had Dahlias. Mr. A. Lister, Rothesay, exhibited Pansies, Dahlias, and herbaceous flowers. Mr. M. Cuthbertson, Rothesay, staged a table of herbaceous flowers. The show was well managed, and better use made of the vast space at the disposal of the Council than in former years.

WELLINGBOROUGH.—September 11th.

The second exhibition of the Wellingborough and Midland Counties Dahlia Society took place in the Corn Exchange on the 11th inst., and Mr. T. Pendered (the President) and the Committee must be complimented upon the remarkable success. Several of the southern growers and exhibitors of Dahlias came with their flowers, and so numerous were the entries that the capacities of the Corn Exchange were tested to the utmost, and some of the vegetables, which were numerously shown by cottagers and gardeners, had to be accommodated in an ante-room. There is no doubt that an important exhibition of Dahlias can be maintained at Wellingborough, if only the inhabitants will give it a proper measure of support. It is a centre readily reached from all parts, as well as in a district which appears to admirably suit the Dahlia.

Several classes were open to all England. The leading one was for twenty-four blooms, and there were nine entries. Some exhibitors had large, coarse, ungainly blooms, as if size would rule with the Judges above every other consideration, and they can now, no doubt, see how illusory was any such expectation. The stands from Mr. S. Mortimer, Swiss Nursery, Farnham, and Mr. Geo. Humphries, Chippenham, came so close together in point of merit that the Judges awarded them equal first prizes. The former had very fine blooms of John Hickling, J. B. Service, Mr. Gladstone, Shottesham Hero, Glowworm, Arthur Rawlings, Duke of Fife, Walter H. Williams, Frank Pearce, and Lord Chelmsford. Mr. Humphries' leading blooms were John Hickling, Glowworm, Mrs. Langtry, William Rawlings, Miss Cannell, Florence Tranter, James Stephens, Henry Walton, and Miss Fox. Mr. J. T. West, Cornwalls, Brentwood, was second; Mr. J. R. Tranter, Henley-on-Thames, was third. With twelve blooms Mr. Mortimer was placed first, having in fine character J. B. Service, Thomas Goodwin, John Hickling, Duke of Fife, Perfection, Shirley Hibberd, Glowworm, and J. T. West. Mr. West was a good second, and Mr. Tranter third.

Cactus and Decorative Dahlias are shown at Wellingborough on stands in the same way as the Show blooms, and they are decidedly effective, being less formal and uniform in appearance. Mr. Mortimer came in first with twenty-four varieties, having blooms of fine quality, the leading ones being J. E. Frewer, Princess Ena, Gloriosa, William Stredwick, Starfish, Mrs. L. Seymour, Matchless, Delicata, Cycle, Mrs. Gordon Sloane, and the spider-like Fantasy. Mr. J. T. West, who ran Mr. Mortimer very close indeed for first place, had excellent examples of Cæsar, J. E. Frewer, Mrs. G. Sloane, Ruby, Island Queen, Ethel, Octopus, and Beatrice. These two stands proved of great interest to the company, especially as they contained so much novelty. With twelve blooms the same exhibitors were first and second, again staging capital flowers.

For twelve bunches, three blooms of each, Mr. W. Baxter, Woking Village, was first, and furnished an admirable object lesson to the Midlanders in setting up Cactus Dahlias for exhibition. He had in fine character Fusilier, Mrs. L. Seymour, Beatrice, Lady Penzance, Miss A. Jones, and Mrs. F. Fell.

Pompons were shown in twelve bunches, three blooms in each, and Mr. J. Wright, nurseryman, Leicester, was placed first with fresh and bright flowers, rather larger in size than we are accustomed to in the South. Chief among them, Tommy Keith, Darkness, Favourite, Salmon Queen, Little Frank, and George Brinckman. Messrs. Yarde & Co., Northampton, were second. In all the foregoing classes there was a most encouraging competition.

Some open-to-all-England prizes for amateurs were also offered. The best twelve blooms, which were repetitions of those already named, came from Mr. R. Burgin, St. Neots; Mr. F. Middleton, Althorp, was second, and they occupied similar positions with six cut blooms. The best twelve blooms of Cactus came from Mr. H. A. Needs, Horsell, Woking, fine examples of varieties already given and admirably set up. Mr. J. York, Desborough, was second; and they were also first and second with six blooms, and also with six bunches of Pompons, Mr. Needs having nice neat blooms well set up. There were classes also for Dahlias grown by cottagers.

Prizes were also offered for fruit, the best collection of six dishes coming from Mr. Hayes, Castle Ashby Gardens. For Grapes, Apples, Pears, Mr. T. Pendered, the President, taking the first prize in the class for culinary Apples with a fine dish of Peasgood's Nonesuch, Cucumbers and Tomatoes; and there were various classes for vegetables, which were largely exhibited, and generally of good quality.

Certificates of merit were awarded to the following new varieties of Dahlias: Show Dahlia J. R. Tranter, from Mr. J. R. Tranter; Show Dahlia Mr. Pitt, a deep rosy lilac self, from Mr. G. Humphries; Cactus Dahlias Eastern Queen, very dark, and E. J. Deal, bright red, from Mr. S. Mortimer; Cactus Dahlia Mr. Moore, maroon and brilliant crimson, from Mr. J. Green, Dereham; Cactus Dahlia Island Queen, soft mauve-lilac, and Pompon Nellie Broomhead, from Mr. J. T. West.

A very interesting collection of Cactus Dahlias came from Mr. J. Green, and also of Apples from Messrs. H. & E. Lack, Wellingborough, and of Dahlias from Mr. W. Spriggs, the active Secretary of the Society, all of which were highly commended.

THE YOUNG GARDENERS' DOMAIN.

Anthuriums.

These handsome stove plants may be divided into two sections, the ornamental foliaged and the flowering varieties. The former have large, handsome leaves, some being a dark velvety green with silver midribs and veins, while others are a rich glaucous colour. The leaves of several are 3 feet long, and present a bold and striking appearance. It is only in large structures that such plants are seen to advantage, for they require plenty of room to develop their foliage.

The flowering varieties are much smaller, more compact in growth, and although they have not the beautiful foliage of the other section, the deficiency is amply made up by the beauty of their flowers. These vary in colour from white to the darkest shade of red, while some are spotted. They also vary in shape, some having them twisted and bent backwards. For cutting they are invaluable, and when arranged in glasses with Asparagus or Fern the effect is very graceful.

The plants are propagated by division, or if they have become tall sphagnum moss may be placed round the stem, just below the foliage, and if this is kept moist roots will soon be emitted into it, when the tops may then be taken off and potted. The remaining length of stem may be cut off about an inch from the soil into lengths having two eyes to each. Lay these in pans of sphagnum moss and place in a brisk bottom heat; keep moist, and they will soon commence growth. The remainder of the stem on the old plant will also grow if kept moist. Another method of propagation is by seeds, but this is tedious, and requires patience, as it is usually necessary to wait about three years before you are able to find out if your work is rewarded with good varieties.

The material most suitable for potting is two parts fibrous peat, one part loam broken into lumps, one part charcoal, with an addition of sphagnum. The pots must be thoroughly clean, and filled three parts full of crocks. When potting, raise the plants on a cone above the rims of the pots, taking care to work the soil thoroughly amongst the roots. Place them then in a moist atmosphere, where there is a temperature of about 70°, shading from the bright sun and keeping well syringed.

The best of the flowering varieties are A. Andreanum, A. delicatum, A. Louis Fournier, A. albanense, A. Madame E. Pynaert, A. Lady Iveagh, A. Scherzerianum, S. Wardi, and S. Rothschildianum. Among the best of the ornamental section are splendidum, Warocqueanum, Veitchi, and crystallinum.—Elveden.

Indoor Rockwork.

In forming an indoor rockery, the chief object aimed at is to imitate Nature as far as possible, arranging the plants so that rugged pieces of stone are visible, and choosing such as will prove interesting throughout the year. The best stone is common red sandstone, as on this light foliaged plants show themselves to advantage, which is not always the case when planted on white stone.

Many are the modes in which the rockery may be built. Centre beds with a rustic stone base look well, as there is a great advantage in being able to re-arrange the plants on the beds, and having frequent changes. Arches are desirable. A central column is needed to support them, which should span the house, and from which trailing plants, such as Panicum, Tradescantia, Selaginellas, and others should depend gracefully. Where the means are at hand water may be used, and whether in the form of a cascade, fountain, or tank, it gives the rockery an increased charm.

There is a great art in arranging the plants, so that each one shows itself to the best advantage. Plants that retain their beauty for the greatest length of time should be used in preference to short-lived ones. The most suitable plants for the rockery are Ferns and Selaginellas in variety, Rex Begonias, Saxifrages and Mosses, Coleus, and a host of others. Flowering plants may also be used with advantage. The best way with these is, when making the rockery, to leave pockets or crevices large enough to hold the pots, as by this means a constant supply of bloom may be maintained without the continual work of replanting.

The sides and roof of the house should be covered with creepers, gracefully festooned, to meet the plants growing on the rockery. Constant care is needful after planting, in the way of watering and damping, until the plants have got a fair start, and then very little work is necessary to maintain the beauty and freshness of the indoor rockery.—E. J. B.

Clerodendron fallax.

This plant is of immense value for decorative purposes, the splendid bright blooms contrasting well with the deep green foliage, and considering the time it lasts in flower it is a most desirable plant to cultivate. It may easily be raised from seeds or by cuttings, and both methods are good ; but so far as my experience goes the former give the least trouble, as the plants can be destroyed immediately after flowering, as when old they are liable to become harbours for insects.

We usually make three sowings—viz., January, March, and at the end of May, for the latest. The seeds are sown in pans and placed in a bottom heat of about 85°. After germination, and when the seedlings are large enough, they are transferred to 3-inch pots, while for the final shift 6 or 7-inch sizes are the most serviceable. The following soil suits them admirably :—Two parts of loam, one of peat, one of rough leaf soil, with coarse sand added. Firm potting is advisable, and they are placed in a heated pit with a temperature of 60° at night, increasing according to sun heat during the day, and closing early in the afternoon to raise the temperature to 85° or 90°, with abundance of moisture.

When the pots are filled with roots they should be watered three times a week with manure water, and occasionally top-dressed with some approved artificial fertiliser, as the plants are gross feeders. As soon as the flower spike can be perceived, gradually give more air, eventually removing to the greenhouse or conservatory, where they remain an object of beauty for a long time. By saving a few plants annually and cutting back after flowering earlier flowers are obtained. The earliest seedling plants follow these, and a succession of flowers will be produced from about the end of May till December. Care must be taken with the latest, or they will damp considerably, a rather dry intermediate temperature suiting them best to flower in.

The insects most prevalent on Clerodendron fallax, generally, are red spider and aphis. The former is best prevented by growing the plants quickly and well in a warm temperature heavily charged with moisture. Aphis must be destroyed by vapourising or fumigating. It is well known what splendid specimen plants Clerodendron fallax make by pinching the leading shoots and potting as required.—J. L. G.

FRUIT FORCING.

Cucumbers.—The plants for winter fruiting should be placed out as soon as they are ready, a good bottom heat being essential to success. The soil may consist of light turfy loam, with a third of fibrous peat, a sixth of old mortar rubbish and tenth of charcoal, the whole well incorporated. For imparting vigour later rely on surface dressings and liquid manure in preference to mixing manure with the compost.

Plants in Bearing.—Maintain a healthy and vigorous growth by a genial condition of the atmosphere. Avoid closeness by judicious ventilation, regulating the atmospheric moisture according to circumstances, so as not to induce stagnation through excess. Keep the growths fairly thin, going over the plants twice a week for stopping and removing superfluous growth, being careful not to overcrop the plants, cutting the fruit directly it attains the desired size. Be sparing in the use of water over the foliage, but damp the floors and walls in the morning and afternoon, also evening of bright or windy days, gradually however, reducing the moisture as the days shorten and the heat declines. Add a little fresh soil when the roots protrude through the ridges or hillocks, always previously warmed, applying weak tepid liquid manure once or twice a week as may be necessary. Aphides sometimes appear at this time. Fumigate on two or three consecutive evenings, being careful not to give an overdose of either tobacco smoke or nicotine vapour.

Figs.—*Earliest Forced Trees in Pots.*—In April and May dishes of Figs are very acceptable at dessert, and to produce them the trees are best grown in pots. Those not in large pots, say over 13-inch, should have the roots examined, and as it is not advisable to increase the size, a few inches of soil may be removed from the base of the balls. Loosen these a little at the sides to admit of fresh compost, remove the loose surface soil, shorten the roots, and replace in fresh turfy loam with a sixth of old mortar rubbish, and a small handful of bonemeal to a bushel of soil. Afford a good watering, and place the trees where they can have plenty of air with shelter from heavy rains and snow, also safety from frost.

Trees in large pots that are stood on brick pedestals to prevent their sinking require different treatment. In their case every particle of old fermenting material should be removed, also all the surface dressing from amongst the roots, with a hand-fork. After shortening the roots and attending to the drainage, apply a surface dressing of the compost named, and ram it firmly into the pots. Supply water to the soil for settling it, and after this keep the house cool, dry, and well ventilated until the time of starting in November or December. To trees not in as large pots as desired, and those requiring an increase of root space, a moderate shift may be given, the sides of the ball being loosened with a hand-fork, and any straggling roots cut back, those in the drainage being removed. Drain the pots efficiently, employ the soil in a moderately dry condition of the same composition as previously advised, and ram it as hard as the ball.

Succession Houses.—The trees which are ripening second crops of fruit require lessened supplies of water, not affording any until the soil is getting dry, and not then if the moisture is sufficient to keep the foliage from becoming limp, for that condition must be avoided. Withhold water from the house, except a sprinkling occasionally during bright weather, a little fire heat being necessary in dull and wet weather to admit a free circulation of air and prevent damp. Remove all soft and useless wood, thin out where crowded, and when the fruit is gathered cut away the growths that have reached the extremity of the trellis, and are not necessary for next year's bearing. It is absolutely essential that the wood be thoroughly ripened by the exposure of the growths to light and air, and the points of the shoots on which the first crop next year is borne ought to stand well up to the light.

Lifting Unfruitful Trees.—Exuberance and sterility characterise trees in too large and rich borders. Lifting such trees is a certain means, the trees having plenty of light, of inducing fruitfulness, and should be performed as soon as the leaves have commenced to turn yellow. If the trees are very luxuriant it is a good plan to make a trench about half the distance from the stem the branches cover of the trellis, and quite down to the drainage, so as to cut off all roots at the trench. This should be done while the leaves are quite green, fully a month in advance of their turning yellow, and it will check the tendency to late growth, concentrate the energies on the maturation of the wood and buds, almost always changing the character of these, so that they form Fig buds and produce a good crop the following year. Carefully lift the trees when the leaves turn yellow, cut back any strong and long roots, reserving those which are most branched and fibrous. Good drainage is of paramount importance, having a foot thick with a drain to carry off superfluous water ; there is nothing better than brickbats and a thin layer of old mortar rubbish over them. Good turfy loam, preferably rather strong and gravelly, a sixth of old mortar rubbish, and a similar amount of road scrapings form a good compost for Figs, and 2 feet depth is ample. Place the soil firmly in the border to insure a sturdy, short-jointed growth, and spread the roots evenly in the top foot of soil, working it amongst them, and placing them in layers as they rise, not covering the topmost more than 2 or 3 inches. Have the compost moderately dry when used, and afford sufficient water to settle it about their roots. A border of about one-third the width of the trellis—say, 4 to 6 feet—is ample for Figs, and much better than a wide one.

Pines.—*Suckers.*—Those recently started should be raised near the glass as soon as the roots are plentifully made, so as to secure a sturdy thoroughly solidified growth, especially in plants intended to be wintered in small pots. When the suckers become well rooted transfer the strongest started in late summer to the fruiting pots at once, draining these well. Employ the fibrous part only of sound turfy loam, in lumps proportioned to the size of the pots. Jamaicas are apt to become weak and attenuated in growth when grown in large pots ; 9 or 10-inch suffice for them, and they must not be grown away from the glass, or be kept very moist and close. Queens succeed in 10-inch pots, or very strong plants may be given a little more root space, say 11-inch pots ; Envilles have all their requirements as regards soil supplied in 10-inch pots ; Smooth-leaved Cayenne succeed in 10-inch pots, 11-inch at most ; and Providence in 11 or 12-inch pots. The small plants should be shifted into 7 or 8-inch pots, in which they must be kept until spring. Plunge the pots in a bottom heat of 90° to 95°, in which they must be continued until the roots have taken freely to the fresh compost, when they may be raised, a temperature of 85° being afterwards sufficient.

Growing Stock.—Young plants require free ventilation on all favourable occasions to keep them in a healthy sturdy condition, maintaining a night temperature of 60° to 65°, with 5° to 10° more by day artificially unless dull and cold, and keep at 80° to 85° from sun heat. Ventilate early in

the day, but not so as to lower the temperature, keeping the bottom heat steady at 80°. Water the plants whenever they require it, employing weak and tepid liquid manure. Avoid the use of the syringe too frequently, as sprinkling the paths morning and evening will suffice in all but very bright weather. Fruiting plants should have a night temperature of 70°, with 80° to 90° by day, closing at 85°.

Strawberries in Pots.—Watering the plants must not be neglected, but they are seriously injured by continued needless watering. The varieties intended for early forcing should soon be given the protection of frames, only using the lights in frosty weather and to throw off heavy rains and snow, ventilating freely when the weather is mild, withdrawing the lights when fair, and when wet tilting them. Any plants that have the soil very wet, and remain so for some time without watering, should have the drainage seen to. The crowns are often too numerous, not on La Grosse Sucrée, but on Vicomtesse Herieart de Thury. Where a number of crowns cluster round the central one, remove the small ones sideways with a wedge-like piece of wood without injuring the central crown or crowns or the leaves. This will concentrate all the vigour of the plant on the chief crown or crowns, and though there will be fewer trusses of bloom there is no need to fear a deficiency of crop. There is nothing like a loose surface for Strawberries in pots, which prevents the soil leaving the sides of the pots, and admits of the water passing evenly through the ball, moistening the soil thoroughly. A little dried cow manure or horse droppings, rubbed through a quarter-inch sieve, applied to the surface of the pots, will keep all right there. Remove all runners as they appear, also weeds, and do not allow the plants to suffer through want of room, giving them plenty of space for the full exposure of the foliage to light and air, which is essential to a steady growth and plump, well-developed crowns.

THE FLOWER GARDEN.

Bulbous Plants.—Any bulbs in a dry state are considerably weakened by being kept out of the ground much later than this, though as far as bedding Hyacinths, Tulips, Narcissi, and Crocuses are concerned they cannot well be planted before the beds are cleared of their summer occupants. In addition to taking an early opportunity of planting miscellaneous bulbs, newly bought in or otherwise, advantage should also be taken of a dry time in September or the early part of October for lifting, dividing, and replanting many of the bulbous plants already established on the place. Not that these require annual or even biennial attention, but most of them pay well for lifting and replanting every third or fourth autumn.

Anemones.—The apennina, nemorosa, vernalis, and coronaria types are all perfectly hardy. They are very beautiful in the early spring and summer months, and are simply indispensable where bright coloured flowers are largely required for cutting. They succeed admirably in a variety of positions, including fruit borders. They ought to have the benefit of a freely worked loamy soil to which road grit or sand and well decayed cow or horse manure have been freely added. Dispose the roots 2½ inches deep and about 5 inches apart each way.

Crocuses.—Patches of these in variety are very effective near the fronts of shrubberies and mixed borders, where, if they are planted early and about 4 inches deep, they will increase rapidly, paying well for lifting, dividing, and replanting every third or fourth autumn.

Crown Imperials and Fritillarias.—These ought not to be disturbed often, but if there are signs of failure or it is desirable to increase the stock of any of the varieties, directly their growth is completed, lifting, dividing, and replanting may take place. They ought not to be very roughly used, but a small ball of soil and roots should, when possible, be saved with each bulb, the replanting not being long delayed. Mixed borders and the fronts of newly formed shrubberies are the best positions for this class of plants, there being then no necessity for often disturbing them. Any bought in should be obtained and planted not later than October. All require a rather rich loamy soil, those that have been purchased or roughly used being well surrounded with sand. Plant just below the surface in groups of three or six bulbs.

Cyclamens.—Both C. Coum and C. europæum are comparatively hardy in the more southern parts of the country, and are admirably adapted for rockwork. The present is a good time for planting them; they ought to have a rather dry sheltered position and a light sandy soil to root in. Plant in groups of about three plants.

Dog's Tooth Violets.—These are more hardy than the foregoing, and are worthy of cultivation for their beautiful leaves alone. They thrive best in a peaty sandy soil, where, if not interfered with, they spread rapidly. The fronts of shrubberies and the margins of beds are the best places for them. If the soil is of a somewhat heavy nature add common peat and sand freely, or failing the former use abundance of good leaf soil.

Hyacinths.—Those permanently planted should not often be disturbed, but when they are moved, September and October, or before fresh root action commences, will be the best time to do it. Late in October or early in November is quite soon enough to plant new bulbs in beds or borders. The Grape, Feather, and Musk Hyacinths are of a very different character, and all are very effective in their way. Every four or five years is quite often enough to disturb them, and they ought therefore to be planted rather deeply in front of the borders. They are not particular as to the kind of soil they are planted in.

Irises.—About every third season the bulbous-rooted varieties ought to be lifted, divided, and replanted, taking care not to wholly clear the roots of soil. This may well be done now, and new bulbs planted as soon as they can be had. They all ought to have the benefit of a freely worked well-enriched soil, and if planted somewhat thinly, or about 8 inches apart, and fully 4 inches deep in beds, the surface of the latter during the winter and spring may be furnished with Alpine Auriculas, Pansies, and such like; and during the summer with Verbenas, Mignonette, and other tender plants that do not unduly rob the ground of moisture and fertility.

Narcissi and Daffodils.—These rank among the most serviceable and the most popular spring flowering bulbs that can be grown. To be constantly successful with them they must not be disturbed oftener than every third or fourth year. Single bulbs of choice varieties, given good room and not disturbed, soon surround themselves with offsets, all of which flower grandly when comparatively small, always providing they are not prematurely detached from the parent bulb. It will thus be seen that flower beds are not the proper places for any but the cheap Narcissi of the Polyanthus type; but they will do well near the fronts of mixed borders, shrubberies, and even the open spaces between fruit trees. Commoner Daffodils should also be extensively planted along side paths and drives in woods, and the poeticus type of Narcissi thrive admirably on the banks of ponds and lakes. It may not be advisable to dot them promiscuously over lawns and turf generally, but they thrive well and are very effective when grouped in the turf not far from shrubberies and under high spreading trees. In most cases the tops die down before the grass need be mown, and every season the effect will be greatly improved. From 6 inches to 8 inches apart each way is none too much space to allow all the larger varieties in the various sections, the smaller forms being located about 5 inches apart. Plant to a depth of about 5 or 6 inches. They will thrive in almost any kind of soil, but are most at home in a fairly rich free-working loam, sand or road grit being freely added.

Snowdrops.—These must be planted early, and not often disturbed, or otherwise the stock of bulbs will soon dwindle away. Groups of bulbs 2 inches below the turf on lawns, banks, in shady places, and the margins of lakes, shrubberies, and borders where they are seldom or never disturbed, rarely fail to increase rapidly and flower abundantly.

Tulips.—Any that have been long undisturbed in one place may shortly be lifted and replanted, and new bulbs of border varieties ought to be put out not later than the middle of October. Give them some fresh loamy soil and a little sand to each bulb.

THE KITCHEN GARDEN.

Cabbage.—In many districts wet weather, almost without a break, has been experienced ever since the "spring" Cabbage seed was sown, and as a consequence slugs have had matters nearly all their own way. Where hundreds ought now to be almost ready for pricking out, or even planting out, only a few solitary plants are to be seen. It is too late to sow more seed, with a view to having abundance of plants for moving again this autumn; but any raised soon might stand through the winter in the seed beds, and be available for planting out early next spring. The plan of sowing seed where a portion of the plants are to remain and heart-in early next spring is well worthy of a trial. Select good first early varieties, sow the seed on well-prepared ground thinly in shallow drills 15 inches apart. Directly the seedlings show through the ground dust them with soot and lime, repeating as often as necessary, by way of preventive of slug and flea attacks. If all goes on well a capital lot of plants will be available for transplanting next spring, those left a foot apart in the rows hearting-in early.

Celery.—Wet weather has also greatly interfered with the work of moulding up Celery. Advantage should be taken of dry days to push on with this kind of work, especially if the plants are opening out badly. Once the leaves assume their natural horizontal position they cannot be made to enclose the hearts properly, many of them also splitting when tied up. In all cases remove sucker-growth and the smallest leaves, and after the reserved leaves have been gathered well up together surround them with only enough fine soil to keep them upright. It may be found that partially moulded up rows are comparatively dry at the roots. Unless those needing it receive a good soaking of water or liquid manure before more soil is banked against the stalks "bolting" will take place prematurely. Much Celery is annually spoilt owing to neglecting the plants at the roots after earthing has commenced. If slugs or grubs are troublesome dust soot freely about the stalks. This may entail extra cleaning when the Celery has to be prepared for use; but that is better than disfigured stalks. Celery bandaged with strong brown paper prior to moulding-up is the cleanest of all when lifted for use.

Celeriac.—The Turnip-like base of Celeriac ought now to be swelling fast. These should be kept free from sucker growths and weeds, but must not be moulded up yet. When they are earthed over in October this will be done with a view to affording protection from severe frosts, not because any blanching is necessary.

Late Peas.—Hot weather in July and too many wet, dull days since has had the effect of practically spoiling numerous rows of late Peas. Mildew is rampant, and for this there is no remedy other than a change to warm, dry weather. Where the rows are doing comparatively well small birds have to be reckoned with, these emptying the pods before they are fit to gather. In the case of tall-growing varieties it is next to impossible to protect the pods, small birds finding their way through doubled fish nets even. The medium height to dwarf varieties grown entirely without stakes are the least interfered with.

Potatoes.—Lifting and storing should take place as much as possible during dry weather. As the Potatoes are lifted they should be sorted and stored at once. What drying is necessary can take place in the heaps before the tubers are covered heavily. This is the time to select tubers, and not after they have been spoilt by being treated similarly to the ware or cooking tubers. The latter must be stored in the dark, and

premature sprouting cannot well be prevented. Store all the medium-sized tubers intended for planting thinly in a light airy position, protecting from severe frosts only, and they will be very late in starting into growth accordingly. Ashleaf and other early and second early Potatoes wanted for planting purposes will frequently keep better undug than they will in comparatively warm cellars and other dark places, but they must be heavily moulded over, otherwise the uppermost may be spoilt by severe frosts.

Spinach.—Either the seed sown last month failed to germinate satisfactorily or many of the plants were eaten by slugs before they were noticeable. Where the rows are fairly regular blanks may be filled by transplanting from where the plants are too thick, doing this if possible on a dull day, and watering them in. It is somewhat late to sow more seed, but this should be done where extra wide gaps occur, and plants are scarce. Should the autumn be favourable to late growth a few rows of Spinach sown now may be of good service next spring. Thinning should be lightly done at first, and eventually to a distance of 6 inches apart. Weeds will be kept down, and slugs and grubs prevented from doing mischief, and a vigorous growth of plant promoted, by frequently hoeing among the rows and stirring with a pointed stake between the plants. A dusting of soot will also do good.

Turnips.—In some districts dry weather prevented Turnip seed that was sown from germinating, while in other parts of the country heavy rains constantly interfered with gardening operations generally, with the result that Turnips are likely to be scarce next winter. It is useless sowing more seed at this late date. All that can be done is to take good care of what plants there are growing by timely thinning, occasional sooting, and frequent hoeing among them.

PLANT HOUSES.

Fuchsias.—Young plants that are rooted should be placed singly into 3-inch pots, well watered, and arranged on a shelf close to the glass. Keep these plants steadily growing throughout the winter, and then if transferred into 5-inch pots they will flower early and prove useful for decoration. Where plants have not been rooted cuttings may still be inserted, young wood being selected, and as soon as they are rooted pot them singly, and give them a start in heat. When this practice is followed it is necessary to carefully harden the plants before placing them into cool quarters. A temperature that does not fall below 45° will keep them moving during the winter.

Solanums.—Plants that have set good crops of berrics and have been kept in pots should be supplied with stimulants. Soot water in a clear state is most beneficial for these plants; it acts quickly, and prevents the foliage turning a sickly yellow. Careful watering and feeding are necessary after the pots are filled with roots, or the foliage is liable to turn yellow and spoil the appearance of the plants. Those that were planted out and have set well may be lifted and placed into suitable pots. Where there is abundance of frame room and the Solanums were planted out the plants have a beautiful crop of berrics; but outside plants in many localities are not satisfactory. After the plants are lifted and potted in loam and one seventh of manure, place them in a northern position and give a good soaking with water. Syringe frequently until they commence root activity, when they may be placed in a sunny position.

Bouvardias.—Lift all plants from outside that are making robust growth, and place them into 6 and 7-inch pots, according to their size. Establish them on the principle advised for Solanums. When they will bear exposure to the sun arrange them in frames or in a cool greenhouse where they can enjoy full sunshine. Plants lifted at once will, if the present month proves fine, have every chance of ripening their wood and flowering profusely. Bouvardias in pots under glass must not have their shoots pinched again, but allow them to extend and form trusses. If staking is needed supply a central stake, and support the other shoots with matting. The trusses are not heavy, and thin pieces of matting will support them equally as well as using more than one stake. Feed plants in this condition with weak stimulants every time they need water. Yellow thrips are troublesome, but can be kept under by a free use of the syringe. Fumigation may be resorted to if syringing does not at once check their ravages.

Mignonette.—Plants grown for standards should have the flower trusses removed as they appear, and the shoots tied to the trellis once a fortnight. Keep the plants perfectly cool, so that strong growth will be made until the trellis has been covered, when they may be allowed to come into flower. Later plants required only for spring flowering should be supplied with their trellis, and given the same treatment. Let the whole of these plants stand on a moisture-holding base, and during bright weather syringe twice daily. Plants for pyramids can be tied to the wires or string as they extend. Care is needed to furnish the base first. Water carefully, do not give too much; on the other hand, do not allow them to become dry. Once they are allowed to approach dryness the plants become woody, and they seldom do well afterwards. Mignonette from seed sown in 6-inch pots and kept in frames until germination should be liberally thinned. Failure frequently results from allowing too many seedlings to grow together in the same pot. About half a dozen are sufficient. Sow more seed thinly for spring flowering. Place the pots in a frame, and shade until the seed has germinated, when the plants enjoy full light and abundance of air.

Calceolarias.—The earliest seedlings are large enough for small pots, place them singly into 2-inch, and grow them in cold frames. Those of a smaller size should be pricked out singly into pots or pans, 1 inch apart, so that by the time they fill the space they will be ready for potting singly. Shade from the sun, and keep moist.

THE BEE-KEEPER.

Packing Comb Honey.

Great care is necessary in packing comb honey, and although it is not in nearly such great request as it was a few years ago, there is always a market for well finished sections. It is, however, very disappointing to the bee-keeper, after having obtained sections well sealed and perfect in colour, to have them ruined through bad packing. Many dealers have given up stocking comb honey owing to the difficulty they have in keeping it in good condition. If it is delivered to them perfectly free from drip, which is often caused from imperfect packing, there is no reason why it should not keep in good condition for months, or even years.

In the first place, they must not be removed from the hive until they are well sealed over. Afterwards each section should be examined, and the propolis that adheres to the wood removed with a blunt knife. If any stains remain they may easily be removed by using a little coarse sand paper, and will then be as clean as when first used. This is a great advantage in offering them for sale, as they have a much more pleasing appearance.

Each section on its removal from the crate should be marked with a pencil to denote the top, as they must always be stood in the same position they occupied in the hive. This is important, as it is well known to the majority of bee-keepers that the bees always build their cells with an upward slope, so that each may be filled to its utmost capacity without overflowing, but reverse the comb and part of the honey will at once run out. This shows the care that is required in packing, either for short or long journeys. Also if not packed firmly, even when placed in the right position, it is easily damaged.

Size of Boxes for Packing.

I prefer boxes that will hold about two dozen 1 lb. sections; a few more or less is immaterial so long as the package is not too heavy. It is not necessary to have specially made boxes for the purpose, as grocers' empties, such as margarine boxes, are of a useful size, and answer the purpose admirably. First line the box with clean paper, and then place the sections closely together in rows in a single layer until the box is full. There will probably be an open space at the end in which there is not sufficient space to insert more sections; a piece of cardboard should then be placed over the face of the sections and turned over a few inches on the top. The space between the cardboard and the box should be filled with soft paper, also any space that remains between the ends of the sections and the sides of the box. This must be pressed in firmly, so that it is not possible for the sections to move even if they have rough treatment. The intervening space between the tops of the sections and the lid may be packed in the same manner, for which purpose several layers of newspapers are suitable. Small packages with firm packing is the secret of comb honey being sent long distances by road, rail, or water without injury.

Another Method of Packing.

Another safe method of packing comb honey is to place half a dozen 1 lb. sections together; at each end place a piece of thin wood slightly larger than the section, pass a piece of thin string tightly round the whole, and this will keep them in position. Wrap each parcel of six in paper and fasten firmly with string, care being taken that the sections are placed in the same position they occupied in the hive. It is, of course, advisable to place a prominent mark on the outside of each parcel to denote the top of the sections. This will prevent them leaking, which they will do if placed in any other position.

I lately had a practical illustration of the necessity of carrying out these instructions. Calling on a tradesman who deals largely in both run and comb honey, he showed me some packages of comb honey packed in parcels, as above. To all outward appearance they had travelled well, but on examination it was found they had been placed indiscriminately, and several of them were leaking badly, at least 25 per cent. being taken off their value. Had they been packed in the manner advised, and the tradesman duly advised of the fact, they would doubtless have been delivered in good condition. It is the small matters that make all the difference between good and bad packing.

In whatever form honey is packed, it is advisable to mark each package "Fragile, this side up, with care." By taking these precautions comb honey may be sent from one end of the kingdom to the other. Larger packages may be used, and two or three layers of these parcels can be packed in each box, but when this is done it is advisable to place a layer of hay at the bottom of the box and between each parcel of sections, when it is surprising the amount of rough usage the boxes will stand. It is not necessary to send large

packages by passenger train, as I have proved on several occasions they are carefully handled, and delivered in reasonable time when forwarded by a cheap rate per goods train.—An English Bee-keeper.

[Our correspondent, "R. I.," has sent us sections of honey, but omitted his changed address.—Ed.]

TRADE CATALOGUES RECEIVED.

Barr & Son, King Street, Covent Garden.—*Bulbs.*

C. Phillips, Bracknell, Berks.—*Carnations and Picotees.*

TO CORRESPONDENTS

*** All correspondence relating to editorial matters should, until further notice, be directed to "The Editor," 8, *Rose Hill Road, Wandsworth, London, S.W.*, and *not* to Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Boards for Chrysanthemums (*J. C. B.*).—The size of boards for twelve Japanese Chrysanthemums, as fixed by the National Chrysanthemum Society in 1895, is 28 inches by 21 inches, 3½ inches high in front, and 7 inches in height at the back, the holes to be 7 inches apart from centre to centre.

Hollyhocks and Watsonia Ardernei (*W. Davies*).—The samples of seedling Hollyhocks are very good, but a strain cannot be fully represented by one selected variety. We cannot say that the blooms are equal to the best named varieties which we have seen exhibited. This would be more than could be reasonably expected. We wonder why you did not send several blooms of dissimilar varieties instead of three or four spikes of one variety. Your practice of sowing early in June, establishing the plants in 6-inch pots, and plunging these in ashes in a cold frame for the winter, we know from experience is good. The spikes of Watsonia are charming, but you do not indicate your method of growing the plants.

Artificial Manure for Vine Border (*T. C.*).—Of the three mixtures you name we should prefer No. 2—namely, three parts steamed bonemeal, two parts sulphate of potash, and one part ground gypsum; but instead of "steamed" we should simply use "bonemeal," as there is more nitrogen in it, and no loss takes place by the escape of the ammonia, as the soil holds it until spring, when, by conversion into nitrate, it can be appropriated by active roots, otherwise it passes off in the drainage water. The appreciable loss by volatilisation is scarcely worth mention in winter. Thus you would secure some available phosphoric acid, nitrogen, potash, and lime, with the energising sulphur, by the time the Vines put forth leaves and roots: then, if supplemented by the spring dressing, namely, three parts dissolved bones, 1½ part nitrate of potash, 1½ part sulphate of lime, and half-part sulphate of magnesia, the crop could not be otherwise than well nourished, and the Vines in good condition for another season. No. 3, however, has much to recommend it in case the border is somewhat sour by the use of stable or farmyard manure in solid or liquid form, but instead of gypsum we should use best chalk lime, air-slaked, three-quarters of a pound per square yard, and then follow with three parts dissolved raw bones and two parts sulphate of potash, first pointing the lime into the border, and using the "artificial" with the top-dressing of loam. You will get sulphate of lime in the dissolved bones, and the lime being down will not cause much, if any, loss of ammonia. It is not advisable to use kainit, except in making borders, as unless the border be outside the chlorine is not washed out, and the effect may be seen in the yellow colour of the foliage in spring, otherwise it acts well in the proportions you name—three parts bonemeal and two parts best quality kainit. If you use this, the border being outside, we should modify the spring dressing to three parts dissolved bones, two parts nitrate of potash, and one part sulphate of lime. In the kainit you will get magnesia, so there is no need to apply it again in the spring.

Diseased Carnations (*C. A.*).—The specimens shall be carefully examined. We have heard of syringing with limewash, allowing it to dry and remain on the foliage for most of a week, acting beneficially. Bordeaux mixture may be expected to be more potent. It has been found, by carefully conducted experiments in America, that a more dilute mixture than is usually advised answers equally well. The original mixture is therefore abandoned, and the following employed:—Copper sulphate 6 lbs., quicklime 4 lbs., water 45 gallons. Mix the bluestone and lime in separate vessels, the former in hot water, then place together, stirring thoroughly. Adding 1 lb. of softsoap in solution is said to be advantageous. The mixture should be applied with a sprayer, to rest on the leaves like dew, not running off them like rain after a heavy shower.

Kitchen and Flower Gardening (*Inquirer*).—The cheapest book we know which treats practically on flowers, fruit, and vegetables is the "Garden Manual," post free 1s. 9d., from the publisher, 171, Fleet Street. There are several designs on planting flower beds in the "Parks and Gardens of London," post free for, we think, 2s. 11d., from the same address. It is impossible to teach the use of tools on paper. If young men cannot learn their use in gardens they cannot rank as gardeners. The only safe way that we know in acquiring a business is to inquire for one for sale, examine the books carefully, and thus ascertain its value, on which the price can be determined. In some towns there may be room for starting a new business, but this, considering your unfortunate ill-health, would be too risky for you to undertake. You should have sent your name and address. If you want a higher class book on vegetables you had better enclose a stamped directed envelope.

Pinus halepensis (*Somerset*).—This, the Aleppo Pine, was introduced into this country by Bishop Compton in 1663. It is of rather spreading habit, and often has a thin appearance, as the leaves are not so persistent as many other species. It is said in Veitch's "Manual of the Coniferæ," an excellent work, to "thrive amongst the rocks of the Mediterranean shore, where comparatively few other trees find subsistence. The stems and branches often assume the most fantastic contortions, from the direction given to the south-west wind by the rocky angles exposed to it. In England it requires a sheltered situation." Your young trees will not be ready for planting for some time. They might, perhaps, succeed in the position you name, especially if some robust growing trees, such as Austrian Pines were planted for shelter now, though the probability is that the Aleppos would have a more or less stunted or "fantastic" appearance as they slowly advanced in growth.

Winter Dressing Vines and Fruit Trees (*J. Guy*):—The simple formula for preparing the mixture to which you refer as having been used successfully by Mr. S. T. Wright for dressing Vines and fruit trees at Glewston Court was taken by him from the *Journal of Horticulture*, page 513, June 27th, 1889. Mr. Leonard Coates there wrote from Napa, California:—"It is customary to spray our orchards thoroughly in the winter with a strong caustic solution made as follows:—½ lb. of caustic soda (Greenbank's 98° per cent.), ½ lb. of crude commercial potash (pearlash), dissolved in 5 gallons of water for Pears, Apples, and Plums, in 8 gallons of water for Peaches and Apricots, to be applied at a temperature of 130°. This wash will kill the eggs of almost any insect, and leaves the bark in a smooth, healthy condition." We have seen striking examples of the efficacy of this dressing in orchards, and at least one of its safety as applied to Vines. Finding last spring some young "red spider" emerging from under the bark of some Vines at Chiswick, Mr. Wright on raising the bark found colonies of eggs. Though the Vines were breaking to the extent of a quarter of an inch or more he at once dressed them with the solution, presumably the weaker form for safety. It destroyed every egg and emerging mite without doing the smallest damage to the Vines. By this prompt action all invasion of "red spider" was prevented. The Vines remained clean throughout the season, and are now ripening excellent fruit.

Analysis of Kitchen Garden Soil (*Ignoramus*).—We do not, as a rule, advise analysing soil. The analysis has often no practical value, for though showing the characteristics of the soil, there is nothing to show what parts of its constituents are available as food for plants, and what unavailable. For practical purposes we prefer to find the requirements of the different crops on a given soil by the effects or non-effects of manures. Analyses, interesting as they are from a scientific point of view, are of comparatively little value to the practical cultivator, and most intelligent workers get on much better without than with the tantalising elaborations of the laboratory. The analysis of a soil has to many a cultivator been money thrown away, for either he knows or does not the nature of the land, and unless he knows, the result of applying scientific methods without knowledge of their practical working, he will be disappointed. Most County Councils have an analyst, who for a fixed fee undertakes to analyse soil and crops. If you really desire to indulge in the luxury of an analysis of your soil by all means do so, and if your County Council cannot aid you, we will send the address of one or two competent gentlemen if you send a stamped directed envelope for the purpose. From them you can ascertain the cost of the work, and they would also naturally inform you of suitable manures to use, as we could if we knew the nature of the soil; but as to providing separate mixtures to all the different crops, we have never found it necessary to go to such trouble and expense. If you wish to experiment in that direction, send 7d. in stamps to Mr. W. Dyke, St. Margaret's, Ware, for his pamphlet and leaflet, and you will find plenty of good formulæ to begin with. This will be less costly than an analysis, though, of course, you can have this as well if you so desire.

Niphetos and Marechal Niel Rose Buds Browned (*Nuarb*).—The browning appears due to moisture resting on the petals, which destroys the tissues and can only be obviated by an early and free admission of air, including some at night, and thus prevent moisture from being condensed on the flowers. If there be a heating apparatus in the greenhouse the slightest warmth in the pipes would be sufficient to keep the air in motion and save the flowers; at least, we have found it so in a similar case. They damped in an unheated house, and in one with a very little warmth in the pipes and the ventilators partially open at night they were simply superb. We also found that some superphosphate made a wonderful differenee in the flowers expanding, and in their size and tint. The merest sprinkling occasionally of the following mixture acted well. Three parts dissolved bones, dry and crumbly; two parts nitrate of potash, finely powdered; and one part sulphate of lime, mixed thoroughly, used about every three weeks during growth, and washed in. This and cutting away all the weak growths gave stronger, which trained thinly gave excellent results. Owing to the letter being sent to the wrong address it was just too late for answering last week.

Preventing Club in Cabbage Plants (*D. P.*).—It is difficult to prevent club-root in Cabbage plants when so little time can be allowed between dressing the land and putting out the plants, as must be the case with spring Cabbage. Foul land requires drastic treatment, such as a dressing of gas lime, 5 tons per acre, leaving it on the ground for at least six weeks before ploughing in. Now it will only be safe to apply half that amount, and even then it should lie on the surface three weeks before being turned under, but we have used it and planted a fortnight afterwards with good results. The following dressing also answered well—Peruvian guano (8 to 9 per cent. ammonia), 2½ cwt.; mixed with 2 cwt. of salt per acre, applying just before putting out plants. What the land wants is lime, and in bad cases 10 tons per acre is nccessary, but 5 or 6 tons usually prove effective. As an alternative use 3 cwt. of steamed bonemeal per acre, and early in spring, or when the plants get well hold of the soil, top-dress with 3 cwt. of salt and 2 cwt. nitrate of soda per acre. The salt forms muriate of lime with that substance, and combines with ammonia, passing into nitrate of lime.

Names of Fruits.—*Notice.*—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. *In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing.* The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. *They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state.* (*W. P. C.*).—1, Tower of Glamis; 2, Beauty of Kent; 3, Beauty of Hants; 4, Hollandbury. (*G. N.*).—1, Winter Hawthornden; 2, Mère de Ménage; 3, Dutch Mignonne. (*J. B. D.*).—1, Autumn Bergamot; 2, Duchesse d'Angoulême; 3, Fondante d'Automne; 4, Williams' Bon Chrêtien; 5, Summer Thorn; 6, perfectly hard. (*H. C. G.*).—1, Loddington Seedling; 2, Court Pendû Plat; 3, Cox's Pomona; 4, Cellini; 5, Sturmer Pippin; 6, Northern Greening. (*R. D.*).—1, Ribston Pippin; 2, Warner's King; 3, Cox's Orange Pippin; 4, Irish Peach. (*C. F. G.*).—As we have repeatedly stated, it is quite useless sending Pears to us for naming which are perfectly hard. Please read the directions printed above and send again. (*A. A*).—Your Grapes reached us practically as a mass of pulp, and certain identification is an impossibility; 1, possibly Black Alicante; 2, may be the same; 3 and 4 suggest bad and good examples of Gros Colman. Your best course would be to visit an establishment where Grapes are largely grown, and find yours by comparison.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*Ignoramus*).—Lycium barbarum, introdueed from Barbary in 1696. It is one of the Box Thorns, and belongs to the natural order Solanaceæ. Its recognised popular name is the Tea Tree. (*D. F.*).—1, Ceanothus azureus; 2, Helenium pumilum; 3, Funkia grandiflora; 4, Colutea arborescens. (*V. W.*).—1, Odontoglossum crispum; 2, dead; 3, specimen insufficient. (*O. B.*).—1, Humea elegans; 2, Oxalis floribunda; 3, Geonoma gracilis; 4, Cocos Weddelliana.

SIDE BY SIDE.

The old copybook maxim was "Comparisons are odious.' Yes, so they may be; but for all that, at times they are necessary. Eaeh man and woman individually thinks that his own burden is the heaviest of all the burdens borne by mankind, and exeept in moments of great despondeney each one eonsiders he bears his burden better and is more patient than his neighbours. But we are apt to undervalue the fortitude of others, more through ignoranee than through any laek of good feeling. We eannot enter into all the little details of their ease, and we see the bright features with such a clear eye.

Our attention has been drawn lately to the price of American agricultural produee—that is, of the American States. We have before us a price list, if we may so eall it, of the vendable artieles in the hands of the farmers. We are asked to eompare these prices with our own prices; and then the question arises, Which of the two nations is in the better plight?

Well, if we eome to take the price list alone as our guide, undoubtedly we are getting more money for our goods, even bad as prices are here; but this is by no means all the question. We are asked to adjudieate on very insufficient data; in faet, we are asked to take a leap in the dark. An English farmer, were he required to make a balance-sheet that could be fairly understood by the multitude,

would have a very difficult task before him. We are not told one word as to the cost of production, and we always imagined that the cost of production formed the basis for a true valuation. Of course, there are such things as fancy prices; but these are just now beside the question.

An Englishman sets down first his rent, and greater than his rent, his labour bill, then rates and taxes, which are many and heavy, especially if he should happen to farm within the boundaries of an urban district. We know several cases of this sort where the tenant helps to pay for, but does not participate in, the luxuries supplied to his town brethren. The highway rates are always heavy —of late years this burden has increased—then come sanitary rates, school rates, excessive poor rates, and in many parishes certain special rates for the maintenance of dykes and strengthening of river banks. All this takes a great deal of capital, and these calls, instead of being stationary, are always growing. Then every year a large amount must be spent on artificial foods of various sorts, if we would keep our stock in health and up to the mark.

The bill for tillages, perhaps, is not exorbitant, for we buy carefully, and on analysis only, but the bill is there and has to be met. Then come all the minor expenses, tradesmen's bills, the blacksmith, the ironmonger or implement maker, the wheelwright, the farrier, and a hundred other oddments that together make a very substantial total. Then a certain sum a year must be written off for wear and tear of dead stock, and no farmer gets through a twelvemonth without several funerals, and usually the least valuable are spared.

All these items have to be taken into consideration before the price of one single commodity can be adequately fixed. We have a long time been doubtful as to the advantages of owning land. A tenant farmer gets pulled up by his landlord before he has time to become absolutely penniless. An owner goes on from bad to worse, with no remission of rent to help a bad season—he probably over-estimates the value of his land, and only awakes to the true state of affairs when he finds himself a hopeless bankrupt.

Our American friend says "three parts of our business is done on credit, the remainder on borrowed capital." He gives us no idea of the class of land farmed, no idea of rent, no idea of taxes, except that he states they are increasing. The class of farmer of whom he speaks seems to be on a par with our 50 and 100 acre men, for he says most of them do a great deal of their own work. Were the holdings larger, that would be an impossibility. He gives no wage table, no railway rate; but from his figures, living must be very cheap. He says the average Wheat crop is 13 bushels per acre. Well, all we can say is, either the land is very poor or shockingly farmed. Such returns would break the Bank of England. He does not tell us the quantity of Maize per acre, although he speaks of the price as 11d. to 1s. per bushel. These 13 bushels of Wheat per acre make 39s., and we have made less than that here, but we do not go on sowing such a poor paying crop. He speaks of Strawberries rotting on the plants. Why plant them so far from a market? "Good horses from £10 to £15." Well, that word *good* is open to much question, except where English sires have been used. The American horse does not amount to much. "Beef 2½d. per lb. (dressed), mutton 2½d. lb., hog (pig) 2d. lb." We do not know the beef and mutton, but we do know the hog is dear at 2d.

"Many of the farmers are paying interest from 6 to 8 per cent." Well, they either do not offer very good security, or America must be an El Dorado for investors. We cannot find a safe investment here paying more than 5 per cent. Certainly the Americans can teach us one good lesson, and that is how to make machinery light as well as strong. They have a pull there, and we owe them a great debt for handy useful implements, easy to work and good to keep in repair. But we may have too much even of machinery, as many English farmers have found to their cost this autumn. As all the corn crops were fairly even and level, with no laid places or twisted or storm-broken patches, a great breadth has to be cut and tied by machinery. All went merry as a wedding bell till the weather broke. The farmer had been congratulating himself on the saving in his labour bill; but when a press of work came, when the bright harvesting days were few, where were the men? No machinery can fork into waggons, no machinery can stack, and the short-handed farmer found himself involved in a fearful difficulty.

In this uncertain climate it will always be a case of men and machinery—men first. To put the matter shortly, the American farmer has only himself to thank for the ruin which stares him in the face. The majority of them started with little or no capital, save the capital locked-up in a virgin soil. That soil they have cropped and cross-cropped, in defiance of every known rule of agriculture, and now they find the land no longer yields her increase.

It is only by careful rotation of crops, by constant manuring and first-rate tilling that land for Wheat growing can be kept in heart. We have learned our lesson this side of the Atlantic, and our brethren are learning their lesson now. By-and-by the world will need all the corn land there is, and will demand that such land be treated so as to yield the highest possible returns, and then there will be a chance (and not till then) of corn growers being owners of a remunerative crop. Here, in the old country, it is considered absolutely necessary, or was a few years ago, to have capital at the rate of £10 per acre. Have our American friends as a body ever had 10s.? We fancy not.

WORK ON THE HOME FARM.

Thatching has been almost completed during the past week, but the weather has been so bad that the Barley rakings are still in the fields, and likely to remain there unless we have a change. They are seriously damaged, but having all the sheaves safely stacked we must not grumble, but be thankful we have done so well. We hear very bad reports of damage done to grain still outstanding, and find the damage much more widespread than we had expected. Having measured others' good fortune by our own, we are sorry to discover the mistake, and trust that a spell of fine weather now may do much to minimise disaster.

We have run the cultivator through the stubbles, but the weather has been much too wet to do anything else there, but ley is now ploughing well, so there is plenty of work for the horses.

Two days' threshing have given us a fair idea of what harvest results are likely to be. Wheat, as we have stated before, is a fair yield, and the quality is good. Barley thrashes smaller even than was anticipated, and the portion of tail corn is large. Colour is very good, but we suppose the maltster will want size this year; he always asks for that which the farmer has not got to offer.

Midseason Potatoes are being marketed. They are a light crop, and though meeting a better demand than usual at this season they are not making much per acre. The late kinds are making second growth, and are, in fact, almost in full flower. This will mean a much increased crop, but deterioration in quality and a late Potato harvest, which is invariably an expensive one.

Ewes have now been running with the ram some time where early lambs are wished for, and farmers are generally putting them together. Hedges about home, if not trimmed before harvest, should be attended to now before the extra hands are paid off; there is always plenty of work for the regular men during the winter at scotching and plashing.

This is a good time to paint or tar gates and fences.

REMARKS.

5th.—Rain early hours up to noon, and again from 6.30 to 7.30 P.M.; dull, damp, and cold all day.

6th.—Morning fair, and afternoon bright.

7th – Bright early and up to noon; cloudy till 4 P.M., and sunny after.

8th.—Overcast early; generally sunny morning; overcast from about noon, and rain at night.

9th.—Rain early; dull till 10.30 A.M.; afterwards alternate sun and cloud; bright at night.

10th.—Bright and sunny all day, fine night.

11th.—Fine morning; dull about noon; fair afternoon, and fine night.

Much finer than the previous weeks, and also cooler.—G. J. SYMONS.

PRIZE GRAPES.
(FROM YOUTHFUL VINES).

WINNING the first prize for Muscat Grapes at a Shrewsbury Show is quite sufficient evidence of the excellence of the produce thus honoured. Mr. W. Neild, Horticultural Instructor at the Cheshire Agricultural and Horticultural School at Holmes Chapel, was the most successful exhibitor of two bunches of Muscats at the last great Show; and not only so, but the Grapes were cut from Vines that were raised from eyes last year, and within eighteen months from the time those eyes were inserted. Believing such results worthy of approbation, and the means by which they were attained of publication, we have obtained the following particulars from Mr. Neild, and we thank him for supplying them. He writes:—

"The Vines that produced the first prize Muscat Grapes at Shrewsbury this year were raised from eyes or buds inserted early in March, 1896. The method adopted was to place each bud separately in a small piece of fibrous loam. For the purpose of inducing the formation of roots the buds with their cubes of soil were placed on a thin board resting on the hot-water pipes in the house in which the Vines were subsequently planted.

"As soon as the roots had penetrated to the outside of the soil, and the shoot or stem had grown 3 or 4 inches in length, the young Vines were transferred separately to boxes 12 inches square and 3 inches deep. When the stems were about 2 feet long, and before the roots became matted together, the Vines were planted in the permanent border, and shaded for a few days to prevent the possibility of injury by strong sunshine.

"The border is being formed in sections; at present it is 3 feet in width, 2 feet of this inside the house and 1 foot outside; the front of the house is built on arches, to permit of the roots passing outside. Last year the Vines made strong sound growth, reaching beyond the top of the rafters before the end of the season.

"In the winter they were pruned to within 3 feet of the border, and they are now $2\frac{3}{4}$ inches in circumference at 1 foot above the soil. In spring the buds burst freely and regularly, several of the laterals showing five bunches on each, but were

reduced to one. The bunches exhibited weighed 4½ lbs. and 4¼ lbs. respectively.

"Reverting to the border, its depth is 2 feet 3 inches, or 1 foot 9 inches of soil and 6 inches of drainage. The composition of the border is as follows:– To every six cartloads of soil was added one of old lime rubble, two barrowloads of charcoal and wood ashes, and 2 cwt. of raw half-inch bones. Beyond this no manure of any description was added. The soil, which was taken from the surface of a pasture field, was of a heavy and retentive description. It was not rich in nitrogenous food, which was practically limited to the roots of the various grasses and other plants growing in it. It was also deficient in lime.

"The soil was chopped up roughly, and the other materials thoroughly mixed with it before making the border. When the compost was in a moderately dry condition it was firmly packed together, so that but little settling has taken place.

"During the summer of 1896 a comparatively small quantity of water was applied to the border. A larger supply has been given this year, but still much less than is frequently advocated by some cultivators. It has been asserted that if a Vine border is well drained it cannot be 'over watered.' My belief is that quite as many Vines are ruined by the application of an excess of water to their roots as by using it too sparingly. Some soils have a much greater capacity for holding moisture than others, and consequently they do not require to be watered so often; but whatever the character of the soil may be, whenever water is needed it should be given in sufficient quantity to thoroughly moisten the entire mass.

"The good condition of the soil and the requisite food constituents are essential to the growing Vine, but I believe that the atmospherical conditions to which Vines are subjected are of at least equal importance. Grapes of good quality can be grown when the borders are in an indifferent state, provided the atmosphere of the house is in the most favourable condition for Vine growth.

"The bottom of the border was concreted to prevent the descent of the roots into the clay subsoil. A thorough watering with weak liquid manure was given before the Vines came into flower, and again after the stoning period of the fruit was passed."

Such is the plain practical narrative of the preparation and precedure adopted by Mr. Neild, who is to be congratulated on the success he has achieved so soon at the greatest show of Grapes in England. He is evidently not a believer in "big" borders, nor are we, and he also knows that the best of borders fail in producing superior Grapes in the absence of otherwise good cultural treatment. We rather think we have somewhat of a sensation in store in the way of Vine borders, and hope to show the smallest on record in proportion to the crop of Grapes it has been made to support.

THE OLD GARDEN—A MEMORY.

THERE is a constant, nameless grace
About the dear old-fashioned place
I never can forget.
I find it in the Hollyhocks,
And in the scented rows of Phlox,
The beds of Asters, fragrant Stocks,
And darling Mignonette.

The dear old flowers our grand-dams knew,
The dear old shrubs they loved and grew,
Still make it sweet and fair.
The modern grower, who insists
On novelties from seedsmen's lists,
With barbarous names by botanists,
Will find small pleasure there.

The above tuneful lines by "M. S." in the "Westminster Gazette" come opportunely, one ventures to think, and if savouring of a sentiment which praises the past to the depreciation of the present, one cannot but admit the soothing and softening influence they possess; and few probably will deny the value of these little asides which retouch the notes of some long-forgotten harmony of early life, whose faint reverberations are all but drowned in the din and rattle of latter days.

If the pleasures of gardening are enjoyed as much by anticipation as they are in realisation, like so many of the pleasures of life, retrospection possibly affords the most unqualified satisfaction, hence "A Traveller" tells his little tale of woe, and "Invicta" pines for the open-air Peaches of his boyhood days, softly impeaching those who neglect their walls, and ever and anon some old showman resting on his laurels figuratively shoulders his crutch and shows how fields were won in the brave old days of long ago.

Now, in low-toned cadence "M. S." touches one tender spot that all must have in their hearts, conceal it as they may, for the old-fashioned garden — the garden of auld lang syne. Fewer and farther between as we hurry along are these havens of all that is restful, such an one as above depicted; for somehow this restless spirit of the age appears to have invaded most gardens, and, where it rules, all must be "up to date." What "dear old-fashioned place" inspired our gentle singer to chant its charms we need not inquire. That such with "their nameless grace" still exist it is good to know. One wishes, daring as the wish may be, to keep them; one hopes, though vain may be the hope, that the improving (?) hand may never there display its trained dexterity, and improve them out of existence.

Our smart young gardeners, what think they of our theme? Is it of "such stuff as dreams are made of?" Possibly. But granted that it is so, I would that they momentarily closed their eyes on all that is so big now, even great Shrewsbury; upon all that is so smart and so severely trim, and hie back with me to a Gloucestershire garden. Lest any should imagine that such an illustration as I will endeavour to re-draw is not adapted to our present "up to dateness," I dare venture to assert that the flower borders would adorn in their "nameless grace" any garden in proportion to its size, from that of prince to peasant. Far removed by what seems to be a lifetime; ever journeying and settling, in the vicissitudes of life, there is one treat long self-promised, and that is to renew acquaintance some day with "the dear old-fashioned place." Ah! some day. I know it cannot be, for good men there of high and low estate have gone; yet, happily, one retrospective peep in memory's mirror flashes back the whole scene of that old garden of delight.

I do not know but what even then, when last seen, that changes were not in contemplation, for it was remarked that "Old Eph" was "on his last legs," not but what one supposes they were the identical pair which had borne him through a long and honourable life of labour, which was certainly one of love in caring for these particular flower borders, over which he ruled despotic. These ran parallel with the path, which in its turn ran centrally the full length of a long rectangular garden, some 4 acres in extent. The first time I saw these borders was at this season of the year in all their autumn glory, and during my sojourn they were a source of endless gratification, no day passing without a visit to them at early morn or dewy eve. It is but right to remark that my old friend, as I came to regard him—we had so much in common—was not the head gardener, never had been, nor ever had aspired to the post. For some forty years on the regular staff, the last decade of life found him generously allowed by the noble family he had humbly and faithfully served to work or rest on the same terms as when the bent back was straight. He chose to work, and chose wisely, as the guardian of the two long flower borders, to their decided gain.

Such a glorious vista of colours and of grace, such fragrance, it would be difficult to equal, impossible to surpass. Though possessed of a supreme contempt for all the primness and uniformity so characteristic of the bedding craze then in vigorous youth, the old man did not disdain to gather up what he could of the surplus stock of Nosegay "Geraniums," Fuchsias, Heliotropes, or what not, and "stick them in" here and there as gaps occurred, to adorn his darling borders. That these were "the dear old flowers our grand-dams knew" is doubtful, but "the dear old shrubs they loved and grew" were there. Lavender and Rosemary, Southernwood and Sweet Briar rubbed shoulders with big bushes of scented Verbena; and as for "Asters, fragrant Stocks, and darling Mignonette," they were there galore. Sunflowers, Sweet Peas, and Peas that if not sweet were bright in their perennial ramblings were there, with majestic Hollyhocks towering over all. What a medley it was surely, and here and there one detected a piece of red worsted tied round the neck of some flower or seed pod, which "Old Eph" designed to multiply, as of the best in the borders.

He was always busy on the "last legs," always genial—to me—although he was said to be a "bit cranky" by those who had no sympathy with his loose flower gardening ways. True, some tall plants had a habit of being near the walk, and short things *vice versâ*, yet it would have been a libel to say that anything was uncared for. Even a "Chaney Aster," ere it could bow its heavy head, if inclined to do so, was supported, though all his staking was very heterodox, being merely a support in the way the plants were inclined to go instead of the right and proper (?) method of bunching them upright in regimental correctitude.

It may not be seemly, some may think, to ramble on about things of the past. "We are altering, and have altered, the wildness of the old gardens," probably not a few can say; but

You may break, you may shatter the vase as you will,
The scent of the Roses will cling round it still.

—THE SQUIRE.

TRAINING FRUIT TREES—THE JUMBLE SYSTEM.

I DID not head my letter, on page 235, Decadence in Wall Tree "Culture;" someone else has done so in the rejoinders on page 260. I will therefore, if the Editor permit, try and make my point clear, as above. "E. D. S." explains it very explicitly when he says, with truth, "The crowding of branches, large and small, is a too common source of failure in the culture of wall trees," going on to say, "If branches at their formation were disposed more thinly, the management subsequently would be easier, and the results considerably increased;" or, in other words, the better and more correctly trees are trained, the less time they require in management, and the better the returns in proportion to the labour expended on them. That is my case precisely, and "E. D. S." is exactly right. He seems to know very well that a jumble of three or four times more branches than a tree ought to be burdened with must, of necessity, take more time in keeping in order than a tree with so many less to be pruned and secured to the wall and kept clean. I have not seen a man yet, and I have shared fruit tree work with a few scores, who has been able to train and attend to three or four branches, and to complete the work in the same time as he would finish one; and if it should be my fortune to discover such a prodigy, I shall not have lived and loved gardening, and written in vain.

Thank you, "E. D. S." I think you must be older than your frisky co-responder, who, after a peculiar dance in dialectics, strikes a (borrowed) dramatic attitude, and tells us with a whoop he is "off." Is he? Well, the old "gardener-hunter" is after him, intends catching him up, and making him face the "music."

And so "H. D." is really "young." He tells us so in the sixth paragraph of his declaration, as may be seen by all who care to turn to it on page 261—young, but "not vain." Oh, no; his youth forbids—or he might be. So youth is his salvation. Only "a few years ago," as he let us know in the historical paragraph, he "was in button clothes." The words cited are his own, not mine; yet this young man of bright promise—on paper has had more experience than one whom he infers, and probably with accuracy, is much older than himself. Surely the logic is rather shaky, but it is only an instalment.

Listen. This valiant young knight of the knife and the pen hastens to say in his second paragraph that while men might work as hard in gardens fifty years ago as they do now, they "certainly"—mark the word—did not work more hours. Now to be "certain" is to speak from personal knowledge; and having in view the confessions he has permitted to escape him, notwithstanding those "grey hairs," one is again tempted to wonder how old he is, and to marvel at his memory of what he saw in 1847; and even further still to wonder if he had seen a tree or a man at work at all at that time. Yet how "certain" he is about the hours of working.

It is a fact that his antiquated and inexperienced senior was training trees under the old masters within ten years of the accession of the Queen, and has, consequently, passed his jubilee as a worker—training them as a training for himself, and rejoicing in it till the creeping on of twilight in the dog-days; training them when the boundary walls of the home enclosures were the pride of their owner, his gardener, and visitors. Why? Because of their complete covering in every part from the ground upwards with properly spaced branches laden from base to extremity with handsome and much cherished fruit.

As a matter of fact, young gardeners in those far-past days were as ready to attend to wall trees, early and late when it was necessary to do so, as they are now to work overtime in thinning Grapes. They took pride in the trees then, and were as happy in working on them as "H. D." was when "handling the scissors" at four o'clock in the morning. This pride in outdoor work which then prevailed has largely vanished. It commenced waning about thirty-five years ago, when the men began to be surfeited with overtime during the bedding mania through potting scores of hours by candlelight in early spring, and then in watering, pinching, trimming and finnicking over flower beds and ribbon borders through summer evenings till the time for taking cuttings came round again. There is not much wonder that they had enough overtime to more than satisfy them. It is this lost pride in the work of training, pruning, and managing wall trees that told adversely on their condition—not at once, but in the course of time—until in innumerable instances the right word for inscribing on numbers of garden walls was Ichabod, for their glory had departed.

Talking about "want of time" for attending to wall trees, through the claims of "dinner table decorations," as accounting for the deplorable condition of so many of those trees, seems almost like trifling with the subject, though ardent young men may be firmly convinced that such talk represents the profoundest reasoning. It is a mere skimming of the surface. The unfortunate change that has been brought about is the result of a combination of influences operating in various ways for more than a generation.

A transfer of interest from one subject to another gradually, but surely, leads to a loss of pride and a weakening of zeal in respect to the subjects left behind; and this depreciation can have no other result than a loss of knowledge of a particular kind for a particular purpose. The effect of this, as applied to the training and culture of fruit trees, such as once made garden walls ornamental and profitable, is that there have been, at any time during the past twenty years and more, hundreds of young gardeners who could not train from its foundation and build up a really good wall tree to save their lives.

I do not suggest that "H. D." belongs to that category. On the contrary, I am inclined to think he knows just enough to know better, and hope it is so. He has not told us that he has planted trees, trained them from the beginning, furnished walls with them, and kept the straight thinly disposed branches in a fruitful state throughout their entire length over a period of more than twenty years. If he cannot tell us he has done this, what is his authority for attributing ignorance to those who have, and there are happily several such still existing?

True he has told us that the "guiding spirit" of this Journal has praised some splendid trees of which he had charge for "many years." Will he tell us what he means by "many?" He ought to be able to do that without difficulty, and until he does nobody will know how many his "many" counts. Then will he further tell us whether he planted those trees and trained them from infancy into their splendid condition, or whether someone else did the foundation work before his time? As a practical man he will recognise the pertinency of these questions.

Then, again, when the "spirit" praised those trees, did he, or it, do so because they were splendidly trained, but barren, and such as a man wasted his time over; or because they were both admirably trained and fruitful, and such to which intelligent labour was not misapplied? If they were "barren," why cite them as examples of the knowledge and skill of the dresser? If "fruitful" why condemn splendidly trained trees that bear crops of fruit worthy of praise? Our bright young star may choose which horn of the dilemma he prefers, and rest on it as comfortably as he can; he cannot sit on both, as they are too divergent, and if he attempted he might, perhaps, experience one of those "nasty falls" which he seems to anticipate.

As "H. D." canters away he leaves a few other footmarks behind him, but they mostly lead to the jungle, where the lion lurks. Well trained trees only last a few years; the branches die; they only bear at the tips. Such is the gist of his dolorous ditty, and he almost glories in their miserable condition. The other view is that the best trained and managed trees, like the best trained and managed Vines, are just those which remain productive the longest, and cost the least in labour. The reasoning of our reformer seems very much on the par with the crooked and many branches he loves. He seems to shudder at a straight one as a monstrosity, and appears "gone" on "side shoots" and the time-absorbing "laying in."

Did he ever see a wall of cordon Pears with the (to him) horribly straight stems roped with fruit? He would, of course, soon alter that by laying in those precious side shoots between them; and does he know that a really well trained tree is composed of a number of straight properly distanced cordons? Whether he knows or not, he would not let them stand in beautiful fruitful isolation, but lace in the side shoots, or set his labourers to do it, and call it "training;" it is in one sense worthy of the name, for it is training on the modern jumble system. On such preference, all I will say more to-night, as the hunters' moon is getting low, and the midnight chimes are dying, is *Chaçun à son goût.*—MELTON.

HARMFUL AND HARMLESS GARDEN MOTHS.—8.

"Do not forget the puss-moth," said a friend; "feline in name but not feline in nature; a cat to which gardeners have not the dislike they feel towards the four-legged one." Well, the puss-moth does occur about gardens sometimes; I have seen it in several along the Thames and New River, where the side of the ground next the stream is edged by Willows, and it no doubt visits other gardens near which grow these, or Poplars.

Seldom does a puss-moth rest on the trunk of a tree, like many moths will, till their hour of flight arrives. Guided by the mysterious force we call instinct, it prefers to secrete itself amid foliage, the thicker the better, as offering more security from a hungry bird. To some of us older entomologists this insect is associated with several metropolitan cemeteries, where the caterpillars used to be often seen upon the Weeping Willows appropriate to such places, and, since the days of Izaak Walton, or before, it has been familiar to anglers, owing to its occurrence besides rivers or brooks. (I am not aware, however, that any angler ever tried the caterpillar as bait, though it might tempt a voracious fish.) This moth, which comes out in May and June, is greyish, with yellow wing-rays and numerous dark markings, the body white, having on it black spots and bars. Nothing about it

is particularly suggestive of a cat, unless it be the head seen in profile when the insect is reposing. Probably, however, it was rather some appearance or attitude of the caterpillar that prompted the English name, for it certainly is very peculiar in form and marking. One of its singularities is the possession of a pair of horns at the tail, which the insect raises aloft while crawling, and from which it can thrust out inner horns or filaments, but they have no power of wounding or striking, being seemingly only flourished to create alarm. Now, when the puss caterpillar is but a week or two old it is nearly black, and has two little knobs, like ears, standing out on each side of the head, and, if in repose upon a leaf with the two horns folded together, it really does much resemble a crouching cat in miniature.

About August, or a month later, we may discover the full grown caterpillar on some Willow or Osier, but the species is not so abundant as to be injurious. Ruminative after eating, it then rests with both extremities elevated, and the head drawn back into a curious pink recess, having two black spots, which form the first segment of the body. Though the tail is harmless, the caterpillar has its means of defence, and if provoked, can squirt from an orifice under the chin a pungent fluid, probably acid, which, should it touch the eye or lip, causes sharp smarting. This may keep off insect enemies, perhaps birds. The cocoon, constructed upon bark, is so hard that it will turn the edge of a knife. Allied to the puss (Dicranura vinula) are some smaller moths called kittens, mostly rare, somewhat like it in markings, and in habit similar. Strolling one day in a garden at West Kensington, I took upon a Poplar the caterpillar of D. bifida, which has more variety of colour than the larger species, and feeds only at night. I should hardly hope to find this insect now about London suburbs.

September brings out the figure-of-eight moth, a moderate sized insect, owner of the long Latin name of Diloba cœruleocephala, originated by the blue head of the caterpillar, on the crown of which are two black spots. The body is green and yellow, dotted with black warts; therefore it is conspicuous upon the Hawthorn hedges, where it feeds in June, though we never see a number of them together. I have taken specimens occasionally off the Plum and Apple; abroad the species is well known as a foe of fruit trees, showing partiality for the Peach and Apricot, and requiring to be hunted after. In fact, Continental gardeners not only seek the caterpillar, but also the cocoon, made of silk and leaves, which is attached to the under side of some twig. The moth, which has its English name from two white spots on the brown fore wings, shaped rather like the figure mentioned, puts its eggs in patches of six or eight, choosing shoots upon which the leaves will expand earliest, from their position. These eggs remain through the winter, and hatch about April, according to the weather.

When the autumn breezes are thinning the leaves on our shrubs and trees, we may notice upon an Elder bush or a Honeysuckle, perhaps upon the Blackberry or some fruit tree, a twiggy-looking caterpillar, of some shade of brown, with two little points at the tail and seven humps along the body. This is the caterpillar of the swallow-tail moth, Ourapteryx sambucata, very common in the South of England. We come across it also feeding upon herbaceous plants in borders, apparently enjoying a change of diet; but feed where it may, this caterpillar invariably seeks a tree as winter approaches. Taking a place in some angle of the branches, or under a piece of loose bark, it remains motionless till April is well advanced, and becomes adult in June, spinning then a rather slight cocoon of silk, into which bits of leaves are worked; it is usually suspended like a hammock from some twig or branch. During July the largish moth flies about gardens and hedgerows, notable from its pale colour, nor is it difficult to capture. It is of a light yellow, streaked with olive brown, the hind wings having two short tails. However, it is not an insect we are called upon to destroy, the caterpillar doing no mischief worth recording.

The smaller brimstone moth (Rumia cratægata) is frequent along country roads through the summer season at intervals, and passes also into gardens, owing to its being associated with the Hawthorn, the chief or only food of the caterpillar. In colour the moth is a much brighter yellow than the preceding, with conspicuous red-brown spots. The caterpillar is brown and humped; it may be taken while the moths are on the wing, since there are two, if not three broods yearly. One of the most lovely garden moths bears the name of the Lilac Beauty (Pericallia syringaria). It is not plentiful in collections of insects, and many entomologists would be grateful to any gardener who could secure for them caterpillars of the species, young or adult. It is not possible to describe the moth; even an accurate drawing hardly exhibits the delicate markings and varied tints. July is its month of appearance, the eggs then laid upon Lilac (occasionally the Privet or Elder is selected by the parent). Caterpillars hatch generally the same year, hybernating, 'tis said, where is not exactly known; perhaps they live together. More probably their winter life is solitary. Small and greyish brown, they escape notice. The full-sized caterpillar is more showy, glossy grey or rose coloured. Near the tail end of the body are two singular hooked lumps of yellow.

Amongst the moths which have the misfortune to make themselves the victims of gaslights the thorns are prominent, some of them are familiar even to the London gaslighter. There are entomologists who devote leisure time to searching gas lamps, a rather difficult pursuit. Owing to this failing of theirs, thorn moths are often seen hovering in gardens near lit-up windows, and the species called the early thorn (Selenia illunaria) feeds upon various garden plants while a caterpillar in early summer, the moth flying during April. There is nothing thorny about any of these moths, seemingly; the name was given because most of the caterpillars have protuberances which resemble thorns on a twig, but they have no power of pricking. The September thorn (Ennomos angularia), with angled wings of brown and yellow, is a common species, which occurs even in London suburbs, the caterpillar eating Birch, Elm. and Sycamore. Later still in its time of emergence is the feathered thorn, which is abroad in October, taking this, and its Latin name of Himera pennaria, from the beautiful plumes which adorn the head; the wings are of a rich brown lined with white. Nearly allied to the thorns, but stouter in body and darker in hue, is the brindled beauty (Briston hirtaria), garbed in brown and black, which sometimes swarms during the spring about London parks and squares, leading one to think the sparrows do not eat the caterpillar, which is of conspicuous colours. It lives upon the Lime and Elm, but sometimes infests the Pear and Plum.—ENTOMOLOGIST.

MUSCAT OF ALEXANDRIA GRAPES SHANKING.

HAVING had a pretty wide experience in renovating and lifting Vines when in green leaf, and also during their resting period, I may be able to give "R. M." (page 200) some assistance in the prevention of Muscat of Alexandria Grapes shanking.

In the first place, What is shanking? It is a term well understood by gardeners, the majority of whom have had experience of it at one time or the other in their career. A house of Grapes may to all appearance be doing well, and have got over the critical stoning period. The cultivator is looking forward to having some well-finished Grapes, when suddenly the bunches collapse. At first it may be only a few mysterious brown marks that are observed, but in a few days the stems shrivel, and many of the points and shoulders of the best bunches go off in the same manner. Evidently a check has occurred to the flow of sap, which I have not the least doubt has originated at the root of the Vine.

If a mixed house of Grapes is grown, the first to become affected with shanking will be the Muscats. Some varieties of Grapes seldom or never shank. They may be overcropped, and otherwise treated badly; instead of being black they may be red, but in some instances that have come under my notice shank they will not, although the next Vine being a Muscat of Alexandria will be shanking badly. This clearly proves that the latter is a tender variety, and requires, where it is possible, special treatment. This, however, is not really necessary, as Muscat of Alexandria is planted largely in several mixed vineries under my charge. The Vines have been planted upwards of forty years; in fact, many of them are inarched on other varieties, and this season the crops are probably as satisfactory as at any time during their existence.

It may be of assistance to "R. M." if I state how this has been brought about. We have had shanking at various times, but not to any serious extent. Directly this is observed steps are taken to remedy it. I may say that the roots are inside and outside, so it is a simple matter to provide fresh soil. This is done as soon as the fruit is cut, and if possible before the leaves fall, these being kept on the Vines as long as possible by syringing and shading, so as to encourage new roots to form. The old soil is carefully removed from one of the borders, and the roots of the Vines placed in mats, which are kept constantly syringed as the work proceeds. Ample drainage is provided, and if an outside border, never more than 18 inches of soil is used. If it is possible, keep the border above the level of the surrounding land. By this means every ray of sunshine is caught, the border is warm, and the water passes away readily. Grapes grown on Vines planted in a border of this description will rarely shank provided the soil is right.

Our soil is on the strong magnesian limestone formation. But lime made from the stone, although answering admirably for building purposes, is as poison, either when used new or old, to all vegetation with which it comes in contact. Was the limestone used by "R. M." of the right quality? The loam is usually cut the previous autumn and stacked. We sometimes use a heavy and light loam in equal proportions, similar to that mentioned by "R. M.," in others only the heavy loam has been used, with no perceptible difference. To this is added charcoal, wood ashes, and broken bricks in equal parts, the latter being about the size of a hen's egg, the fine dust being sifted out. About one part of this mixture to twelve parts of soil is used. Bone meal, and quarter-inch bones in equal quantities are used in proportion of 1 stone (14 lbs.) to a large cartload of soil. This is well incorporated, and placed firmly in the border. The roots are spread out thinly in the compost, and after being finished off the whole is covered with a layer of litter or bracken sufficient to keep out the frost.

If "R. M." will make up a shallow border on the above lines, and not use any horse or pig manure, which in his case doubtless did more harm than good by keeping the border cold and stagnant, he will, I have no doubt, be able to grow good Muscat of Alexandria Grapes without being troubled with shanking for some time to come. But he must first take steps to keep the Elm roots out of the Vine border, or they will soon impoverish it to such an extent that it will be impossible to grow good Muscat Grapes without constantly renewing the border.—S., *Yorks.*

ORCHIDS

Cycnoches chlorochilon.

When visiting the Chelsea nursery of Messrs. J. Veitch & Sons, Ltd., I noticed a plant of this peculiar and interesting Orchid in flower amongst many others. The Swan Orchid, as it is termed, always attracts general attention by the curious structure of the flowers. It is a native of Demerara, from whence it was imported upwards of half a century ago. It is, however, by no means common, being usually grown in collections merely as a novelty. C. chlorochilon (fig. 41) has stout conical pseudo-bulbs bearing the flowers at the top in pairs; the sepals and petals are bright green, the lip broad and yellowish with a dark blotch at the base, and directed to the upper portion of the flower. The column is slender, curved, green, and in the position where the lip is usually seen in Orchid flowers. The plant is of strong habit, requiring a compost of peat and sphagnum, with the temperature of the Cattleya house, supplying abundance of water and moderate shade.—Orchidist.

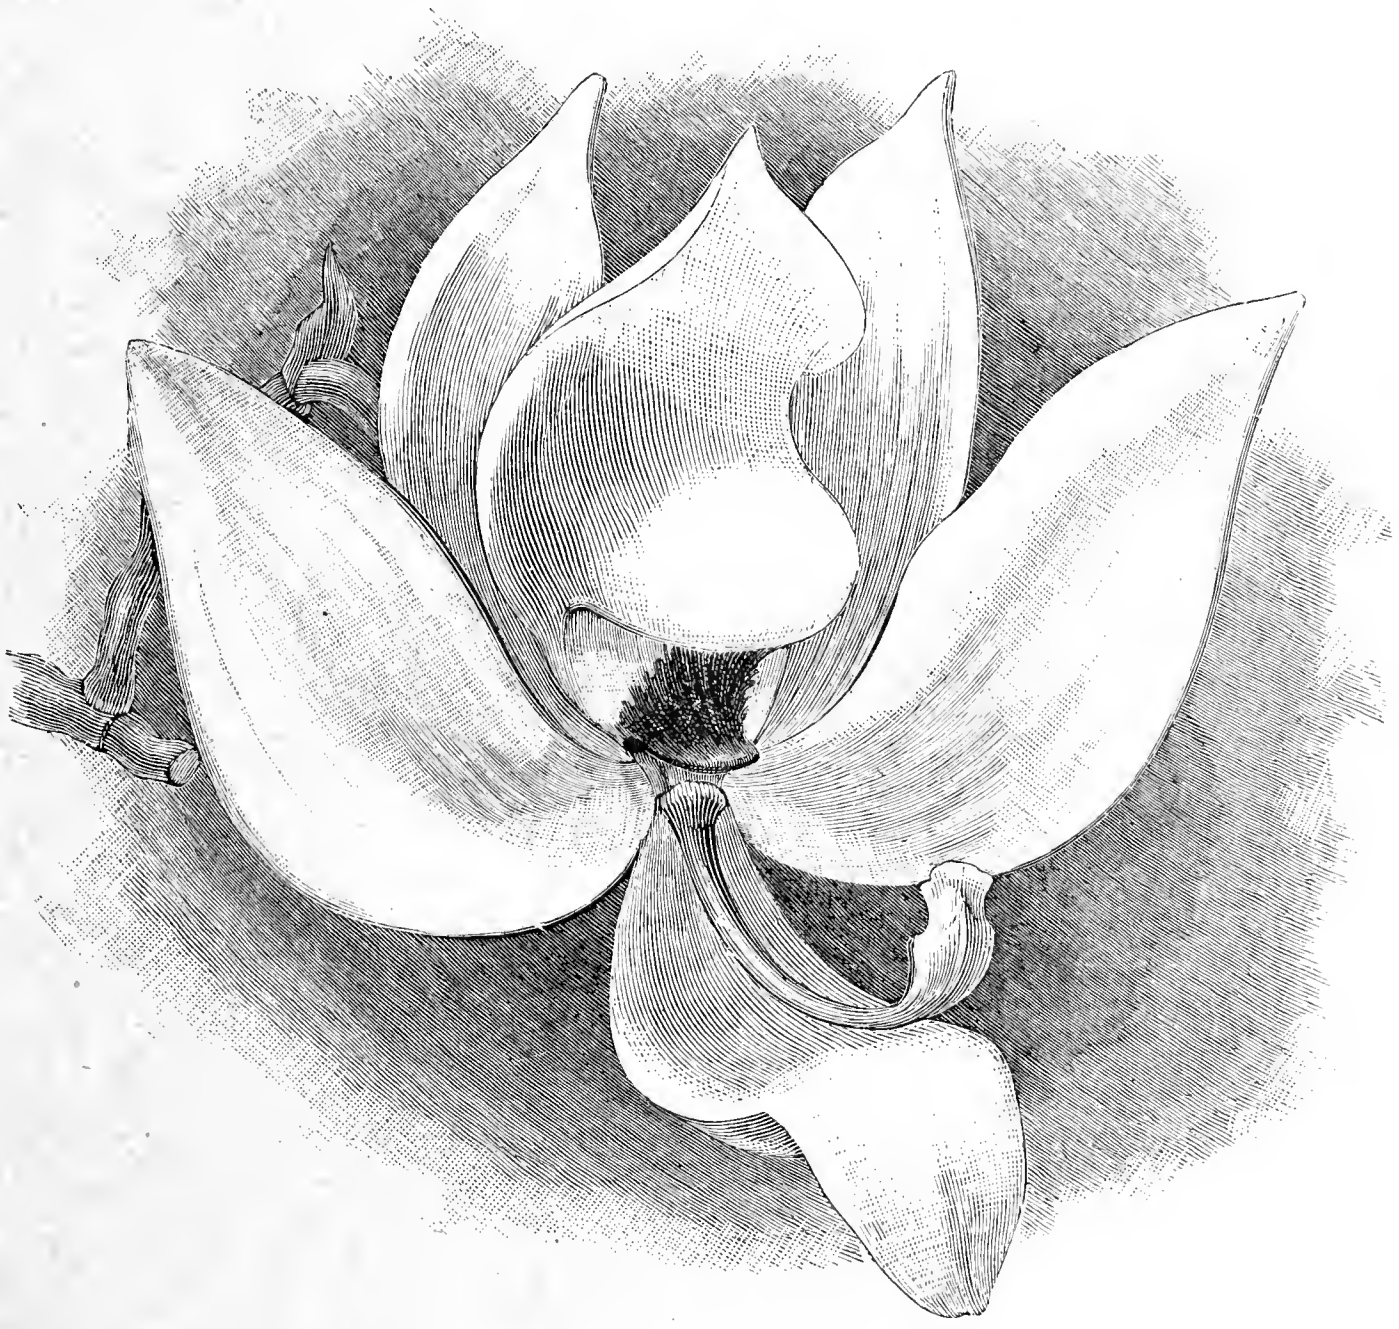

Fig. 41.—Cycnoches chlorochilon.

The Mexican Lælias.

There can be no question about the beauty of this section of Lælia, or their utility in keeping up a fine display for many months in the year, a great part of their flowering season being at a time when really good Orchids are not at their best. They form quite a distinct set botanically, and must be cultivated differently from that group usually grown in company with the labiata section of Cattleyas. Not many are yet in bloom, but I have one or two spikes of L. autumnalis open considerably in advance of their usual flowering season, and this prompts me to send a note on their culture.

It must be understood at the outset that all the plants here referred to grow further north of the equator than do the species with which I have compared them. Not only this, but they are also found at great elevations above sea level, where a much lower range of temperature exists than in the lower region about the coast of Mexico. The veteran Orchid collector Roezl, who has many times visited these regions, says of some of the species that "they grow at altitudes between 7000 and 8000 feet where severe frosts often occur at night." But presumably these frosts are of very short duration, as in most of these upland habitats of Orchids day and night temperatures to a certain extent, and to a greater one, winter and summer readings are more regular than in the valleys.

There can be no doubt that if a house can be set apart entirely to this section of Lælias and one or two other Orchid species with which we are not just now concerned, much better results will be attained than if they are grown in a house with a general collection. This of course is only possible in large collections, growers of smaller quantities of plants having usually to make the most of the conveniences to hand. For this reason I cannot give details that will suit every case, but must leave individual readers to make the best arrangements they can under existing circumstances.

A clear almost unbroken light is of the utmost importance, both during the growing and resting season. While such as L. anceps are growing the plants delight in having the sunshine full upon the foliage—always provided that this is not of the immature kind produced by heavy shading and undue heat—a very moist atmosphere, and abundant ventilation. Rather difficult to keep up, someone may say; and so it is, but it can, and must be, managed if the best results are to be looked for. The grower who lowers his shading in fitful weather, closes his house, damps down, and then leaves the plants to their own device, will never grow the Mexican Lælias properly.

During summer the house should have a little air on constantly night and day, this being increased early in the morning, the floors, stages, and walls of the house well damped, and the shading kept off the roof as long as possible. The foliage then keeps cool until late in the day, while had the house remained closed until the sun reached it there is an upward rush of the temperature, at once necessitating early shading. Many times in the heat of summer I have left the blind up on the Mexican house until nearly midday, then lowered them for a couple of hours, and shut up with ample moisture.

In the coldest winter weather one may as a rule keep a little air on during the greater part of the day, the pipes being gently heated to keep the house nicely warm, and the plants so arranged that every ray of light reaches them. The roots at this time will be kept nearly dry, watering being necessary only at very long intervals. While growing freely, on the other hand, they may, if the plants are properly potted, be watered almost daily. The atmosphere of the house, too, may be kept much drier in the winter, what little moisture is necessary being given early in the day, so that it has time to dry a little from about the plants before nightfall.

There are one or two species—L. majalis as an example—that are benefited by being placed out of doors for a few weeks after the growth is fully made. The lovely flowers of this plant are never so freely produced as when this is done. The plants of all the Mexican kinds like a shallow compost; one that soon runs dry after water is given, and allows plenty of fresh air to reach the roots. Pans, pots, or baskets may be used for them. They are also frequently grown on rough wooden blocks, while the trellised rafts now made in

all sizes are excellent receptacles for the plants. A great advantage of the latter is they can be suspended at a corresponding angle to that of the roof, and thus obtain the maximum of light.

Equal parts of peat fibre and sphagnum moss is the best compost in either case, only a very little of this being placed on the rafts; just enough to form a setting for the rhizomes. In the pots or pans about an inch for the smaller sizes, with a little more for larger ones, suffices, and in this case plenty of small rough charcoal or crocks must be mixed with the more compressible material. Clean every part of the plant after it is taken from the old compost, and cut away all decaying roots. These few cardinal points in their culture properly grasped, and altered only so far as to meet individual circumstances, will enable anyone interested to take up their culture with every prospect of success.—H. R. R.

An Orchid Painting from Brussels.

A very beautiful plate of Orchids has been sent us by Mons. Lucien Linden of Brussels, representing some of the best of the firm's introductions during this year. There are two forms of Odontoglossum crispum, one named Lueiani and the other Lindeni, both beautiful varieties splendidly reproduced. Besides these the plate contains Cypripedium insigne aureum and Cattleya Trianæ Imperator. As a whole the plate is a great credit to the artists, printers, and to Mons. Linden, for it is a veritable work of art.

Cypripediums and Skin Irritation.

Among many other papers in the "Proceedings of the Indiana Academy of Science," dated 1894, but only just received, is one by Mr. T. D. MacDougal, showing that various species of Cypripedium have an irritant action upon the human skin. It was found that when the leaves of C. spectabile were rubbed lightly upon the skin of the wrist, arm, face, or ear the person experimented upon was usually "poisoned" in a degree corresponding to the manner of application, and in a time varying from ten to twelve hours. There could be no doubt about the unpleasant effects produced by the leaves, for Mr. MacDougal soon found that he could not obtain subjects willing to sacrifice their feelings upon the altar of scientific knowledge. He was able to prove, however, that similar painful effects were produced by C. pubescens and C. parviflorum. To ascertain whether the effect was due to the mechanical injury resulting from piercing the skin by the pointed hairs upon the leaves, or to the corrosive action of the secretion found on the outside of the globular tips of the glandular hairs, separate tests were made by material from C. spectabile. The hairs of each kind were taken from the leaf by means of a pair of fine forceps, and the tip pressed against the skin. Irritation was found to result from the contact of the glandular hair only. It was found, further, that the irritant action of the plant increased with the development of the plant, and reached its maximum with the formation of the seed pod, from which it is inferred that this is a device for the protection of the reproductive bodies during the period from pollination to the maturity of the seeds.—("Nature.")

VEGETABLES FOR HOME AND EXHIBITION.

PARSNIPS AND TURNIPS.

Nothing adds more to the attractiveness of a collection of vegetables than sound, clean, and straight roots of Parsnips, and no autumn collection can be quite complete without them. Well worked land is the first consideratiou to successful Parsnip culture. The reason is obvious, as the roots naturally strike downwards to a considerable depth, and if the medium is hard through lack of cultivation or of a very stiff or clayey nature, obstruction is placed in the way of the downward tendency of the roots, and forked unshapely specimens are the result. Liberal use of crude manure has the same effect, therefore the advice given in reference to other tap-rooted vegetables is applicable here—viz., grow your Parsnips on ground that has been heavily manured for some previous crop, or, failing that, bury the feeding material to a fair depth beneath the surface. Parsnips generally do well in soil that contains lime, and a dressing of this useful commodity on the quarter where the vegetables are to be grown will invariably give good results. In the Channel Islands seaweed is largely used as a manure for this crop, and is said to answer admirably.

In order to obtain large specimens, some growers sow the seeds in September, but this method cannot be generally recommended, as so many of the plants run to seed before the roots are developed. The end of February or during March, according to the weather, is a suitable time for sowing, having previously taken advantage of favourable opportunities for breaking down the soil to a friable condition. Abundance of room is another rule that growers may follow with advantage, as growing too closely together is not only conducive to small, unshapely roots, but is also an incentive to that enemy of Parsnip growers—canker. If the seeds are sown in rows 18 inches asunder and the plants subsequently thinned to 1 foot apart, roots may be grown in the ordinary bed of ample size and quality sufficient for the exhibition table, and it is altogether a mistaken idea to think there is anything gained by allowing the plants to remain in a crowded condition.

Free use of the Dutch hoe is the chief requisite during the summer until this becomes impracticable through the abundance of foliage. In growing for exhibition purposes an occasional top-dressing of two parts superphosphate of lime and one part muriate of potash at the rate of 3 ozs. to the yard of drill is beneficial, and in dry weather applications of liquid manure from the farmyard or soot water may be used with advantage. The roots do not reach maturity till October, though drawing may commence in September. It is a good plan to take up part of the crop in November and store in sand for future use, as was recommended for Beet and Carrots. The remainder may remain in the ground, as the severest frost does them no harm, but on the other hand adds to their sweetness. None, however, should be left after February or March, as they will then commence growing. In storing great care should be exercised that the roots are not allowed to become dry, or they will shrivel and be stringy when cut. The best varieties for exhibition or home use are the Student and Sutton's Tender and True.

Mention has already been made of canker, and in it we have the most formidable disease to which the plant is subject. In some seasons and localities Parsnips suffer worse than in others, and as the work of destruction is going on underneath the surface, there appears to be no effectual means of cure. As in many other cases, the best method is to render the conditions of cultivation as favourable as possible for the sturdy growth of the plants. Change of soil for this crop is always advisable, more particularly so when canker makes its appearance, and a dressing of lime at the rate of about two bushels to the rod will be found beneficial. Also trench the ground so as to bury the living spores of the fungi beneath the surface. In preparing Parsnips for the show table straight unblemished roots of even size should be chosen. Care must be taken in digging not to damage them in any way or break off the thin tender tip of the root, as this detracts from their appearance, and beyond washing them clean no further preparation is necessary.

Amongst the many vegetable crops none is easier to manage than the Turnip so far as culture is concerned, and the chief point is to secure a succession fit for table the whole year round, as Turnips are always in request. Even in the winter, when green stuff generally is scarce, the blanched succulent tops of these vegetables are highly appreciated as a substitute for Seakale, and as a green vegetable Turnip tops are extensively offered for sale in the London markets. When young and tender they are very palatable, being often invaluable when severe frost has stripped the garden of its supply of Brassicas. Little need be said about the preparation of Turnips for show, as everyone knows that none other than sound young specimens are of any use. This season has been a bad one for Turnips, and they have, in consequence, been scarce and of inferior quality. The protracted drought has not been conducive to the rapid growth that is necessary in order to obtain sound sweet Turnips, while that natural and deadly enemy of the crop, the Turnip flea, has thriven amazingly.

As already stated, succession is an important point in Turnip culture, and in order to keep the kitchen continually supplied a start may be made as early as January by sowing on a gentle hotbed, as is usual with early Radishes. Care must, however, be taken, as overheat will produce rapid growth of the tops, but no roots will be formed. In February another sowing may be made in a sheltered position outdoors, taking care that the ground is friable and light, and if preceded by some other crop, such as Celery, that has been subject to thorough working of the soil, so much the better. Sowings must follow at intervals through March, April, and May, in order to keep up a constant supply. For autumn use sow in June, while the end of July and August should be chosen for inserting the seeds that are to produce the winter supply. Generally speaking Turnips are sown in rows from 12 to 15 inches apart, and in successful management more depends on timely and judicious thinning than anything else. Great care is necessary in this operation, and where two or three are growing together they must be reduced to a single plant, and be finally left with a distance of from 6 to 12 inches between them, according to the general size attained by the variety.

The tropical sunshine of this summer has been disastrous to Turnips, particularly on very light soils, and watering has been absolutely necessary. Where artificial means have to be adopted for supplying moisture it should be thoroughly done. Lifting and storing may be carried out on the lines recommended for other root crops, a dry atmosphere being necessary, with no other protection except what is necessary to exclude frost. A portion of the crop may be left in the ground, and the Turnips pulled as required for use. In severe winters it is well not to destroy those not required for use, as by leaving them in the ground the green tops may serve as useful vegetables in case of emergency, after which they can be turned into the ground when digging. Like many other vegetables of this kind

varieties are legion, almost every seedsman claiming to have his own strain. For the first sowings Early Milan and Early Snowball are good white varieties, and the white Strap-leaf is excellent as a succession; while among the coloured kinds Red Globe, Orange Jelly, and All the Year Round will provide variety sufficient for ordinary requirements.

The Turnip crop is subject to attacks from various enemies, perhaps the worst of which is the Turnip flea, Haltica nemorum. Disastrous effects of this pest have been seen this summer, thus proving the statement that favourable conditions of culture are the best preventive against insect and other pests. The exceptional drought stopped the growth of the plants and encouraged the spread of the insects, with the result that Turnip beds presented a pitiable appearance. As a preventive it is a good plan to sprinkle the plants with dry lime, wood ashes, or soot in the morning, when they are wet with dew, as anything of a dusty nature is distasteful to the pest.

Attacks of the slime fungus, known as "finger-and-toes," are frequent in light and sandy soil; and here, again, nothing serves so well as favourable conditions of culture, thereby insuring free and rapid growth. Where a crop is affected by finger-and-toes a complete change of ground is the first consideration, and no infested roots should be left on the ground, otherwise the spores are washed into the soil, and the remainder of the crop suffers in consequence. All infested roots should be gathered and burnt, and the ground either trenched, so as to completely bury all traces of the disease, or be subjected to a dressing of gas lime, at the rate of about 1 lb. to the square yard, in the winter, leaving it on the surface for about a month before forking it in. Though good cultivation is the best preventive against all ills to which vegetables are heir, we cannot always insure them, as the capriciousness of climate often proves an incentive even after our most strenuous efforts. If anything is worth doing, however, it is worth doing well, and the lesson is thoroughly applicable in the cultivation of this useful vegetable, whether for home or exhibition.—Grower and Judge.

NOTES ON BULBS.

Putting the many distinct bulbous plants into one large group we should probably find that it comprised the most popular plants in cultivation, for one or more representatives of it will be found in almost every garden or greenhouse throughout the country. Especially is this the case during the spring months, when so-called Dutch bulbs are making such beautiful displays. The expression "so-called" is used advisedly, for it is somewhat of a misnomer now that so many thousands of Daffodils and Snowdrops particularly, which were some time back largely procured from Holland, are grown in the British Isles. However, as the time is with us when this section of the bulbous flowers is being dealt with, it is proposed in a few notes to mention cultural details and give selections of varieties for various purposes that may be of assistance to some readers of the *Journal of Horticulture*.

It will be thought by many persons that the culture of plants so widely grown must be thoroughly understood, but this is not the case, as can easily be proved by the failures that are constantly occurring both in large and small establishments. Two of these come to mind at this moment, and will be cited here as warnings to others who may feel disposed to adopt similar tactics. Let us take the case of a so-called professional grower first. It was only this spring that his failure with Hyacinths was observed, and for which he blamed the bulbs, the bulb merchant, the soil, the pots, the houses—everything and everybody in fact but himself, who was entirely in fault. In September excellent bulbs were procured, but potting was postponed from time to time until the end of December, of course owing to the pressure of other work. Then all was bustle and hurry. The already weakened bulbs were potted and placed, covered with brown paper, in a very warm house to make up for lost time. The results were interesting, but not beautiful, as every good grower may imagine—indeed, it was the most extraordinary collection of Hyacinths the writer has seen. Despite the efforts that were made to convince him to the contrary this professional gardener (?) persisted in changing the bulb merchant, and was quite decided to place his order in another quarter this season, and it is probable the bulb merchant who supplied them will be thankful if he does so.

Now for the amateur, who was a man of quite another calibre. Everything that could be thought of was done to insure a superb display, and the result was looked for by the writer and friends, as well as the owner, with great interest. All went well (apparently) until a week or two after the removal of the pots from the cocoa-nut fibre refuse in which they had been plunged. There were the stout growths, but, wonderful to relate, scarcely a movement was made by any single shoot, though one or two did attempt to throw up a flower, but failed. Speculations as to the cause were abundant, and during the owner's momentary absence one day an inquisitive visitor took hold of a shoot to feel if it were firm, when the bulb came easily out of the soil. It was immediately replaced, but not before it was seen that there was not one root, and it was the same with the many others that were tested. By dint of persistent persuasion it was eventually learned that a heavy dose of artificial manure had been added to the compost, and with really lamentable results.

These two cases will perhaps bring a smile to the faces of some growers who have not made such mistakes, but they serve to illustrate what may follow negligence or ignorance in bulb culture. If such things have been done, they may be again, though not by the same men, and it is to aid in their prevention that these notes are being penned. Though the cultural details to be given have been proved over many seasons, it is not to be suggested that they are the best; others may do just as well by different methods of procedure and will not feel disposed to change. Let them not do so, such is not desired. For the unfortunate and the inexperienced this writing is done, and if these and the skilled growers should gather some useful hints the object in view will have been achieved. After this rather lengthy preamble we must settle down to business and give pride of place to the always admired

Hyacinths.

The first essential towards success in growing Hyacinths either in pots, glasses, or in the open ground, is the purchase of sound bulbs. These, be it understood, need not necessarily be very large. The main thing to look for is solidity. To secure this the earlier the orders are placed in the dealer's hands the better, as it cannot be doubted that the best go first, despite the fact that it is always affirmed that no picking is done. Having secured the bulbs requisite, potting (it is with pot culture that we shall deal for a time) must commence at once, and where many are grown some may be placed in pots immediately, the remainder waiting about a fortnight. The question of compost is an extremely debateable one, but it has been found that three parts of sound loam, one part of decomposed leaf mould, with a goodly amount of coarse sand and small pieces of charcoal, suits them admirably if thoroughly incorporated. Some excellent cultivators advocate decayed manure in preference to leaf mould, but my practice has been to feed when the plants are advancing in growth, as will be referred to later.

Priority might perhaps have been given to pots and crocks over soil, but it does not matter particularly, so long as they are referred to. No need to tell the intelligent cultivator that everything ought to be scrupulously clean to commence with; but there are others, and one of them was heard to say recently, who ought to have known better, that he could not see the use of washing soil off pots and putting more in them directly. As to size of pot, much latitude is permissible, for given good soil and proper attention excellent results may be had by the utilisation of either 4, 4½, or 5-inch pots, these being one bulb for each, or say three of medium size for a 6-inch pot. For choice I would take the 4½ size, and should expect satisfactory blooms if a start had been made with first grade bulbs and proper compost. After carefully placing the crocks in the pots in the customary way, the soil must be prevented getting amongst them by having a layer of moss or the rougher portions of the compost put on, and if this can in turn be dusted over with soot so much the better.

The stage at which potting is commenced in earnest may now be considered as reached, and if the soil be in proper condition, that is to say, neither wet nor dry, it is an operation that does not call for much difficulty—indeed, it is much easier to do than to describe. When completed, the apex of the bulb may just protrude through the soil, therefore the amount of soil that is placed in the pot and on which the bulb will rest must be governed by its size. Do not make this mould very hard or the roots cannot enter freely; have it firm and no more. Then place in the bulb, surrounding it with soil to the level mentioned, which should be about ¾ of an inch from the top of the receptacle. Let the soil be firm and finished off smoothly for the sake of appearance. Water ought not to be required, but if the soil is very dry it is advisable to apply some before plunging the pots. Some growers always have a cushion of sand for the base of the bulb to rest upon, but I have found no particular advantage arise therefrom.

One of three things may be used of which to make the plunging bed. These are cocoa-nut fibre refuse, leaf mould, or coal ashes, and the first named is certainly the best and the cleanest. Whatever it is let the pots be completely covered to the depth of about 4 inches, and if, as is best, the bed is outside, put any rough material over the whole to throw off the heavy rains. If the soil were in proper condition no water will be needed until the bulbs are ready to be brought from the bed, when, soon after, a thorough soaking may be applied. From four to seven weeks are usually long enough for several healthy roots with a stout top shoot to have been emitted, and when this stage is reached they must immediately be taken from their resting place.

At this period the attention must be of the closest so as to prevent

any mishap occurring that may mar the future well-being of the plants. To bring them into full light at once is almost suicidal, as it is to allow the mould to be like dust at one time and mud at another. For the first few days put brown paper over the pots, following with white paper, and eventually discarding the shading entirely. The only object in its use is to inure the plants to the light to which they are unaccustomed. In a very few days a move will be made, the crown will expand and elongate, and no check should now be permitted whether the plants are in a greenhouse or in a room. Water judiciously, using clear and manure water alternately, the latter being given very weak or it will do more damage than good. I pin my faith on guano, ¼ oz. to a gallon, and soot water. Either would perhaps do alone, but I am a believer in a simple change of diet as well for my bulbs as for myself.—H. Rose.

(To be continued.)

AUTUMN FLOWERS.

The rain and storm which so lately stole the glory of the autumn flowers have gone. Sunlight, chastened though it is, and soft warm winds have come by day. Yet everything reminds us that we are on the brink of winter and shall soon be plunged into its dreary days. The nights grow long and chill. The swallows have gathered on the house-tops and gone in search of a sunnier clime. The Virginian Creepers have changed their colouring, and cover with blood-red leaves the garden or house front wall. Humbler plants have followed suit, while others have assumed a different colouring. We hear with sad ear the rustle of the falling leaf, though it drops to the earth to the accompaniment of the redbreast's song; for the little bird is back again to spend the winter beside our homes. We look with yearning eyes at the flowers we are so soon to lose. How we shall miss them when they are gone. They grow dearer every year, and their silent companionship more satisfying as time goes on. Yet why meet trouble half-way? Though the nights grow more chilly, and shorter and cooler the sunny days, there are many flowers yet; even some still to come to give us heart while we await the coming of spring.

There are soft-coloured Asters, pillars or pyramids of bloom; golden St. John's Worts, showy Sunflowers, white and blush and pink Japan Anemones—none more beautiful than those of purest white. Hardy Fuchsias are very beautiful, with the coral-red and purple drooping flowers, to which gather in crowds the humble bees in search of store for the coming wintry days. Great bushes of Hydrangeas are in some of the gardens; by the sea winter for these has few terrors. The lace-like Gypsophila paniculata is nearly over, but the graceful Statices still give us airy bouquets of bloom.

Early Chrysanthemums, which, by the way, do not seem to grow much in favour, are masses of colour, and Rudbeckias and Heleniums stand near, to give witness that North America can give us flowers as well as China and Japan. So say the Phloxes, too, although the original flowers are small beside those from the florists' hands. There are yet some Bellflowers, too, although their glory is greatly over. A few of the dwarfer ones are again in bloom, and the exquisite flowers of the Platycodons attest the worth of the genus which includes them among its attractive flowers.

The stateliness of the Gladiolus is of a different kind from that of the Kniphofias, or Torch Lilies, which have thrust their flaming flowers high above their long reed-like leaves. Gay, too, are the Montbretias, which remind us, as do many other plants as we look at them, of the achievements of the gardener's art, which has given them birth. Meadow Saffrons, Crocuses, Violas, Golden Rods, Sea Hollies—these, and more besides, are yet in flower. In gardens in which annuals and half-hardy flowers are largely grown we have other types of beauty still. Dahlias, Sweet Peas, Dianthuses, veined Salpiglossis, Nemesias, Clarkias, Godetias; beauties innumerable fill up the feast of Flora's maturest time.

Where can we begin, and with what shall our thoughts be occupied in detail, as we try to fix them on a few flowers of the time? The true hardy Chrysanthemums of the latifolium and maximum type have of late, in the hands of the seedling raiser, given us so many varieties that we fear that, before long, they must be reckoned among the florists' flowers, which only a specialist in that particular flower can hope to say much about. The day of "named" flowers in some races has gone by, or is rapidly passing away, so high is the standard of excellence which has been attained in raising seedling forms. When we see these great Ox-Eye Daisies numbered by the dozen or two we feel that such a time may be at hand for them too. Even now it takes a good one to be distinct enough to find for itself a space in gardens where already these Chrysanthemums are well represented. Amongst the finest I have lately seen is Mrs. Head. It is large and of the purest white in its ray petals. Yet it is not in size or in purity that it is distinguishable from others now in gardens. It is from a peculiarly pretty and informal poise of these florets that it earns and deserves a place in our gardens, and merits its use as a cut flower to fill large vases or for other decorative effects.

It seems some time since I last spoke in detail of any of the St. John's Worts, whose golden blooms are incidentally referred to in a preceding line. Long have they been held in favour by the superstitious on account of their marvellous powers to ward off or drive away evil. Traditions and legends have clustered around the plant—not in our own country alone, but in others beside. Its flowers reminded the people in olden times of the sun with its brightness and power to dispel darkness and evil of various kinds. Very beautiful are these sunny blooms with their exquisite boss-like centres; a beauty reinforced in most of the species by the pleasant-looking green leaves. There is much variety among the species; some trailing over the ground; others with erect, herbaceous stems, and others, again, with shrubby or sub-shrubby habit.

For notice now Hypericum olympicum is selected, not because it is the best—for who can venture to say as much of any—but because it is beautiful enough and good enough for any to admire and praise. Less informal than some are its starry flowers, with their small central boss and conspicuous stamens. The colour is less deep, too, than in some species, but a good plant with a number of flowers fully open attracts notice with its clear yellow flowers, which are larger in size than one would expect from the plant before it comes into bloom. It is by repute a greenhouse species, but is hardy in my garden on a rockery with an eastern aspect, where it has lived and bloomed for several years. It has round stems, and has rather elliptical-lanceolate leaves, which are full of pellucid dots, for which the genus is remarkable. A light soil with a proportion of peat in it is the compost in which it is grown here. It comes, I believe, from the Bithynian Olympus, whence it was introduced in 1706, and is easily raised from seed.

A few lines which remain may be profitably devoted to a mention of Polygonum amplexicaule—the Stem-clasping Knotweed—a Himalayan plant worth growing, but seldom seen in gardens. For some years I have seen it in the garden of Captain Stewart of Shambellie, Newabbey, N.B., where there is a good collection of herbaceous plants. The specimen here is the rose-red form, but, according to Nicholson's "Dictionary of Gardening," there is also a white variety. It may be mentioned that the above work has this plant marked with an asterisk, thus singling it out as especially good or distinct. It comes into flower in August and blooms into October, and the flowers, which are produced in racemes, will often be found useful for cutting purposes. Its height at Shambellie is about 3 feet—from this down to 2 feet being its normal growth. The name is derived from the upper leaves being sessile and amplexicaul. P. amplexicaule is far from plentiful, and is but seldom to be found in nurserymen's catalogues.

These are but, as it were, fragments of the feast picked up as we go among the flowers. All too soon will they pass away for the year, but till the sad time has come we may enjoy the smiles of the autumn flowers, saddened though these seem by the thought of approaching decay.—S. Arnott.

PLANTS FOR WALLS.

Almost every garden has its iron or wood trellis, pillars, arches, ornamental or rustic wood and iron-work, which in most instances it is desirable to cover with climbers. There are arcade fronts, arbours, bowers, stumps and trunks of old trees; some objects pretty in themselves, which it is considered in good taste to enrich with lively beauty, and other subjects objectionable, which when clothed with foliage and flowers become ornamental. Walls too high or too low, sunny or shaded, never look so well as when so adorned.

It is not always advisable to cover with climbing or other plants every surface suitable for their training and successful growth; and in the case of buildings it is not judicious to train plants over an architectural mansion—its principal parts, perhaps no part, ought to be planted against, for as a work of art it should be seen in all its details. Buildings which have many enrichments should not have these covered, though it may be advisable to clothe the intervening spaces with foliage; and in the case of brick buildings with stone dressings, the plants ought to be confined to the brick portion only, and they should only be taken up the height of the stonework, and not so as to cross it with the view of covering the upper part of the building. The plinth, too, if of stone, ought not to be hidden, but the stems of the plants made to cross it in the angles, or in the least objectionable manner. A well-designed, well-built mansion needs no plant ornamentation; but there are some buildings so mixed in character, and so inartistic, that it is desirable to cover them with foliage. Plain buildings, especially if low, may, as a rule, be clothed with plants, as these give an appearance of height, or prevent the want of elevation in the building from being so much noticed. Nothing, however, is so incongruous as to have tall and low-growing plants on the same surface. They must all attain one height, and be kept to that by pruning. I do not think they look well trained higher than the first-floor window sills, or if there be a string course, they should be kept under it; but if they are taken higher

then they should not stop until the cornice or projecting roof is reached. Of that they should be kept clear, the whole wall being covered equally to one height.

In garden architecture there are many surfaces suitable for the training of plants. Walls built for division, or for affording shelter, when unplanted are cold and wearying to the eye, but become cheering when covered with plants. Besides walls, there are buildings which present surfaces with different aspects suitable for plants, some admirably suited for a class of shrubs whose flowers are handsome and desirable for bouquets, and which cannot be depended on from plants in the open ground. Even the low walls of greenhouses or other plant houses are rendered less cool and uninviting when clothed with either foliage or bloom. Nothing, in my opinion, is so ugly as a bare wall; it offers nothing which can interest, and a badly covered wall is not much better.

Another great defect is that of employing plants without paying any regard to the character of the building, for as buildings vary, so ought the subjects; for instance, a building constructed of light-coloured materials will be subdued or toned down by planting subjects with bright green foliage and red-coloured flowers, as Roses, or such evergreens as Escallonias, not seeking too great a contrast, like that which would result from a close and heavy mantling of Pyracantha, or Ivy. Massive buildings should be covered with close-growing, heavy-foliaged evergreens, as Pyracantha, Ivy, and Magnolia, whilst a light and elegant structure should be clothed with plants like the Clematises and Honeysuckles, introducing a few evergreens for winter effect.

Some persons object to climbers and plants against buildings on account of their making the walls damp. How far that opinion may be correct I cannot say. I am aware that plants covering a wall will shade, and to a great extent deprive it of heat and air; it will be covered with moss sooner than one exposed to the sun's action, but that is because it is shaded, and not because the plants make it moist. I am of opinion that they would tend to make a wall dry rather than damp. The only way in which I think the walls are rendered damp is by their not being cut off at or a little above the ground line from damp ascending from the soil, and with plants this dampness will be increased by placing soil close to the wall instead of the loose rubbish from the building. From the watering of the plants, too, there will be more dampness than if there were no plants. That, however, shows, not that plants make walls damp, but injudicious building, for all buildings ought to have the ascent of damp from the ground cut off by a layer of asphalt as high as, if not higher than, the ground level, and above that the border for the plants should not be raised. I have seen the ground outside taken above the line of the asphalt or cement, and the walls made wet in consequence for several feet up. If the ascent of damp from the ground be cut off, and the soil not taken above the point at which it is cut off, no one will have need to complain of climbers making walls damp.

A proper border must be made for the plants. It is useless to plant them against a wall, if for a considerable depth and distance there is nothing but rubble. It ought to be removed, and proper soil put in to the extent of at least a yard from the wall, and to the same depth, placing in the bottom about 6 inches of rubble for drainage, and then a layer of turf or the rougher parts of the compost. The latter must vary somewhat in its composition, but most climbers will succeed in two-fifths of turf cut about 3 inches thick from a pasture where the soil is a rich loam, neither heavy nor light; one-fifth short manure, such as that from a Mushroom bed, or the fresh droppings from a stable as free of straw as possible; one-fifth leaf mould, and one-fifth sharp sand. The turf should be chopped up rather small, and all the materials well blended together. The border should be formed of this compost, using the materials fresh, without laying them in a heap to decay, but the upper part of the border should be of finer soil to the depth of about 6 inches. The compost just described, laid up for three months, would be suitable for the purpose, chopping it up and making it rather fine. It would not grow all climbers, for it would be too rich for some, and too open for others, and not properly constituted for a few; but it can be made lighter by adding sand, omitting some of the ingredients, and replacing with others of a suitable nature.

Not only should proper soil be provided for the plants to grow in, but it should be in quantity sufficient to support the plants to full size. The width and depth named, 3 feet, will in most cases be sufficient, but there will be cases in which a greater quantity of soil must be supplied for the roots. For instance, if the soil is wholly unsuitable, it should be taken out twice the width, and replaced with fresh. In some positions the plants have to be planted under gravel walks; then the soil ought to be taken out, proper provision made for the roots, and when the plants are put in, the gravel can be returned. The same remarks apply to places which are grassed over, and due regard must be paid to furnishing the plants with proper soil, and the grass should not be placed close to the stem, but an opening must be left all round. There are soils which will only need to be trenched, working in enriching material, such as manure or leaf mould; and where it is a good loam it will be sufficient to trench it 2 feet deep, and mix it with manure, or add the kind of soil required by the plants.

As regards the time for planting climbers, as they are usually grown in pots, planting may be performed at any season, but it is best done when they are about to commence growth, say in March, or earlier, according to the season. It is a good plan to plant them out before they have grown much, and still better if they have not grown at all. The roots should be spread out, the soil shaken from them without injuring the fibres, and a good watering given at planting, also afterwards in dry weather, so as to promote free growth.—G.

ISLE OF WIGHT HORTICULTURAL IMPROVEMENT ASSOCIATION.

THE members of the above Association had a most enjoyable outing on Thursday last, September 16th. By the kind permission of W. H. Myers, Esq., M.P., they paid a visit to Swanmore Park, Bishop's Waltham. The party of about thirty members, including their esteemed President, Dr. Groves, B.A., J.P., and Hon. Sec., Mr. S. Heaton, F.R.H.S., met at Cowes, and proceeded by steamboat to Southampton, and thence by two brakes to Swanmore. Passing on the way through Botley the market growers were noticed busy making their new plantations of Strawberries, taking the runners from the old beds and dibbling them in, as they would Cabbage plants.

A pleasant two and a half hours drive brought the pilgrims to Swanmore, where they were met at the entrance gate by the gardener and steward, Mr. E. Molyneux, V.M.H., and conducted to a pavilion on the cricket ground, where an excellent cold collation had been arranged, Dr. Groves taking the chair and Mr. C. Orchard the vice-chair. After the repast generously provided, the Islanders enjoyed a most delightful stroll through the grounds.

The mansion, which is just now being enlarged, was aglow with a highly coloured Ampelopsis, showing well by the side of the dark green Ivy and other creepers. In the neatly kept flower gardens some harmonious and elegant arrangements were admired. A combination of carpet and subtropical bedding, in which such plants as the grey Eucalyptus, Variegated Maize, Arundos, Eulalias, Solanums, and others, brightened with very fine flowering Begonias, on a groundwork of Sedums and Alternantheras were employed with pleasing effect. The herbaceous borders, which included amongst others a very fine collection of Michaelmas Daisies of every known variety were equally admired. It is not the right season to see the houses at their best, but the range of vineries indicates what can and has been done in Grape growing at Swanmore.

Apples appeared more plentiful here than in the Island. The larger trees in the home orchard were bearing fine crops, some of the more conspicuous being Blenheim Pippin, Mère de Ménage, Warner's King, Cox's Orange Pippin, King of the Pippins, Tom Putt, Cellini, Peasgood's Nonesuch, and several others.

The collection of Chrysanthemums in pots naturally came in for especial notice. Mr. Molyneux's fame as a cultivator and exhibitor has long been associated with this popular flower. The collection comprises nearly all the leading varieties of Japanese and Incurved, the height of the plants ranging from 2 to 10 feet. Their general condition may be described as not gross, but hard and boney; and the well-ripened wood is sure to produce some well-shaped blooms in due season.

The poultry runs, stocked with the leading varieties of fowls, fine Aylesbury and Pekin ducks, plump geese, fit for Michaelmas, as well as stalwart turkeys and the interesting peafowl, came in for no small share of admiration, as did the well made and neatly thatched hay and corn ricks. The general appearance of the group so impressed one veteran that he said he "should like to have a *likeness* took of 'em."

Time would not allow of an inspection of the newly planted orchard, consisting of many hundreds of the best kind of Apples for market purposes, one of which, Lord Grosvenor, is in much favour at Swanmore. Unfortunately some of the party had to leave earlier than the others to save the early boat to the Island, so only a section could accept Mr. and Mrs. Molyneux's hospitality, and the time came all too soon to leave this delightful spot.

Before departing Dr. Groves proposed a vote of thanks to Mr. Myers for his kindness in allowing them to come to see his beautiful garden, and to Mr. Molyneux for his attention in showing and describing to them the different objects which were of much interest. Mr. Molyneux, in reply, said he was delighted to do anything to advance horticulture or to please horticultural friends, and if they had reaped any profit or pleasure he was only too pleased.

To Mr. Heaton the thanks of the members are due for arranging everything for this most enjoyable outing.—C. O.

TROPÆOLUM SPECIOSUM.

THIS charming creeping or climbing plant is coveted by many who see the luxuriance with which it grows in the northern portions of the United Kingdom. It seems to revel in the moist atmosphere of the west of Scotland; but once it becomes established in more southern or drier districts, it is quite as beautiful although less vigorous. It looks its best, perhaps, when grown against a dark background, such as that formed by evergreen shrubs or hedges. A pretty object is a little Ivy-covered arbour, over which trail the crimson flowers of the Tropæolum. Equally fine is a view in an old manse garden of the same, running among some fine Irish Yews, and decorating these with festoons of scarlet blooms.

Establishing this creeper often requires patience, especially on a dry soil. Planting in firm well-trodden ground in March or April generally suits better than doing it in autumn. No one need be disappointed if there is little growth for two or three years. Once it begins to grow freely it increases with great rapidity, and unless planted where it can do no harm will become so rampant as to be troublesome. Lately I saw it against a wall behind a border planted with Anemone japonica alba. It had spread over the whole bed, and the gardener seemed inclined to think he was to be sympathised with, and not to be congratulated upon because of its vigour.—S. ARNOTT.

Notes & Gleanings

EDITORIAL NOTICE.

It is particularly desired that all communications, parcels, catalogues, and newspapers intended for the **EDITOR,** *be sent direct to* S, **Rose Hill Road, Wandsworth, S.W.**

EVENTS OF THE WEEK.—Though not precisely within the next week we deem it advisable to give our readers another reminder that the Crystal Palace Fruit Show opens on Thursday, September 30th. We hope to see a magnificent display of all kinds of British grown fruit that are now in season.

—— WEATHER IN LONDON.—Not very much rain has fallen in the last seven days. There was a light shower on Saturday evening, while on Sunday night rain fell rather heavily for some time. Monday and Tuesday were bright and dull alternately, but rain did not fall on either day. Wednesday again was fine.

—— LILIUMS AND ROSES.—I have just read two articles in the current issue of the *Journal of Horticulture*. One of them is written by "D., *Deal*," and what he writes so interestingly should be read by every ardent cultivator of that loveliest of Lilies, Lilium auratum. The other is on the subject of garden Roses, by the great Chrysanthemum specialist, Mr. Edwin Molyneux. With what he says of Turner's Crimson Rambler I entirely coincide. It is truly a superbly ornamental Rose, and keeps its brilliant colour much longer than any climber within the range of my acquaintance. Bardou Job and Gustave Regis are also of great value for garden decoration; but though beautiful in the bud they are almost single when fully blown. A much finer Rose than either, and fuller in the centre, is Madame Pernet Ducher, a French Hybrid Tea.—DAVID R. WILLIAMSON.

—— AMORPHA CANESCENS. This is, without doubt, the most beautiful and distinct of the hardy Amorphas. It is a native of the United States, and is found growing on the prairies of Michigan and Wisconsin, and is there known as the "Lead Plant." It grows to a height of from 2½ to 3 feet. The branches are sub-shrubby, and in England die to the ground during winter. The leaves are pinnate, and composed of twenty or more pairs of ovate leaflets, which are covered with an abundance of white silky down. The flowers are produced in terminal panicles, the branches of which range from 3 to 6 inches in length. The individual flowers are small and bright purple, with yellow stamens. They are densely packed on the peduncles in a cylindrical manner. The purple corolla and yellow stamens, together with the white leaves, produce a most charming effect. The flowers are at their best during August. It is best propagated from seeds sown in a little heat in spring. The young plants should be kept in pots until they are twelve months old; they should then be planted in sandy loam. When about three years old they begin to flower well.—D. K.

—— DEATH OF MR. JAMES COCKER.—The news will be received with general regret of the death, at the age of sixty-four, which took place on the 15th inst. at Sunnypark, Aberdeen, of Mr. James Cocker, senior partner of the firm of James Cocker & Sons, nurserymen, seedsmen, and florists, Aberdeen. He had been ailing for the past two years, and latterly had been unable to attend to business. Deceased was born at Corse, parish of Forgue, in 1832. He entered the business of his father—who was founder of the firm—at the nursery at Sunnypark, and afterwards went as a journeyman to Cloncaird Castle, Ayrshire. He also spent several years in London studying the various branches of the nursery business. He went into partnership with his father and brother about twenty-six years ago, a partnership which continued until the death of his father sixteen years ago. He then started business on his own account, taking his three sons—James, William, and Alexander—into partnership with him. His eldest son James predeceased him three years ago, but William and Alexander are still actively engaged in the business. Mr. Cocker was a very enthusiastic and successful cultivator of Dahlias, Pansies, Pinks, and Carnations, while latterly herbaceous plants and Roses—for which his firm was known over the kingdom—claimed his chief attention. He had also great success as a hybridist, having raised many Roses, Pansies, Violas, Pentstemons, and Phloxes.

—— A WARNING.—Several allotment holders at Kent House, Beckenham, have this season lost portions of their produce, and the police have failed to make any arrest. One allottee evidently intends taking the law in his own hands. He has put up a board with the following notice: "The Lord helps those who help themselves; but the Lord help that man I catch helping himself to my Marrows.'

—— APPLE KERRY PIPPIN.—"D." in his note on page 265 is in error in stating this variety had not been previously shown in the flavour competition. Last year it came before the judges on two occasions, but failed to get an award. It seems scarcely credible that gardeners can be so ignorant respecting the Veitch competition. I see the prizes were won last year (from July to December) by sixteen different exhibitors from diverse parts of the country, so that the competition is not so much restricted.—A COUNTRY GARDENER.

—— THE FLAX INDUSTRY.—It is said that an effort is being made to revive the Flax industry in the eastern counties, particularly in Lincolnshire. At present the counties in which Flax is chiefly grown are Yorkshire, Essex, Suffolk, and Somerset. More is cultivated in the East and West Ridings of Yorkshire than anywhere else. In Great Britain last year only 1800 acres were under cultivation, but in Ireland the acreage where Flax was grown was 73,301, though that was 25,000 acres less than the previous year.

—— SUTTONS' EPICURE BEAN.—Having grown this excellent climbing Bean for three seasons, I am more than ever impressed with its value on every point. As a cropper it is marvellous, the clusters of light green beans hanging in the greatest profusion. Long after the ordinary French Bean is past its best Epicure is in fine condition, and it is a rarity to find a stringy pod. I should imagine that a variety of Butter Bean has been used as one of the parents, as when cooked they are somewhat of a paler colour. It is of such usefulness at the present time and until frost cuts it down, that I can with confidence recommend all unacquainted with this variety to make a note of it for next season.—R. P. R., *Liverpool.*

—— THE JAPANESE FLORAL CALENDAR.—Details are given of the Japanese floral calendar in the "Far East," and as the Japanese are notoriously fond of flowers, also of Maple leaves, a summary of this may be read with interest. January is represented by the Pine, and on New Year's Day every house is decorated with its branches. Its never-fading colour is considered as the emblem of eternal prosperity and long life. February is associated with Plum blossoms, which stand for virtue and purity. March is sacred to the Peach blossom, to which young girls are likened. April is the month for Cherry blossoms, the most beloved of any flower. May follows with Wistaria, and June with the Iris and Water Lilies. The festival of the Iris is dedicated to the boys, just as the Peach celebration is consecrated to young girls. August and September are identified with flowering species of Hibiscus and Azalea. October is the month of the Chrysanthemum, the Royal Flower of Japan, which figures in the crest of the Imperial family. There is a national festival of Chrysanthemums, which greatly stimulates the loyalty of the nation. November is distinguished by its Maple leaves, while December is associated with Camellias, which blossom out of doors though often covered with snow.

— ERIOBOTRYA JAPONICA.—In favoured localities the Loquat, or Japanese Quince, as this plant is popularly called, makes a handsome evergreen bush or wall plant when grown outside, and with slight protection comes through all but the most severe winters unharmed. It is seldom, however, that flowers are produced outside in England, probably from the wood not being sufficiently ripened, and from the flowering period being very late in the year. When grown under glass, though, flowers and fruit are sometimes produced. In the Winter Garden at Kew a bush 12 feet high is now in flower. The inflorescences number from forty-five to fifty. The flowers are white, three-quarters of an inch or more across, and almond scented. They are produced thickly in panicles from the ends of the branches. The panicles when young are erect and covered with a grey felty pubescence. As they become older and the flowers open the pubescence becomes brown and the panicles slightly pendent. The fruit, when ripe, is somewhat ovate, orange yellow, about the size of a walnut, and edible. It ripens in the early spring. Although much more interesting when in flower or fruit, it is worth growing solely for the sake of its foliage. The leaves are about 10 inches in length by 3½ inches in width, and covered, particularly on the under surface, with a grey felty pubescence. The Kew plant is growing in a well drained bed in fairly heavy loam.—D. K.

—— Sweet Peas.—Can any of the Journal readers give an opinion regarding the Sweet Peas raised by a well-known American firm and sold in sealed packets last spring by British seedsmen? I have had no experience except from the packets of mixed varieties, but have been disappointed with the flowers produced. They are no advance upon Eckford's or Laxton's well proved strains. It may be, however, that the wet season we have had in my district has been more unfavourable to the American varieties than to the others. I should be grateful for the result of the experience of others.—A. Hardiman.

—— Wakefield Paxton Society.—Programme of meetings for the third quarter, session 1897. Meetings are held at eight o'clock prompt. September 25th: From Westgate to Kirkgate, via Chicago, illustrated by lantern slides; Mr. F. H. Wigham. October 2nd: Exhibition of Autumn Leaves and Fruits; essay by Mr. A. E. Benney, Bradford. October 9th: The Apple and Pear; Mr. A. H. Pearson, Chilwell Nurseries. October 16th: The Natural History of a Country Lane, illustrated by lantern slides; Mr. H. Crowther, F.R.M.S., Leeds. October 23rd: The Potato; exhibition of specimens, and discussion. October 30th: The Planting of Fruit Grounds; Mr. H. J. Monson, Yorkshire College. November 6th: Root Crops in the Kitchen Garden; Mr. J. G. Brown. November 13th: The Chrysanthemum Exhibition. November 20th: A Week in Hamburg, illustrated by lantern slides; Mr. H. S. Goodyear. November 27th: Some Useful Wild Plants; Mr. G. Bott.

—— Carnation Disease.—Some investigations by Mr. A. F. Woods of the Division of Vegetable Pathology in the Department of Agriculture, seem to indicate that the so-called "bacteriosis" of Carnations, first described by Dr. Arthur in 1889, is not due to bacteria, but is a direct result of injuries to the plant by thrips or aphides. In a paper read at the recent meeting of the American Association for the Advancement of Science, Mr. Woods brought out the fact that neither fungi nor bacteria are present in the earlier stages of the disease, and that their presence is not constant as the disease advances. A disease with all the characteristics of this bacteriosis, excepting the presence of bacteria, can be produced by aphides, and since the injuries in their earlier stages are not accompanied by bacteria, the aphides cannot be charged with carrying any infectious germ. The Carnation is readily influenced by extraneous conditions, and the reaction to the injuries of aphides and thrips vary largely, and plants carelessly grown suffer more seriously from punctures by the aphis than vigorous plants do. The sum of the matter is, that the greatest care should be used in selecting and propagating stock, in furnishing conditions for vigorous growth, and in keeping down aphides and thrips. It is these insects, and not bacteria, with which the practical grower must contend. Of course, good stock and good conditions of growth can never be neglected, and Mr. Woods' investigations give emphasis to what growers already know—that the disease is often the result of neglect, and that the way to have healthy plants is to give the closest attention to every detail of culture.—("Garden and Forest.")

—— The Fruit and Tomato Crops of Guernsey.—One can now speak with a little more certainty of what our season has been like. I believe the quantity of Tomatoes exported has been very large, but as the area of glass has also much increased since this time last year, there is no proof that the crop has been any better than that of last year—in fact, many establishments report the contrary. The long dull, damp, spell of weather we had from February to the end of May was much against a good "set" of fruit in the early houses, and not a few crops were spoiled by black stripe and other diseases. From some cause or other the later crops, taken generally, are not coming up to expectation. Fine robust plants may be seen without a flower "set" upon them. These are being pulled up in disgust, and the houses filled with Chrysanthemums, of which there are a large quantity being grown, greatly in excess of any previous year. The cultivation of Lilium auratum is also much increasing, so that we are looking forward to a busy autumn and winter, flower export trade being done. Grapes have been of very mixed quality, many Hamburghs in the unheated houses refusing to colour, others shanking badly. But with the little knowledge most of our Guernsey growers possess of growing Grapes on scientific principles, failures are not to be wondered at, and but for a good natured climate they would come off much worse than they do. With regard to outdoor fruit, Apples are a fair crop, but as these are chiefly of the cider kinds scarcely any are exported. Pears are scantily grown, and are a moderate crop this year. Briefly, our own market, through the winter months, is chiefly dependent on supplies of fruit we get from Jersey and our neighbours the French.—X.

—— Gardening Appointments.—Mr. T. H. Davis has been appointed gardener to G. S. Eastcourt, Esq., Eastcourt Park, Tetbury. Mr. W. J. Meer has been appointed gardener to Major C. D. Shenton, Evercreech House, Bath.

—— Lysimachia clethroides.—This Loosestrife is rather an uncommon plant in the herbaceous border, though not very rare. The peculiar manner in which the extreme point of its flower droops while expanding renders it exceedingly interesting. As expansion takes place the flower spike assumes an erect habit. The flower is of the same form as a Clethra, hence its name, and the plant blooms during August. The height altogether is a yard under good cultivation. We have it growing at the back of the rockery, the heavy soil suiting it well. It is of a creeping habit under the surface, where its roots run freely, therefore no trouble to propagate it is experienced; in fact, it is liable to spread a little too rapidly.—E.

—— Shirley Gardeners' Association.—The monthly meeting of the above Society was held at the Parish Rooms, Shirley, Southampton, on Monday, the 20th inst., Mr. B. Ladhams presiding over a good attendance of the members. There was an exhibition of vegetables for prizes in the form of one silver and three bronze medals, presented by Messrs. Toogood & Sons, Southampton, for which there were seven entries. The silver medal and certificate was awarded to G. W. Fleming, Esq., Chilworth Manor (gardener, Mr. W. Mitchell); bronze medal to W. F. G. Spranger, Esq., Springhill, Southampton (gardener, Mr. Harry Curtis); bronze medal C. G. Stuart Menteth, Esq., J.P., Rownham's Mount (gardener, Mr. W. Risbridger). These were for six sorts of vegetables open to all members. There was a useful and interesting discussion on the exhibits.

LOCKE PARK, BARNSLEY.

Able and painstaking are the two adjectives that occur to one's mind as most fitted to apply to the gentleman in charge of this park, after a visit has been paid to it. A huge mound of Ivy first arrests the eye with no relief for at all events the first few minutes, but soon a long vista of horticultural splendour is unveiled, an altogether unsuspected panorama of artistic bedding, relieved and enhanced by the high banks studded with Hedera, Ilex, Retinosporas, Aucubas, and other shrubs. Alternately convex and concave, as it were, like the sides of natural rocks, are the beds arranged, the effect at every few steps being constantly changing. Lobelia pumila magnifica, the golden Calceolarias, white Milkmaid Violas, Dell's Beet, Cineraria maritima, Bijou and Flower of Spring Zonals, Pyrethrum selaginoides, East Lothian Stocks, ever and ever higher, until the most effective background that could be wished is furnished by Helianthus, Nicotiana affinis, and Dahlias in variety, surmounted as aforesaid by the healthy shrubs and ornamental trees in great variety. About 200 yards of this "feast for the horticultural mind," accompanied by the courteous, and, at times, jocular gardener in charge, Mr. Henshall, is at the time most enjoyable, and an experience on which the memory loves to dwell.

Passing cool graceful masses of such Ferns as Lastreas, Aspleniums, Scolopendriums, Athyriums and Blechnums in friendly rivalry, we emerge into a well asphalted walk, that I understand the public of Barnsley has the right of traversing by night and day.

About forty acres comprise this beautiful park, given by two generous donors for the public of Barnsley for ever. A few acres were added not many years ago, the gift of J. T. Wentworth, Esq., of Stainborough Hall, a sight of which I had from the centre of the park—an imposing Norman edifice of considerable historic interest. For a study in landscape work we have only to ascend the Locke Tower that was presented in 1877. The view from the summit is delightful. There may perhaps be fully too many Lombardy Poplars, erect as Sir Oracle. The blending of the trees and shrubs, which for the most part are luxuriant, is admirable. Very noticeable are the fine specimen Hollies, and the judicious planting of the ornamental Prunus, Golden Elder, Acers, and Mountain Ash. True, there are occasional corners in the belts and exposed borders that pourtray the effects of the wind's ravages, but on the whole the wise pruning and annual thinning is carried out carefully and well.

The glass structures must not be omitted. They are conveniently situated near Mr. Henshall's house, and are necessary for the propagation of plants for the beds and borders; but by no means all the glass is devoted to such work. Many plants are grown for the enjoyment of visitors. Noticeable were richly coloured Crotons, Cannas (Madame Crozy and Australie being splendid), Coleus, some fine Dracænas Lindeni, Baptisti, Shepherdi, Youngi, and amabilis; rich Caladiums, Cocos flexuosa and Weddelliana; Aralia Veitchi, Anthurium Scherzerianum, Allamanda Williamsi (well flowered), Nepenthes Mastersiana, with Odontoglossums and Cypripediums in great variety.

In another compartment were to be seen large Fuchsias and Zonal Pelargoniums, profusely flowered Begonias, Heliotropes, Salvias, Ivy-leaved Pelargoniums, and healthy red and white Lapagerias. About 450 plants of Chrysanthemums are well grown, and include the best and most up-to-date varieties. A light repast and inspection of Mr. Henshall's not inconsiderable library concluded a most enjoyable and memorable visit to this beautiful Park.—Albert Upstone.

APPLE TREE TWIG AND BRANCH,

AND SOME THINGS ON THEM.

THE specimens sent some time ago for examination and report, in reply to the query of "F. W. C."—namely, "What is the matter with the enclosed Apple tree twigs and branch?" are so characteristic of the condition to which the British Apple tree may be reduced by the attacks of two of its most inveterate enemies, that portrayal of them cannot be otherwise than useful.

The twig (fig. 42. *A*) had been cut off by a knife at a point where the wood and bark were quite clean and healthy, and consisted of one to four-year-old growth, indicated by the figures 1–4. At the parts *a* mussel scale was securely fixed; at *b* some scale had been removed, imparting a mottled appearance, and the wood there had become more or less swollen, with the bark wrinkled and cracked. The only living buds were those marked *c*, numerous spurs (*d*) having died.

On removing some of the mussel scale (*B*) there fell out fine dust-like particles (*e*), just visible to the unaided eye, some white eggs, and black dross. As there was nothing more discernible on the twig, except a minute pale pink speck in a crack (which will be referred to), I cut off a small slice of bark (*C*), and on examining it with a lens enlarging six diameters, was struck by the small size of the scale; they were not larger than one-third the normal size of those on vigorous Apple trees, which may be due to poverty of food.

Turning over a scale (*D*) some eggs (*f*) fell out. Looking at the upturned scale with a lens magnifying 20 diameters, it appeared as shown at *E*, the lily white eggs (*g*) being very conspicuous. They were noticed to vary greatly in form, therefore I placed three (*F*) on a glass slide, and looked at them through a lens enlarging 150 diameters. Their size was especially noticeable, being at least two-thirds less than normal ones. They appeared white (without light thrown on them by the reflector from below), and had each a bright luminous spot (*h*). Turning on the light the eggs were seen to be opaque (*i*), with a thick outside shell (*j*) and yolk (*k*) inside, the nucleus (*l*) appearing very distinctly and evidently working. That was all there was to be seen as regards the scale at the time, but sufficient for identification, namely:—Mussel Scale. *Mytilapsis pomorum*, Bouché.

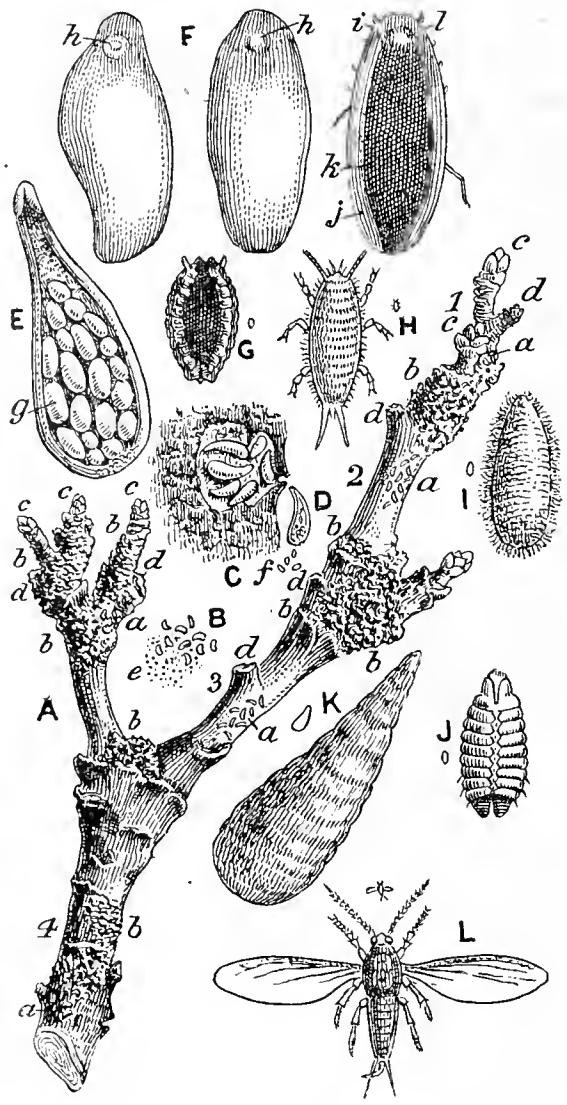

FIG. 42.—APPLE TREE TWIG INFESTED BY MUSSEL SCALE.

Referenees:—*A*, twig, showing: year's growths 1—4; *a*, fixed scale; *b*, place where scale removed; *c*, living buds; *d*, dead spurs. *B*, matured scale; *e*, dust-like contents. *C*, small slice of bark with scale enlarged 4 diameters. *D*, under side of a scale; *f*, eggs (enlarged 4 diameters). *E*, the same magnified 20 times; *g*, eggs. *F*, eggs (enlarged 100 times), showing: *h*, luminous spot; *i*, opaque (as seen illumined)—*j*, outside shell; *k*, yolk; *l*, nucleus = Mytilapsis pomorum in embryo. *G*, form of egg before insect emerges. *H*, larva. *I*, female or scale "fixed." *J*, pupa form of insect. *K*, hard brown shell = scale. *L*, male = Mytilapsis pomorum—female *J*. (*G*—*L* magnified, natural size on side.)

It is hatched from the eggs about the middle of May, sometimes earlier, and at others later, according to season, the egg usually assuming a woodlouse-like form before the larva emerges, as shown at *G*. The larva (*H*) is white at first, becoming yellowish or grey, as also do the eggs before hatching, and it has six legs, jointed antennæ, side bristles, and caudal hairs—an elongated, woodlouse-like creature. The larvæ, which, escaping the attention of carnivorous insects and birds, soon settle down, always on living bark where the sap flows by to buds or fruits, and push their beaks into the tissues of the bark, causing the tree to strive repair the injury done by growth of cellular tissue, and the twig below may become swollen more or less, whilst where the insects are it gets smaller. Sometimes the larvæ fix on the footstalks of the fruit, especially on Pears, and even on the fruit itself, and it means diminution of the supplies of nutriment to the immediate parts and those above, hence resulting in depression.

The creature that fixes itself is the female (*I*), which turns to pupa, and commences to form a scale, fastening it with threads to the bark, with openings between, so that breathing is not interfered with. If we turn up one of such soft scale (*J*) it is seen the insect has dispensed with the legs and other appurtenances, retaining only three pairs of bristles on the hinder part of the body, and has developed an enormous beak (when magnified), just the right length to reach the sap; also note the body is plainly segmented. Still it grows that is the scale, and at last becomes a hard brown shell (*K*), more or less curved and wrinkled across. The female produces ova or eggs, going on until there is not a particle of her body left but the head, then it is all over for that year or cycle, and there is nothing beneath the scale but eggs, a little white cottony matter, and some dirt.

Of course we have not as yet seen a Mytilapsis pomorum, only a bevy of eggs, larvæ, and perfect female. At *L* is the "lord" of the mussel scale family. Like to see one? Then get some strips of bright tin plate, about 3 inches wide and a foot long, paint both sides with a smear formed of sweet oil and resin, melted. putting on with a brush lightly, and it then shines like gold and silver, placing in the forks of the Apple tree, when, or soon after, the females fix themselves. Look carefully with a magnifying glass, and amid the host of captured creatures may be found the exact model of the insect shown at *L*. Perhaps it may be the first time, or probably not for years, for male scale insects are about as difficult to catch as the females are the reverse.

"F. W. C." wishes to know what he can do in his case as preventive and remedial. The case is such a complicated one, as we shall show presently, that it is difficult to confine our remarks to the mussel scale, but as there are instances where there is it without the other things, we may dispose of the scale first, and mention for avoidance the scraping of the bark with any kind of implement, for it is a bad old practice. Nevertheless, some ancient plans are good, one of the best the potash and soda solution of old-fashioned gardeners taken by Britain's sons and daughters to the ends of the earth, and given back to us in stronger and better acting form. I allude to Mr. Leonard Coates' solution of caustic soda and commercial potash, first propounded by him in the *Journal of Horticulture*. The old method was to place wood ashes in a wooden vessel and pour on enough rain water to cover them, allowing to steep two or three days and then strain off the clear liquid—potash lye. Measure the lye, and in another vessel place in as many ounces of washing soda as quarts of liquor measured, and pour on as much boiling water as the measure of potash lye, and when dissolved pour into the vessel containing the last named. While warm apply with a scrubbing brush to all affected parts of the tree, and with a half worn paint-brush to the spurs, applying thoroughly on a fine day while the trees are quite dormant.

Mr. Leonard Coates' solution has the advantage of being stronger, and can be sprayed on, therefore the work is more expeditiously performed. The formula is:—Half a pound each of caustic soda, 98 per cent. purity, and commercial potash—carbonate of potash or pearlash. Dissolve the articles in a small quantity of water separately, add together when dissolved, and dilute with hot water to 5 gallons, applying at a temperature of 130° by means of a spraying apparatus, wetting every part of the tree on a fine day, or when dry and not frozen, the buds being quite dormant. The best time, however, for killing scale is when they are in the larval state, soon after they have hatched, spraying with soluble petroleum or any approved insecticide about the middle of May, and at intervals of ten days to the middle of June. The scale are then as easily killed as aphides; but when they get fixed, resin washes are most effective on soft scale, forming an impervious coating over the insects and smothering them. If nothing be done in summer time, then there is the above-mentioned solution, also the old-fashioned never-failing dressing of boiled linseed oil, applied with a brush as soon as the trees are leafless. I have tried raw petroleum, and not found it clear some badly infested Pear trees on a wall, probably because it did not get under the scale and reach the eggs. It does not smother them like the oil, or dry them up like something caustic.

Now we will return to the living twig, *A* (fig. 42). Remember, it is alive, or scale would not be there, or the wood green, with buds at its extremities. Let there be no mistake about this matter, for it is the crux of the subject, and has reference only to a little pink speck in a crack of the bark; yet a very old acquaintance, and of disastrous consequences to Apple trees and many other species of widely different genera. For clearness, it is shown on a spur (where it occurs), *M* (fig. 43), enlarged four diameters. There are plenty of mussel scale insects (*m*), and these may easily be mistaken as the cause of the swelling (*n*). They certainly have made minute holes in the bark by their beaks, and something else has got through one of such openings, and this was the cause of the spurs dying. This I satisfied myself about by removing a slice of bark, and there, between the bark and wood, was fungal hyphæ.

We come to the crack (*o*), and a pale pink speck in it shown white (*p*). Removing that it appeared the size shown at *N*, and when magnified six diameters as at *O*, while at *P* it is represented twenty times and at *Q* 67 times larger than as seen by the unaided eye. It was noticed as a young fungal plant not fully developed, but sufficiently so for identification, the head having a paler stem spreading upwards into a somewhat globose crown, and when full-blown (*R*, enlarged twenty diameters), covered with a delicate mealy bloom. The body, at its base, penetrates to the inner bark, whence the mycelial threads spread in all directions, confined, however, to the cortical tissues, and not entering the

woody ones beneath. This gives rise to the swelling on the part of the plant—an abnormal growth of cellular and even woody matter, the fungal hyphæ always showing its appreciation by remaining in the inner bark or cambial cells between the bark and wood. Thus it exploits the host. The head of the fungoid body, examined with a lens enlarging 400 diameters, will be found to consist of delicate parallel threads compacted together to form the stem and head, some of which are simple, others branched (*S*), bearing upon them delicate little bodies—conidia (*q*), and is the fungus complete — capable of reproduction or continuation by seed (spores). The conidia are whitish and diaphanous, which on the pale pink stratum have a beautiful luminous appearance, and easily seen with the unaided eye. The whole is the fungus plant named *Tuberculariu expallens*, Fries.

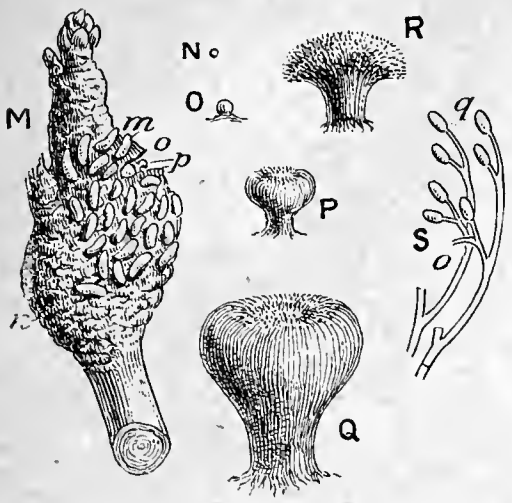

FIG. 43.—EARLY FRUCTIFYING FORM OF CANKER FUNGUS ON APPLE TREE TWIG.

References:—*M*, spur (enlarged 4 diameters); *m*, mussel scale; *n*, swelling (due to fungal hyphæ); *o*, crack in bark; *p*, pale pink speck. *N*, speck (natural size). *O*, the same enlarged 4 diameters. *P*, ditto, 20 times. *Q*, ditto, 67 diameters. *R*, full-blown fungus (enlarged 20 diameters). *S*, portion of fructification (enlarged 267 times); *q*, conidia or spores = Tuberculuria expallans.

When the conidia are dispersed by wind, they, or some of them, may fall on Apple or other trees affording the essential food of the Tuberculuria, and, lodging in a crack or hole made by the beak of a female mussel scale, push a germ-tube into the crevices of the bark, and thus enter by sheer force of growth into the tissues of the inner bark. But frost and many other things may occur to upset fungal schemes, therefore this one has prepared for casualties by providing subglobose bodies springing from a common stroma or stem, and following on after the conidia are shed. These subglobose bodies are perithecia, in which the final or complete stage of the fungus is perfected, so that the seed (spores) produced are practically frost, wet, and drought-proof while they remain in the perithecium, and only when the weather is warm and the air suffused by "a soft glow of moisture" do they come forth, rising and sailing in the air by means provided for that purpose.

Now we come to examining "F. W. C.'s" Apple tree branch (*T*, fig. 44). It had been sawn off at bottom (*r*), and broken off at the top (*s*), and mainly consisted of a scar. The bark was off the lower part (*t*), but on the upper portion (*u*), was not dead, yet dried, evidently wanting sap. The part above the scar must have received nourishment in the last two years through the inner wood, or have lived upon the stored matter above for that period.

The scar represents what had occurred during the previous eight years, six on the wood (1-6), and two on the bark (7 and 8), each representing the advance of something at the expense of the living branch. The something had entered at *v*, and had come out after eight seasons, as indicated by the small circles on the bark—some on the two-year-old (*w*), and others on the, at least, nine years old (*x*), even on the inside edge of a splintered part (*y*), and on the older bark adhering in a patch (*z*) to the scar.

These little bright pink pimples are round, and they break through the bark erumpantly, being clustered together as shown at *U*, enlarged four diameters. They become redder with age—a glowing crimson, each a perithecium (a receptacle formed of one valve). All are alike, but varying considerably in size, and when mature become brown or blackish, somewhat warted or pimpled and hard. They are attached to a common stroma, and the mycelia spreads inwards between the bark and wood, but growth is outwards in this instance, the hyphæ compacted around the pyrithecium to form the shell, granular, and inside that a sort of membrane, but all cells, as also is the internal contents.

A perithecium is shown at *V*, enlarged 67 diameters, with a sort of nipple at the apex (*a*), which becomes more or less depressed, and ultimately serves as the aperture by which the spores escape into the air. If cut through when immature it appears as figured at *W*, externally granular (*b*), and internally filled with a gelatinous nucleus (*c*). Later on the nucleus develops fructification (*X*), cylindrical asci (*d*), each enclosing eight elliptical sporidia (spores) closely packed together, and mixed with slender septate threads, simple or branched, and called paraphyses (*e*), enlarged 134 diameters. Thus the perfect form is ultimately reached, and it is the canker fungus, *Nectria ditissima*.

In the perithecium the plant may rest a considerable time—months, if not years, but the spores are always liberated when the external conditions are favourable for development, and they, or some of them, always manage to find out the varieties of Apples most vulnerable, including some having the richest sap—Ribston Pippin, Cox's Orange Pippin, Golden Pippin, and the Reinettes. What time the spores go forth has not clearly been ascertained, but there comes a right time and proper place for the spore (*Y*, enlarged 334 diameters), on an Apple tree, such as a crack, hole or crevice, and in the one or other it pushes a germ-tube from one or both cells, for it consists of two, and the hypha (*f*) or hyphæ (*g*) find access to the tissues between the bark and wood, there always being a niche around the circumference of a wound.

The tree does its best to cover the wound by which the fungus germ-tube gains entrance into its tissues and makes extraordinary efforts to extrude the intruding organism. The result is that the latter is grown over and gets firmly seated in the soft cellular tissues spreading year by year, until it girdles the branches, and then comes the end. It is a bad case, but there are plenty similar in orchards, yea, and in gardens. The scale has covered the bark more or less with excreta, and on that was the saprophytic fungus called black mould, Fumago vagans, shown at *Z*, enlarged 134 diameters. There was also some lichen and moss. All the overgrowths may be destroyed by the caustic application before mentioned.

As special applications for the canker fungus, after cutting off and burning any twigs or branches wholly or nearly girdled, wash every part with a solution of sulphate of iron, 1 lb. to a gallon of water, applying with a brush; or spray with a solution of sulphate of copper, 1 lb. to 25 gallons of water, using as much quicklime as sulphate of copper, so as to get a protective coating of carbonate without interfering with the immediate action of the sulphate on the fungus. This will certainly destroy the conidial form, and even young perithecia, and, sinking into the cracks, do something to affect the mycelium, besides killing lichenous and mossy growths. These applications must be made whilst the trees are quite dormant, two being best—one as soon as the leaves are all down, and the second just before the buds commence swelling.

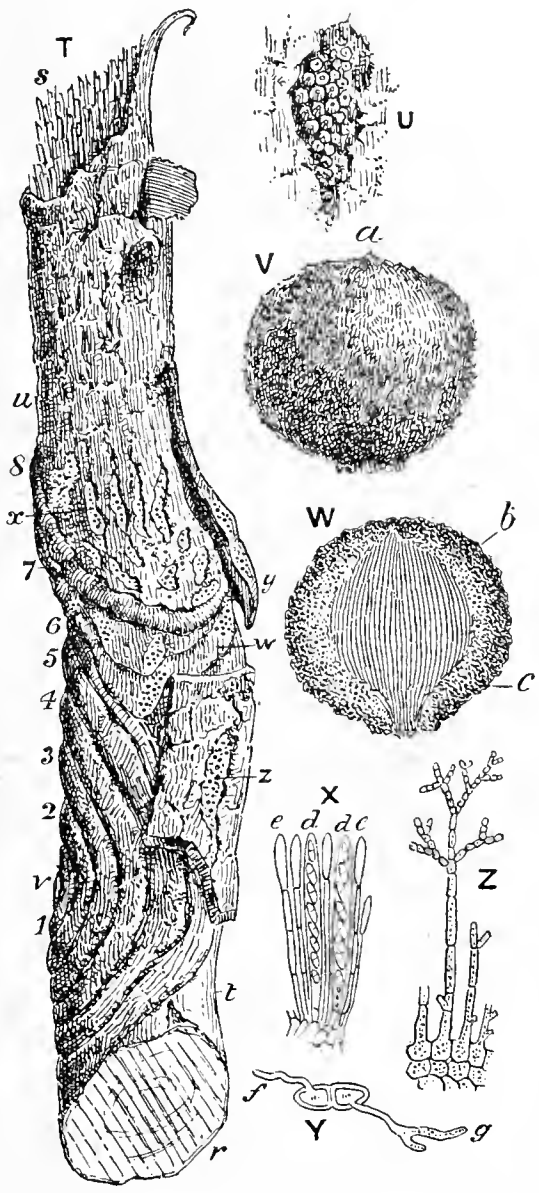

FIG. 44.—CANKER FUNGUS ON APPLE.

References:—*T*, part branch of Apple tree, showing: *r*, sawn off end—sounduess of wood; *s*, broken off end; *t*, bark off; *u*, bark on, living, but dried; 1—6, rings corresponding to advance of fungus hyphæ; 7 and 8, fungus and host in final "struggle for existence;" *v*, point of attack by fungus by germ tube from spore; *w*, outgrowths—pustules of fungus on two-year-old bark; *x*, ditto on nine-year-old bark; *y*, ditto on inner bark of splinter of bark; *z*, patch of perithecia (fruits of fungus) on old bark adhering to scar. *U*, cluster of perithecia (fruits) in crack of bark (enlarged 4 diameters). *V*, perithecium of fungus (magnified 67 times); *a*, nipple, ultimately depressed. *W*, section of perithecium; *b*, external granular coat; *c*, gelatinous nucleus. *X*, fructification of fungus; *d*, cylindrical asci, containing spores; *e*, paraphyses (enlarged 134 diameters) = Nectria ditissima. *Y*, spore (magnified 334 times) = fungus in embryo; *f*, germ-tube or hypha; *g*, hyphæ (branched thread) = mycelial hyphæ. *Z*, black mould growing on excreta of scale (enlarged 134 diameters) = Fumago vagans.

As dressing for the wounds, there is nothing better than a clay plaster, tenacious clay being dried and pounded into powder, then made into a putty with soluble petroleum, easily made by dissolving 1¼ lb. of softsoap by boiling in a gallon of water, and when boiling, but removed from the fire, adding a pint of petroleum, stirring briskly till amalgamated. The wounds may first be brushed out with the soluble petroleum, or preferably sulphate of copper solution, 1 oz. to 1½ gallon of water, and then the composition forced in, having the stopping level with the wound. The petroleum sinks into the wood, gets at the mycelium of the fungus, and kills all it reaches. Mr. Kruse was the first to record the beneficent action of petroleum on canker-fungus in Apple trees, and in the *Journal of Horticulture*, whilst Mr. Allan, Gunton Park, Norwich, recorded the value of the soluble petroleum and clay composition. This encourages the growth of new bark over the wounds by annual rings in the directly opposite way that the fungus takes it off.

Against both scale and fungus spraying at the middle of May, again in ten days, and a third time early in June answers remarkably well with the petroleum emulsion given above, diluting the whole (5 quarts, or thereabouts) to 10 gallons by adding the requisite amount of hot, soft water, and using at a temperature of 90° to 100° when the sun is off the trees. This—1 in 70—petroleum spraying, answers well against all insects unfixed by their beaks in the plant tissues, and

does speedy execution on red spider, also on most epiphytal parasitic fungi, such as mildew, even preventing spores pushing germ-tubes into the tissues of their hosts.—G. ABBEY.

[The publication of this article, which we suspect no other gardener than Mr. Abbey could have written, has been deferred till the time is approaching for the fall of the leaf and the dressing of trees for the subjugation of their enemies.]

CRICKET ST. THOMAS.

LYING somewhat out of the beaten track of horticultural travel, this really very lovely place is about four miles from the small station known as Chard Junction, on the South-Western system, and being on an elevation has commanding views, chiefly of the county of Dorset, in the direction of Weymouth and the sea coast, and has immediately beneath its front the broad and beautiful valley of the Axe, stream or river, which so largely divides Somerset from Dorset. Mr. Crook of Forde Abbey recently drove me over to see this estate, where I found the gardener to be Mr. Lyon, once so well known when at Sundridge Park, Chislehurst, who has since his frequent visits to South Kensington, when both a successful exhibitor and member of the Fruit Committee, become rather greyer, yet seems to be in the full vigour of manhood.

Cricket St. Thomas, though such a singularly beautiful place, for the fine undulations of the park, the noble groups or individual trees, the beautiful as well as luxuriant greenery of the pasture, and the general contour of the place and gardens, with the lovely views beyond, arouse one's enthusiasm—is, all the same, in an unfortunate position. Long the home of the Hood family, the present head of which is the aged Lord Bridport, it is now in the market for private sale, and may shortly pass into the hands of one or other of our rich traders, who are fast becoming the real aristocracy of the kingdom. The old order changeth, is as true of estates as of men, and we see now in every direction the ancestral homes of the landed gentry passing into the hands of the newer rich trader, who, if he will carry into his new sphere liberal ideas, liberal expenditure, a real love for gardening and rural life, and will seek to make the lives of the people about him prosperous and happy, will indeed play a great part in bringing back to these fine old estates much that will be heartily welcomed.

Knowing how largely at Cricket the gardeners' labours had for several years been devoted to the production of fruit and vegetables for market sale, the house having been for a long time unoccupied, I was not prepared to see the pleasure grounds so admirably kept, or the kitchen gardens and houses so capitally utilised. Certainly both gardener and garden merit liberal expenditure, for the best has been done to deserve it.

The house is not a large one, but seems particularly adapted to furnish comfort. The natural prompting is to wish for so fine and so commanding a site a noble mansion. But huge mansions become to so many families great white elephants, in course of time, that it may be well all the same to suppress the desire. The present one is flanked on each side by bold lofty glass corridors, that seem to materially enlarge it, and behind the southern one is a large conservatory. Within the northern corridor I noticed some remarkable plants of the yellow Cassia corymbosa. These were trained to trellises 6 feet wide and 15 feet in height. There were four in number, and they covered the walls between the lofty windows of the room inside. They were planted in stout wood boxes 6 feet long and 2 feet wide, and were literally from top to bottom masses of bloom and foliage. Strong growing scarlet Pelargoniums were carried up and intermixed with the Cassias, and the front of the boxes were faced with a few dwarf ones. These boxes and plants are removed, shortened back, and stood at the back of a lofty Camellia house during the winter. Close by there is the fine climbing Souvenir de la Malmaison Rose previously referred to, and just beyond a grand white Datura suaveolens, forty years old, having a tall huge stem and gigantic head.

On a broad border beneath these yellow Callas are planted out, having been there three years. They had thrown up numerous stout leaf growths, and when in flower present a big bunch of leaves and spathes. On the front broad pilasters supporting the fronts of the corridors are trained various Fuchsias, growths being also carried along the tops of the windows horizontally. They are close trained to the masonry, and were literally masses of bloom. Amongst them were the fine old varieties Marie Cornellissen, Venus de Mediei, Rose of Castile, and others. These presented a very unusual feature in conservatory decoration. Arundo conspicua variegata is very fine and effective for its luxuriant growth here; so, too, in another corridor, is the beautiful Solanum jasminoides. One plant put out at the base of the back wall, others at the upper part, fully 40 feet length, and blooming most profusely. This is indeed a lovely house climber. Camellias are in grand form; so, too, are Roses, as previously mentioned.

A big plant of Climbing Niphetos Rose seems to have been at Cricket before the variety was put into commerce. The old Cloth of Gold, referred to recently, with its marvellous stem, Mr. Lyon mentions, seems to bloom only in the spring; but the flowers are of the most brilliant yellow, quite eclipsing the well-known Marechal Niel. Climbing Devoniensis is also very aged here. In the conservatory the roof is hung with Tacsonia Van Volxemi, blooming in rich profusion. A more beautiful conservatory roof climber than this, and one that gives less trouble to keep clean, does not exist. Apart from their splendid and picturesque situation and surroundings, the pleasure grounds are rich in fine trees, and one, having an historical and somewhat pathetic interest, is a Willow growing beside a spring that bubbles out from the hillside, grown from a cutting taken from the famous Willow beside Napoleon's former tomb at St. Helena.

Though the houses and kitchen gardens have to produce market material, they are well kept and utilised. Grapes, Peaches, Figs, Plums, Tomatoes, Cucumbers, Melons, are all well grown, and so are vegetables. There was a big breadth of the true Ashleaf Kidney, of which some lifted showed a fine sample, and very true to character. This first early Potato is in great favour in the West, where its yellow flesh and nutty flavour is fully recognised. My notes were few, and I write chiefly from memory, but I may hope to see Cricket St. Thomas some day yet under happier auspices, when with a wealthy and liberal owner it may be seen in all that high perfection in gardening the place so richly merits.—A. D.

NOTES FROM IRELAND.

UNTIL recently the general outlook, so far as the staple food products were concerned, was decidedly gloomy, and he would be a bold prophet indeed who would say, even upon the strength of ten days' fine weather generally prevailing over the island, that any great things are promised on the credit side. However, a continuance of the blessing lately vouchsafed was much to be desired, but unfortunately a return has been made to the old order of things, and, judging by meteorological observations from over a wide area, the relapse may prove to be more than a temporary one.

Respecting the harvest our press reports are somewhat conflicting, emanating perhaps from those who are inclined to take extreme views. To say that the harvest, which at least appears to be of fair average in the comparatively early districts of Dublin and its environs, was saved without damage would be saying too much, but undoubtedly a spell of fine weather raised the tone from one of despondency to one of hopefulness, even to that of congratulation, with those who can now say, "All is safely gathered in," irrespective of quality or quantity. That such is not universal is well understood by those who know the wide range of climatic conditions between the eastern and western seaboards, and in the latter, where the whole course of operations is necessarily later, anxiety must not only continue, but increase.

So far as concerns the Potato crop, and that appears to be the chief concern; and one may here remark, what has been more than once remarked by those well versed in Irish political economy, that it is a matter for regret so much dependence is still placed upon it, the prospect is bad. So far, indeed, is the dreaded blight in evidence, that reports from some places show no prospect, total failure being the result of an abnormally early visitation of the foe, which during the whole month of August ravaged some of the more remote localities unchecked. This, of course, means disaster, which so far is localised to certain areas. Never before has the value of spraying been so much in evidence, and possibly the evil will entail some good by attention being forced to the combative process. The remarkable rapidity with which the common foe has marched upon us this year shows the vital necessity of prompt action. Those who are interested in the question might study the value of spraying; might from the present standpoint seriously inquire whether it can honestly claim all the merits that have been showered upon it. If results are satisfactory—convincing, and in my opinion deduced more from observation, I will allow, than from experience, they are, why temporise, one may reasonably ask, with so subtle a foe any longer?

As a cure the virtues of spraying are, I believe, practically nil, but as a preventive so much proof has been adduced of its efficacy that but little doubt need remain upon that point. In this is the whole gist of the question; a question of such importance to the poorer population on this side the Channel, and one, too, which the United Kingdom can neither wisely nor humanely ignore, that one is led to speak strongly upon it, and ask for pity's sake why some urgent measures are not taken to cope with the common enemy. Non-interference in this case appears to be not only a bad policy, but, what is worse, no policy at all. One would scarcely dare venture in these pages to broach even political economy, that is, so far as politics themselves pertain to it, but the matter is one of far too deep concern to allow any little feeling of that kind to preclude it; and sooner or later those who take up the responsibility of the commonwealth will have to face this question, and not only face it, but grapple with it. Much has been done, we admit, to publicly impress the matter; chiefly, if not solely, in the way of good advice. Good advice costs nothing, and such cheap commodities, if appreciated, are seldom availed of.

"Ten shillings and costs" if my dog goes without a muzzle; something else and costs if my baby is not vaccinated; no admittance from an infected port when cholera morbus is on the march; but for Phytophora infestans, which threatens to take a nation in the jaws of famine, which works its ravages unchecked by legislation, and floats in the water-charged atmosphere unrestricted, nothing—nothing; or, at least, that is what the few half-hearted measures practically amount to. I am quite certain these crude expressions on a subject of vital importance, which these brief notes have drifted into, could by a few polished shafts, driven by abler pens, be shattered, but it would be far more to the purpose if the powers that be adopted a decisive policy. Compulsory measures? Even so. "Desperate diseases require desperate remedies," and who shall say that rabies, small-pox, or cholera morbus are more dreaded foes generally than Phytophora infestans is, to Ireland in particular.—K., *Dublin.*

National Chrysanthemum Society.

The General Committee of this Society held a meeting on Monday last at Anderton's Hotel, Fleet Street, Mr. T. W. Sanders occupying the chair. After the usual preliminary business had been disposed of the Secretary read a list of awards of silver-gilt, silver, and bronze medals that were awarded at the recent exhibition at the Royal Aquarium. He then submitted a rough draft financial statement up to date, which was considered satisfactory in every respect. The place and date of the annual dinner were next discussed, and a Sub-Committee, consisting of Messrs. Bevan, Ballantine, and Berridge, was appointed to carry out the details incident thereto.

Some new members were then elected, and the North Canterbury Chrysanthemum Club of New Zealand was admitted in affiliation. Mr. Gordon reported for the benefit of those interested in early flowering varieties that a collection worthy of a visit was at present in flower at the Chiswick Gardens of the R.H.S., and would be worth seeing any time during a fortnight.

In the foreign department Mr. Harman Payne called attention to the forthcoming show and conference at Orleans under the auspices of the French National Society, the executive of which had expressed a wish to see some representatives of the English Society present. Mr. Payne promised to give all further information necessary if it was ultimately arranged for such an interchange of good feeling between the sister societies to take place. A vote of thanks to the Chairman brought the proceedings to a close.

Feeding Chrysanthemums.

Now that the time has arrived for supplying the wants of Chrysanthemums in the shape of manures and other stimulants, I venture to pen a few methods by which the plants may be invigorated. In the first place, no plants should receive artificial or liquid manures until the pots are well filled with roots, as this kind of feeding is not intended to make, nor will it ever succeed in making, rootless plants strong. Feeding such examples mostly has the opposite effect of killing the plants outright. Even when in good health some kinds will not succeed under the periodical use of artificial manures, which can be administered to strong growers without danger when properly applied. The weak rooters may be easily discerned by watching the plants when watering. Many kinds will be still quite moist when the strong feeders are quite ready for water.

Those enthusiasts who pot early in order to get strong plants, thinking of defeating their neighbours (though this early potting is not always the safest), will require to use weak stimulants by the beginning of August. A butt or barrel of some kind should be in readiness. Nothing is better at that time than fresh cow manure and soot. The former should be placed in a wicker hamper with a lid, so that it may be tied down to keep all litter from floating about the receptacle. The soot should be put into a bag and tied loosely; about a peck is sufficient for a paraffin cask full of water, also the same quantity of cow manure, which should be taken out and replaced with fresh every week or so, according to the quantity of water used. The soot will last a fortnight, and will then require to be replaced by a fresh supply. I mention paraffin casks, as these are frequently used for the purpose, after being burned out to cleanse them. Soft water should be used in all cases if procurable. When watering dilute the liquid to the colour of pale brandy, using it twice a week at the commencement. After three weeks the plants will benefit if they are watered alternately with the mixture. I have used horse manure with marked success in the same way, but it is best not to begin with it till September has arrived, not using it more than twice a week. Many of the Incurved kinds thrive immensely when fed judiciously with horse manure, especially the Queens and the Tecks.

When September has arrived feeding in earnest must begin to get the best results. We are now using the drainings of the stables, piggeries, and cowhouses, diluted to the strength mentioned above, or about a 2-gallon watering-can of the liquid to 30 gallons of clear water. We water alternately with this and clear water, giving a change once a week of Clay's or Pearson's chemical manure, using a pint to 30 gallons of water. This change, I should mention, is in the place of clear water, not interfering with the other feeding. Blood is often used, which can be readily obtained in towns or large villages by applying to a butcher. This should be placed in a tub, as before recommended, the soot bag being also added. One pint of this added to 2 gallons of water is sufficient, using it twice a week. I am afraid to recommend this to growers who have their plants close to the dwelling, as the scent from this fertiliser is not all that could be desired. Nevertheless, the finest foliage I have ever seen on the Chrysanthemum was on plants fed with bullock's blood and soot.

Where the cow manure is used throughout the season some other stimulant will be required after the middle of September. We change the diet by giving a dose of guano, one week Clay's, the next a change with Pearson's. Ours is mixed in the water at the same rate as before mentioned. I may here say that Pearson's manure is grand for keeping colour in the foliage, which is essential in all cases.

For small collections grown by amateurs these manures may be applied dry on the surface of the soil; a dessert-spoonful to a 9 or 10-inch pot will be ample. Where large bushes are grown for cutting in large pots they will need more support than a plant that has three or four blooms to open. Much may be done to benefit the plants by top-dressings. These are especially recommended where it may be difficult to obtain the ingredients recommended above. Those who keep a fowl run would find the manure from the roost a good fertiliser. Before being used it should be thoroughly dried, in order that it may be broken into powder, and be thoroughly incorporated with the soil, using about a peck and a half to a moderate sized wheelbarrow load. If this cannot be had, where rabbits are kept in hutches the manure may be saved from them, and it will answer a similar purpose, using the same quantity as of fowl manure. Sheep manure may be also employed in the same form. Clay's fertiliser is also recommendable, using a 6-inch potful to a bushel of soil. The pots should be filled not later than the 1st of September. In all cases a little soot should be used in the mixture—say half a 6-inch potful to a bushel of soil. Watering should be done with a rose for ten days at least after the top-dressing.

We practise this system, using liquids as before stated, but only with plants grown to produce specimen or exhibition blooms. Where large pots are used the plants will not require so much artificial manuring. When potting a knowledge of the kinds is necessary with regard to their constitution, always giving the strongest growers the largest pots, as some kinds will produce as good flowers in an 8-inch pot as others in 10 or 11-inch pots. Feeding should cease when the flowers are half expanded.—An Old Grower.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—September 21st, 1897.

The Hall on Tuesday presented a singularly gay appearance, almost the whole of the tables being quite full; indeed there was packing observed occasionally. The vast majority of the exhibits were for the inspection of the Floral Committee, Dahlias being in very great force. Orchids were not at all numerous, and fruit and vegetables were very little staged. Probably the exhibitors of fruit are reserving themselves for the Crystal Palace next week.

Fruit Committee.—Present: P. Crowley, Esq. (in the chair); with Rev. W. Wilks, and Messrs. G. Bunyard, G. W. Cummins, W. Iggulden, J. Willard, J. H. Veitch, G. Norman, R. Fife, F. Q. Lane, G. T. Miles, G. Reynolds, W. J. Empson, G. Woodward, W. Bates, W. Farr, A. Dean, J. Smith, G. Willard, and J. Wright.

Mr. W. A. Bishop, The Gardens, Westley Hall, sent again some of his seedling Melons—namely Westley Defiance, over-ripe; Dr. Lionel Burrell, soft in the centre, hard at the rind; and Westley Hybrid, not of high quality, and passed.

Peach Late Devonian was sent by Messrs. Veitch & Son, Exeter. This variety was certificated in 1894. The tree is pronounced very hardy and a good bearer; flavour of the fruit is good, and the certificate was confirmed.

Mr. G. Bloxham sent from Brickhill Manor a fine bunch of Bloxham Seedling Grape, cut from a Vine in a pot. It is a greenish white Grape, with rather small roundish berries, having a very tough skin; flesh rather firm, juicy, sweet, with a pleasant flavour. If the berries will keep till March the variety may prove useful.

Mr. G. Woodward sent from Barham Court two dishes of Beurré Mortillet Pear, one from a tree established on Williams' Bon Chrêtien, the other on Doyenné du Comice. The latter were decidedly the larger and better. This is a promising early market Pear, and is said to be better from trees in the open than against walls. A cultural commendation was granted for these fine fruits.

Mr. Empson, gardener to Mrs. Wingfield, arranged quite a trophy of Onions in upwards of a dozen admirably grown varieties, of which Excelsior and Ailsa Craig appeared to be the finest (silver Knightian medal). Mr. W. Kemp, The Gunyah, Barnes, sent a collection of Melons and Cucumbers, and a vote of thanks was accorded.

The Veitchian Fruit Prizes for Flavour.—There was excellent competition with the following results:—*Apples.*—First, Mr. G. Wythes, Syon, with Ribston Pippin. Second, Col. Coleman, Reigate (Mr. King, gardener), with Worcester Pearmain. *Pears.*—First, Mr. C. Herrin, Dropmore, with Souvenir du Congrès. Second, Mr. Wythes, with Autumn Nelis.

Floral Committee.—Present: W. Marshall, Esq., (in the chair); with Messrs. H. B. May, C. T. Druery, R. Dean, J. H. Fitt, G. Stevens, J. F. McLeod, J. Jennings, T. Peed, R. B. Lowe, C. Jeffries, J. D. Pawle, D. B. Crane, E. Beckett, G. Paul, J. W. Barr, and J. Fraser.

A charming display of Roses was made by Messrs. W. Paul & Son, Waltham Cross. The flowers were of very good form, and served as an illustration of the varieties particularly adapted to an autumn display. Especially conspicuous were Queen Mab, Corinna, Camoens, Madame Pierre Cochet, Marie Van Houtte, Enchantress, Mrs. John Laing, and Empress Alexandra of Russia, each of which was shown in considerable quantities. Miscellaneous foliage plants were splendidly staged by Messrs. J. Laing & Sons, Forest Hill. The group comprised Crotons, Palms, and Dracænas, all well grown, and in excellent colour. Messrs. J. Peed & Son, Norwood, had a stand of a very similar nature.

Messrs. J. Veitch & Sons, Ltd., Chelsea, arranged a stand of herbaceous plants, in which large bunches of Michaelmas Daisies were

very noticeable. Amongst them were observed A. candidus, A. novi-belgi Apollo, A. amellus bessarabicus, A. Shorti, and A. acris. Other plants represented were Helianthus rigidus Miss Mellish, Rudbeckia nitida, Helianthus Soleil d'Or, Tritoma hybrida, and Anemone japonica in variety. Messrs. F. Sander & Co., St. Albans, sent handsome pieces of Physalis Franchetti. Several varieties of Chrysanthemums came from Mr. W. J. Godfrey, Exmouth. Lady Esther Smith, Madame Gustave Henry, Barbara Forbes, Miss Emily Silsbury, W. R. Prince, and Milano were the best. Messrs. W. Cutbush & Son, Highgate, showed a few Malmaison Carnations, with handsome fruiting sprays of Phytolacca decandra.

The exhibit of hardy herbaceous and hardy Cyclamens from Messrs. Paul & Son, Old Nurseries, Cheshunt, was a very handsome one. There were Asters ericoides, Clio, acris, bessarabicus, novi-belgi Purity, novæ-angliæ pulchellus, Senecio pulcher, Sanguisorba canadensis, Helianthus rigidus Miss Mellish, Coreopsis lanceolata, Anemone japonica, perennial Phloxes, Gladiolus, Rudbeckias and others. Mr. E. F. Such, Maidenhead, sent a good collection of early flowering Chrysanthemums; while Mr. G. Wythes, gardener to Earl Percy, Syon House, Brentford, arranged a group of splendidly flowered plants of Chrysanthemum Lady Mary Fitzwygram and Lilium Harrisi. Mr. H. B. May, Upper Edmonton, sent fine plants of the brilliant Salvia splendens grandiflora, as did Mr. J. Hudson, gardener to Leopold de Rothschild, Esq., Gunnersbury House, Acton. Mr. J. Witty, Nunhead Cemetery, sent a handsome group of Chrysanthemums interspersed with Ferns. The flowers were of capital quality both in respect of size and colour.

Mr. S. Mortimer, Farnham, Surrey, produced a very bright and attractive exhibit, comprising a good selection of Cactus Pompons, Show and Fancy varieties; Starfish, Harry Stredwick, Gloriosa, Eastern Queen, and J. E. Frewer were most conspicuous in the Cactus section, the Shows and Fancies being exceedingly bright and fresh. Jas. Vick, John Hickling, Majestic, Wm. Powell, Mrs. Saunders, and T. W. Girdlestone were well represented.

From Mr. C. Turner, Slough, came a very pleasing exhibit of Cactus and Pompon Dahlias. The former were effectively exhibited in baskets with their own foliage and Maidenhair Fern. Miss Annie Jones, Starfish, Mrs. W. Noble, Chas. Woodbridge, Iona, Fusilier, and Beatrice were exceptionally well shown. Mr. J. Green, Dereham, had a very good display of his novelties, exhibited on this occasion in a far more pleasing manner than at a former show this season; Norfolk Hero, Green's Gem, Midnight Sun, Mr. Moore, and Crimson King were well shown, all of them being quite distinct and of true Cactus type.

Messrs. J. Cheal & Sons, Crawley, exhibited Cactus, Pompon, and single Dahlias, the whole exhibit forming a very fine display. The Cactus section predominated, and contained some very fine sprays. The most notable were King of Siam, Starfish, Cycle, Harry Stredwick, Chas. Woodbridge, Fusilier, Mrs. John Goddard (a grand novelty), Miss Finch, and Mrs. Wilson Noble. The single section was very fresh, The Bride, Miss Glasscock, Victoria, Amos Perry, and Alba Perfecta being especially deserving of mention. Messrs. Keynes, Williams & Co. had a stand of Cactus varieties. Keynes' White (a variety of true form) was well represented; Cycle, Bridesmaid, Starfish, and Arachne were very attractive.

Messrs. J. Burrell & Co., Cambridge, exhibited Gladioli in their well-known style, staging a very large collection, the whole forming a fine exhibit. Atlas, Rayon d'Or, Formosa, Meyerbeer, Orphée, Baroness Burdett Coutts, Hetty Dean, Matador, and Mikado were most conspicuous. The same firm also exhibited fine stands of Cactus and Pompon Dahlias, the former fully maintaining the standard so well sustained throughout the season. Chas. Woodbridge, Falka, Casilda, H. Stredwick, Fantasy, and Regulus were in grand form. Mr. G. Humphries, Chippenham, also exhibited Dahlias, the Show, Fancy, and Cactus sections being well represented. Mr. J. T. West, Brentwood, staged a large and representative collection of Dahlias. The Cactus section contained some novelties of sterling merit. Island Queen, Oaklands, W. J. Frost, True Friend, and Eileen Palliser were very distinct and conspicuous.

An additional feature to the grand display of Dahlias exhibited on this occasion came from Messrs. Jones & Sons, Shrewsbury, who staged a very attractive exhibit to show how the Cactus section can be employed for decorative purposes. Baskets and bonquets were effectively shown, the colours chosen being those that lend themselves readily to this work. Another bright exhibit of Dahlias were staged by Messrs. H. Cannell and Sons, Swanley, the Cactus section predominating. Mrs. H. Cannell, Mrs. F. Fell, Fantasy, The Czar, Austin Cannell, and Cannell's Gem were amongst the best exhibited. Pompons were very bright and distinct, Pauline, Irene, Captain Boyton, Fabio, and Bacchus being most attractive. A group of Dahlias was staged from Leopold de Rothschild, Esq., Gunnersbury House, Acton (gardener, Mr. Hudson), comprising Cactus, single, and single Cactus varieties, the whole forming a very bright display.

FLORAL COMMITTEE AWARDS.—Silver-gilt Flora medal to Messrs. J. Burrell & Co., for Gladioli. Silver-gilt Banksian medal to Messrs. W. Paul & Son for Roses. Silver Flora medals to Messrs. H. Jones, C. Turner, J. Cheal & Sons, S. Mortimer for Dahlias; Mr. J. H. Witty for Chrysanthemums: J. Veitch & Sons, Ltd., for hardy flowers; J. Hudson for Salvias; and G. Wythes for Chrysanthemums. Silver Banksian medals to Messrs. H. B. May and J. Laing & Sons for plants; J. West for Dahlias, and Paul & Son for hardy flowers. Bronze Banksian medals to Messrs. J. Peed & Son for plants; E. Such for Chrysanthemums, and G. Humphries for Dahlias.

CERTIFICATES AND AWARDS OF MERIT.

Apera arundinacea (J. Veitch & Sons).—A most graceful Grass, which grows about 30 inches high. The inflorescence hangs over in a manner that suggests a fountain (first-class certificate).

Cattleya Hardyana Lowæ (H. Low & Co.).—A lovely variety of Hardyana. The sepals and petals are deep rose, and the velvety lip is very intense crimson (award of merit).

Chrysanthemum Mytchett White (M. Russell).—An excellent early flowering reflexed Japanese variety. The colour is pure white (award of merit).

Crassula Cooperi (Paul & Son).—A capital plant for carpet bedding. The colour of the flower is crimson (award of merit).

Dahlia Falka (J. Burrell & Co.).—A Cactus variety. The flowers are crimson maroon (award of merit).

Dahlia Casilda (J. Burrell & Co.).—A pure lemon yellow Cactus of the very best quality (award of merit).

Dahlia Salmon Queen (J. Burrell & Co.).—A lovely coppery apricot variety of the Cactus type (award of merit).

Dahlia Muriel Hobbs (T. Hobbs).—A handsome yellow coloured Show variety (award of merit).

Dahlia Island Queen (J. T. West).—Rich rosy lavender is the colour of this fine Cactus Dahlia (award of merit).

Dahlia Nelly Broomhead (J. T. West).—A Pompon of good quality. The colour is deep mauve (award of merit).

Dahlia Harbinger (H. P. Harris).—A Show Dahlia of fine form. The colour is mauve (award of merit).

Dahlia Keynes' White (Keynes, Williams & Co.). A white Cactus of excellent form (award of merit).

Dahlia Arachne (Keynes, Williams & Co.).—A bright rose and white striped decorative Cactus Dahlia of merit (award of merit).

Dahlia Laverstock Beauty (Keynes, Williams & Co.). — Very deep salmon is the colour of this Cactus Dahlia (award of merit).

Dahlia Mary Service (Keynes, Williams & Co.).—A peculiarly coloured Cactus. The centre is apricot, and the extremities of the petals lake (award of merit).

Dahlia Maluma (C. Turner).—A yellow Pompon of great beauty (award of merit).

Dahlia Green's Gem (J. Green).—A medium sized terra cotta variety of the Cactus type (award of merit).

Dahlia Miss Finch (J. Cheal & Sons).—A superb variety. The colour is deep crimson maroon (award of merit).

Dahlia Mrs. John Goddard (J. Cheal & Sons). A Cactus of fine type. The colour is rich scarlet crimson (award of merit).

Lælia præstans Gatton Park variety (J. Colman).—A charming variety. The sepals and petals a very delicate mauve, and the extremity of the lip deep mauve (first-class certificate).

Lycaste Denningsiana (F. W. Moore).—The petals and sepals of this Orchid are greenish yellow. The handsome lip is a very deep brick red (award of merit).

Miltonia Peetersiana (H. J. Chapman).—This is said to be a natural hybrid between M. spectabilis Morreliana and M. Regnildi. The colour is a peculiar slatey blue (award of merit).

Oncidium papilio (D. M. Grimsdale).—This Orchid is so well known that any description here would be superfluous (award of merit).

Primula obconica fimbriata (T. Lowton).—As the name implies, this is a fimbriated form of the type (award of merit).

Retinospora obtusa sulphurea (J. Veitch & Sons).—A beautiful variety, of which the leaf tips are of a pale yellow colour. The habit is very good (first-class certificate).

Vanda amœna J. O'Brien (L. Linden).—A most peculiarly coloured Orchid. It may be described as a grey, tinged with blue, and profusely spotted with blue at the base. The lip is blue, with purple speckles (award of merit).

WHO SPLICED THE GRAPES?

READERS of the *Journal of Horticulture* seem divided in opinion on the question of who spliced the Grapes, with intent to defraud at the Crystal Palace Show? The carefully written details of "On-looker," to my mind, savour very much of "the clever young assistant" trying to make two wrongs into one right, if possible. "Exhibitor," who seems to have been on the spot at the time of staging, gravely questions "On-looker's" statements, thereby casting a shadow on the "innocent exhibitor," who, others it seems as well as myself, thought surely would have risen to the occasion, if "innocent," and with any regard for an unsullied name.

After closely examining the interesting exhibit I heard a party of gardeners on the spot asking themselves why a method without a precedent should have been adopted—viz., after removing the slip—first prize—writing "Dis.' on the back of the card instead of *Disqualified* on the face of it? Was it in consideration of the prestige or the name, or the "innocence" of the exhibitor? Or was that "clever young assistant" at work again? If so, "Observer" may well remark, "What will he develop into later on?" My employer asked me if the exhibitor would be allowed to show again at the Agri-Horticultural Association's exhibitions?

Such tricks, unless satisfactorily explained, are not only a disgrace to those resorting to them, but cast a reflection on exhibitors and exhibitions generally.—FAIR PLAY.

PEAR GANSEL'S BERGAMOT.

If "Fruitman" will take the trouble to inquire he will find that many good gardeners entertain the opinion that this is one of the best of Pears. It is unquestionably a variety of great excellence, the fruit being of imposing appearance and splendid quality. Some Pears have become so popular that there is a slight danger of the merits of some good old varieties being overlooked. We would not that this were one of them, for where a good position against a wall can be afforded Gansel's Bergamot will occupy it worthily. The following notes on this Pear by the author of the "Fruit Manual" may be appropriately introduced here :—"The tree is a shy bearer during the first period of its growth, but when it becomes aged it produces more abundantly, though the fruit is of smaller size. To increase its fruitfulness, it has been recommended to impregnate the flowers with the pollen of some other variety, such as the Autumn Bergamot. It is generally believed that this variety was raised from seed of the Autumn Bergamot by Lieut.-General Gansel at his seat, Donneland Park, near Colchester, in 1768, and this rests upon a communication to that effect from Mr. David Jebb of Worcester, nephew of General Gansel, to Mr. Williams of Pitmaston. Mr. Lindley says, 'The Bonne Rouge of the French is evidently of the same sort, and the name must have been given it after its having been received from that country.' I am unwilling that any doubt should arise as to this esteemed favourite being a native fruit; but when I find, by the manuscript catalogue of the Brompton Park Nursery, that both the Bonne Rouge and Brocas Bergamot, which are acknowledged synonyms of Gansel's Bergamot, were cultivated there in 1753, I am inclined to doubt the correctness of the above statement, and as this catalogue is the earliest I have been able to procure of that nursery, it is possible that it was growing there at a much earlier period under both of these names. It is a dessert Pear of the highest merit; ripe during October and November. To have this delicious fruit in perfection it is necessary the tree should be planted against a south-east wall." The engraving (fig. 45) represents a fruit of Gansel's Bergamot.

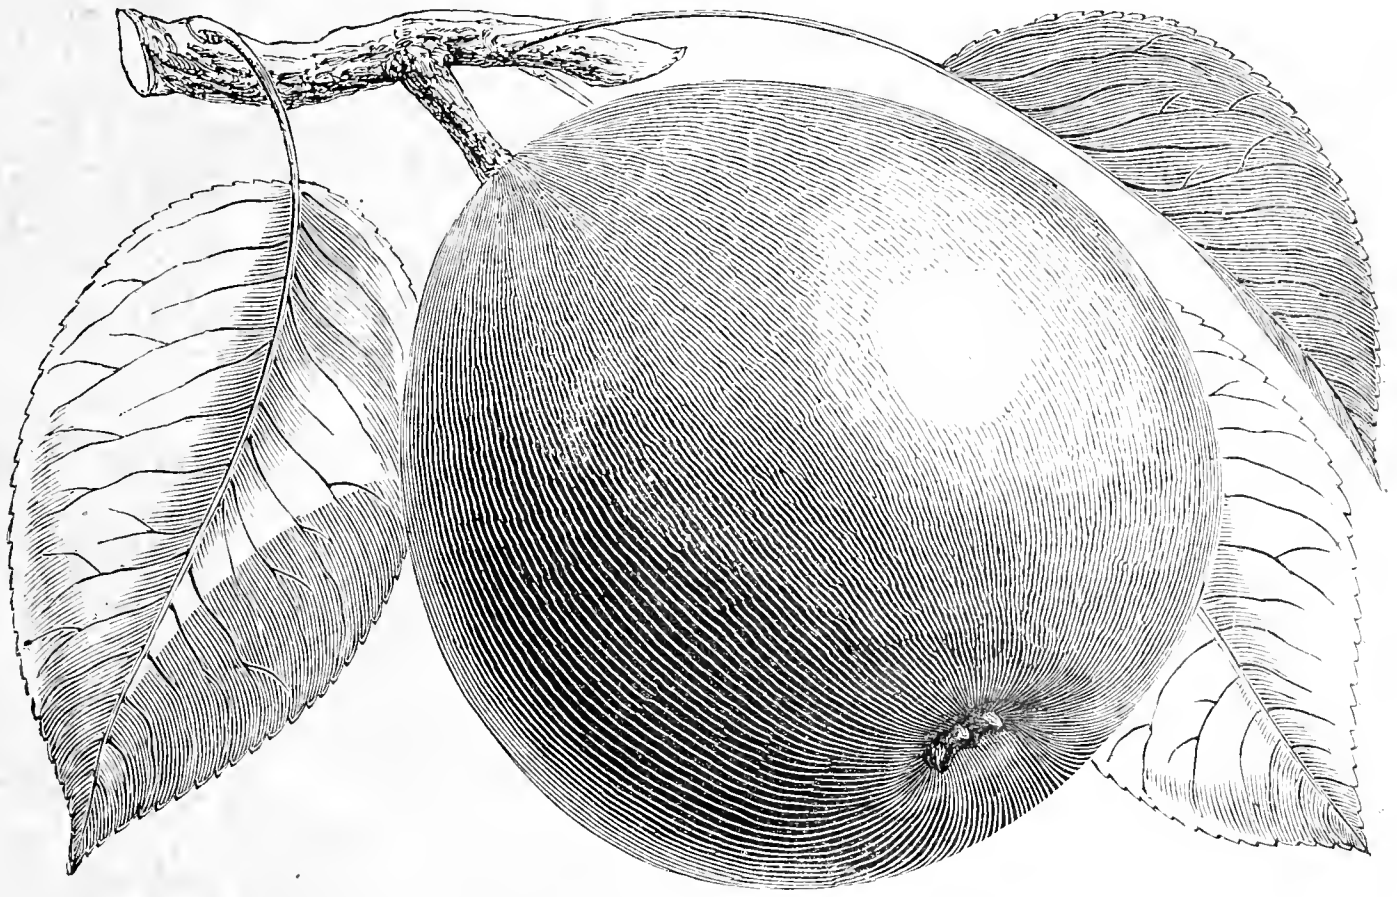

Fig. 45.—Pear Gansel's Bergamot.

NOTES FROM COOMBE WOOD NURSERY.

Calling in here the other day to get a shrub named I was induced to take a walk round, little expecting so late in the season to find anything of special interest. Really there were so many objects of interest that I found it hard to tear myself away. In the lower part of the grounds a pond contains many of Marliac's new and beautiful Nymphæas, with which Mr. Hudson has made us familiar. Around the pond is planted a garden of Bamboos, and there are in it thirty varieties. It will be most interesting in a year or two. Conspicuous, however, are two large plants of the new Pampas Grass, Gynerium Rendatleri, the plumes showing a dense reddish tinge that gives it an attractive appearance.

Hardy Heaths.

These are a remarkable feature, the variety is so great, and so many display such beauty. On the morning of my visit, Erica vulgaris alba had been hard cut to furnish hundreds of sprigs of white Heather for the Drury Lane Theatre management, each first-nighter at the representation of the new play, "White Heather," being with their programmes presented with a sprig. E. vulgaris carnea (pink) and E. v. Alporti (deep red), in full bloom, were also very beautiful. E. polifolia and alba erecta, also atro-purpureum, flowers deep magenta, were blooming profusely. The variety is, however, great, and gives beauty at this season of the year that cannot be over-estimated.

Flowering Shrubs.

A tall, pyramidal plant, having long shoots of pendulous form, laden with small magenta-coloured Pea-like flowers, and forming a very elegant object, was Desmodium pendulifolium. How pretty a shrub was this, thus blooming so profusely, so late in the autumn! Quite an allied shrub was Lespedeza bicolor, also of pendulous habit, having slightly paler flowers. The well-known Rose Acacia, Robinia hispida, though blooming late, was also very gay. It is a beautiful flowering shrub too seldom seen. Perhaps it suffers from the bad name Trec Acacias have with gardeners. What a singularly noble shrub was Clerodendron trichotomum, just then in full bloom! The specimen was about 12 feet in height and 15 feet through at the base. A huge round leafy head covered with small white flowers, and in great abundance, bract-like seed vessels of a reddish colour. Each pod later opens and reveals seeds of a deep purple hue. This is a robust growing shrub, and makes a most attractive object.

But the varieties of Hibiscus, of which there were several, attracted special notice. The three best then blooming profusely were H. albus, flowers quite white and large; Bleu Celeste, flowers of an unusually rich blue for such hardy shrubs, and most floriferous and singularly beautiful; H. single Painted Lady, flowers white, with deep maroon blotches at the base of each petal. It is not possible to conceive of any hardy shrub blooming so abundantly or effectively at this time of the year as this Painted Lady does. It is a shrub for universal planting. We may indeed prize, as we well do, the flowers that bloom in the spring; but shrubs that bloom in the autumn, as these do here mentioned, have a value as objects of beauty that cannot be over-estimated.

Roses in Pots.

These were legion, and stood in the open in large pots, or in smaller ones. Teas especially, in the cool houses; there seemed to be enough to satisfy all the kingdom's requirements. How beautiful in the beds were the many garden Roses, especially the Hybrid Chinas and Cluster Roses. In all directions were the plants carrying beautiful flowers. The young Teas in pots seem now to be in great request for spring planting, in preference to risking them outdoors through the winter, or, if preferable, potted, they bloom profusely under glass for a long season. When, as here, it is seen what Roses have developed into, ample evidence is furnished of the great need there is in horticulture for specialists, for it seems impossible for any one person to have a complete knowledge of everything.

Foliage Shrubs.

A very effective shrub was Cornus brachypoda variegata. This had very striking silvery leafage. The Golden Catalpa gave rich leafage and colouration from cut-back stocks, as, indeed, that is the way in gardens to bring out the great beauty of many foliage shrubs. Cornus atropurpureus treated in this way is very effective; so, too, is the Golden Elder. The purple Cornus edged with the golden dwarf Cornus Spathei makes a very effective mass. The Golden Hop tree, Ptelia trifoliata aurea, is very effective. Singularly pretty, as furnishing long shoots clothed with leaves of cream flushed red, was Acer palmatum tricolor. Such shoots would be invaluable for vase decoration. A most attractive Elder, Sambucus plumosus serratifolia aurea, had very large, handsome serrated leafage of a rich colour. Alnus imperialis, giving beautiful cut leafage, and Acer colchicum nigrum very attractive effects when shoots are cut back in the spring. However, there are many shrubs that thus treated prove exceedingly effective.

Foliage Vines.

Of these several attracted attention, but the most striking were two plants of Japanese varieties, Vitis Coignettiæ, having large roundish leaves, and V. flexuosa, having Mulberry-like foliage. These had made strong growths, reaching 18 feet in height, and later, when the foliage assumes a blood red hue, will be most brilliant objects. As these Vines had been planted about two years their capacity to furnish cover for walls or decaying trees was evidenced. Clematis odorata, sweet scented, flowers dark blue, having prominent centres of white anthers, was exceedingly pretty when in full bloom. Such a nursery as that of Coombe Wood, with all its wealth of new and rare trees and shrubs, presents to gardeners so much that is novel that a visit becomes almost entrancing.—A. Kingston.

THE POTATO CROP.

I hear many accounts of the Potato crop this season, more especially from the farmers, who say that the crop is not more than half the weight of last year, and already disease is beginning to make rapid inroads into some varieties. Speaking to one who grows some hundreds of tons to sell in the Liverpool markets, I was informed that coloured Potatoes by no means find a ready sale, and that he had almost ceased to grow them, the prejudice being that they were all considered of a washy nature. Asking how the round varieties went, I was also told that these were not nearly so much in demand, those preferable being the long kidney shape, as Maincrop and Magnum Bonum. This leads me on to give you a short note of Potatoes in our garden.

The early varieties were not an abundant crop, owing to the cutting winds and keen frosts in May, but the best certainly was Harbinger, one of the finest early rounds ready at the same time as the early kidneys. It is short in the top, a fine cropper, and boils like flour. Early Puritan was good in every respect. Her Majesty and Ne Plus Ultra, tried for the first time, are good. They were not in the best position, consequently I had not an opportunity of fully testing them, but their cooking qualities are all right, and they are free from disease. Up to Date is more after the style of Paterson's Victoria, a grand crop of clean tubers, and fully meriting the name given.

The finest of all in the garden has been the splendid new one named Reliance. If one must judge by the extra good results we have had from it we may expect it to be a beat on the good old Magnum, for a heavier crop I never saw. It possesses a sound constitution, is one of the best shaped kidneys for exhibition, having scarcely any eye, no trace of disease, and for table A1. No praise can over-estimate its good qualities. There seems to be a great deterioration in the useful Maincrop, the crop being poor on every hand, farm and garden alike, as far as I can learn, but I do not know if this is so in all parts of the country. Reading Russet and Flourball are two of the best coloured rounds that we have, the latter being a splendid keeper and a capital table variety.—R. P. R., *Liverpool.*

HINTS ON POTTING.

Of all the numerous operations which come within the range of the gardener's art, that of potting and shifting tender plants from one pot to another must be regarded as one of the most important. A volume could be written on it without exhausting its details or exaggerating its importance in its relation to the numerous varieties of plants and fruits now cultivated in pots. If in anything in gardening "practice combined with intelligence" be not necessary, certainly it is not in potting. By potting I do not merely mean the mechanical operation of surrounding the roots of a plant in a pot with soil. A mere machine might possibly be invented to do that.

Not only does every family and genus of plants need different treatment in this respect, but each species and variety requires to be studied, and the potting adjusted to its peculiarities of constitution and growth. The intelligent observation and sound reasoning of the cultivator must be carefully exercised in the performance of this important operation, or high cultivation need not be looked for as a rule. And very much as has the progress of horticulture depended on the observation or notice-taking of practical men, I question if from any other source improved practice in cultivation has resulted so much as it has from the observations and deductions of practitioners at the potting-bench. However the fact can be accounted for, it has come within my knowledge that men who could discourse eloquently on the science of horticulture, and profess to teach the sound principles of all its branches, make a most complete bungle of potting or shifting a plant, and succeed chiefly in violating every principle on which the health of their subjects depends. In very many instances the practitioner has had to navigate his way to success with next to no extraneous aid, and this forcibly applies to the potting of plants.

In most instances pots are a necessary evil. This being the case, it is of paramount importance to mitigate the evil as much as possible. By way of throwing out a few hints calculated to be useful to beginners at the potting-bench—among whom I would include our scientific friends who may try their amateur hands at this operation, by way of relaxation perhaps—I would remark that the first thing to be considered in potting a plant to be placed in a glass house is that in nearly every respect it is being placed under circumstances that are thoroughly artificial. The space for its roots is unnaturally restricted, and contains, comparatively speaking, but a few handfuls of soil, which, along with the roots, is exposed to the drying influence of air, not only on the surface, but at the bottom and sides of the ball as well. This exposes the plant to be constantly and rapidly robbed of the moisture necessary to its existence, and much of the food supplied to it within the compass of its pot. This unnatural loss has as constantly to be made good by large supplies of water artificially supplied to soil in the very artificial position of being in a pot. This state of things has a constant tendency to call into play a host of other evils which have to be carefully obviated in the choice of materials for, and in the operation of, potting. It being necessary to administer copious supplies of water almost daily, and sometimes oftener than once a day, the two most prominent and destructive conditions incident to such a necessity are those of stagnant water and the rapid decomposition of the organic substances in the potting material. To some extent these evils are dependent on each other, and are nearly always in existence at the same time.

Perhaps the draining or crocking of pots may at this era of horticulture be considered too common or too trifling a subject to dilate on with profit to readers. Good cultivators do not regard any point as trifling, and I am content to submit my verdict to the most successful growers when I say that the draining lies at the foundation of successful pot-plant culture, and that it is one which, if not properly performed and adjusted to the nature of individual plants, will thwart the most careful and correct attention to all the other points of culture. Not only so, but I am convinced that the carelessness and unbusinesslike way in which it is performed in many instances warrants that its importance should be made very prominent; and in a long and extensive practice I am now more convinced than ever that more ill-health and disease and death are caused by inefficient drainage of pots than by any other cause, or perhaps all causes put together.

It is not only not so much on the quantity of crocks put into a pot, as on their proper adjustment, that success in carrying off all superfluous water from the soil in a pot depends. A pot half full of crocks may not be so well drained as another may be with only an inch. In all well-ordered gardens where pot plants are grown there should be three or four different sizes of crocks, sizes that may be termed for ordinary purposes, inch, half inch, and quarter-inch crocks, which, in breaking up a mass of crocks, can be easily assorted by using sieves of different sizes. These must be as clean as the pots themselves, and all dust should be separated from them. Speaking generally the largest of them should form three-fourths of the drainage of large pots, and the other fourth, consisting of the second size, should be blended with the smaller, and over all a little dry moss, or a portion of the most fibry of the soil, should be placed. In a moist stove where plants have to be heavily syringed, or in the case of delicate hardwooded plants, a 14 or 16-inch pot should never have less than 3 or 4 inches of drainage thus arranged; while in the case of special and shallow-rooting plants it should be double this amount, or even more, just as the tendency of the plant is found to be surface-rooting. An 11-inch or an 8-inch pot will be sufficiently drained with a lesser depth of crocks in proportion to its size; 2 inches and 1½ being generally sufficient, but always arranged with the same scrupulous care. This rule applies with augmented force to all plants that are plunged, such as Pines, and to plants of delicate constitution, whether they be soft or hardwooded. The concave side of the crock or piece of broken pot should be placed undermost in placing it over the holes in the bottom of the pots, for, if placed the other way, it often fits too closely to the pots to admit of the ready passage of the superfluous water. Thus arranged, the soil used in potting does not get down amongst the crocks and prevent their serving their intended end.

If anyone wants to prove—who has not done so already—that this is a trifling part of plant culture, let him take two Heaths, Azaleas, Camellias, or even a Pine plant, or a Pelargonium, and drain the pot for one of them as above described, and the pot for its fellow by carelessly—a by no means uncommon practice—putting into the bottom of the pot a few large and ungainly pieces of dirty pot or brick, and subject the plants to the same treatment otherwise, and they will be witness to results so diverse that the matter will soon come to be regarded as of paramount importance, and they will not consider that I have insisted on the strict observance of a trifling point of culture. I might almost say that what the foundation is to the structure, the proper draining is to the successful growth of plants in pots.

Only the other day I was engaged in shifting some Azaleas which had their pots properly drained two years since, and on turning them out of their pots the crocks fell from the bottom of their balls as clean as the day they were put in. The roots of these plants were in the most perfect health, ready for increased feeding ground. In the case of others, which had a few large pieces of crocks pitched carelessly into their pots, the passage for water was next to entirely filled up by the soil working down among the crocks to the bottom of the pots. The consequence was that half the ball stuck in the pot, and it was a soured mass of peat, in which the roots had perished, if ever they had entered it at all. Such crocking in conjunction with old unwashed pots is in time certain death to plants, if the evil is not put right.—T. D.

THE YOUNG GARDENERS' DOMAIN.

Apple Cellini.

In a year like the present one, when Apples, generally speaking, are no more than half a crop, it is well to notice those varieties that are constant croppers, of which the above is certainly one of the best I know. It is a conical shaped fruit, of very handsome appearance, and from medium to large in size, coming into use in September and keeping till the end of November. It cooks well, and is sometimes used for dessert, but it is rather acid, and there are generally plenty of good dessert Apples at that time. Cellini appears to do equally well as bush or pyramid. The tree is a small grower, consequently it does not require much room; planting distance would be about 12 feet. Although many varieties in the same gardens have scarcely any fruit on them this season, the one in question requires support, owing to the weight of its crop.—J. L. G.

Spring Bedding.

When the summer plants and autumn rubbish are cleared off a layer of well decayed manure about 2 inches thick is applied to the beds and dug in rather deeply. Treading is then given and the beds smoothed over with a rake. If the grass be wet when planting commences a few pieces of sackcloth or anything available laid down prevents it being made unsightly. For spring bedding we use Wallflowers, Violas, double Daisies, Myosotis, and various kinds of bulbs.

Wallflowers are topped when 5 or 6 inches high to make them dwarf and bushy; they then stand the winter better than tall, lanky plants. If there is any bracken or long straw available a little placed between and around them protects them from the cold cutting winds which often do much injury in winter; also a slight sprinkling on the Hyacinths and Tulips is well worth the trouble involved. Hyacinths are planted about 6 inches apart and 3 inches below the surface, with a little sand around them. The same applies to Tulips. For a succession of bloom of the last named, alternate planting of single and double varieties is advisable. The beauty of the beds is enhanced by planting tender growths of Myosotis, Silene, or a carpeting of Anemone apennina. A bed planted with Scilla sibirica, with an edging of white Daisies, has a charming effect.—Improver.

[Our correspondent may, perhaps, like to know there is room for him to improve in three directions:—1, In composition and writing; 2, in leaving twice the space between the lines of his MS.; and 3, in sending his letters to the address given at the head of the leading article and of the correspondents' column each week.]

Culture of the Grape Vine.

(*Continued from page* 252.)

Compost.—No hard and fast rule can well be laid down for this. On reference being made to any standard work on fruit culture we can obtain guidance, but we cannot take all from a book; our brains and powers of observation must be used to the fullest. Local composition of the soil has much to do with the construction of Vine borders. In some places grand Grapes can be produced from almost the natural soil, which seems to contain the ingredients that are necessary for the sustenance of the Vine. Happy is the gardener in this case.

Take another example. The soil may be bad, almost unfit for Vine culture, yet the owner of the land and vinery will not go to the expense of procuring any other. What troubles and anxieties the gardener has to contend with then. Do as he will, his Grapes are barely presentable. Every detail in the cultivation of the Vine may be carried out to the letter, and yet there is always something lacking. In this case Vine culture is one continual source of worry to the gardener.

I have seen fine Grapes produced from good calcareous (containing lime) turfy loam, the top 4 or 5 inches of an old pasture, the loam being roughly broken up, and old mortar rubble, wood ashes, and soot well mixed with it, according to the discretion of the cultivator, no strict proportions being adhered to. The compost was prepared some time before being required for use, and protected from the action of the weather.

Making Vine Borders.—It is generally advised to let the inside border fill with roots before making the one outside, openings in the wall of the house being bricked up for the time being. Opinions differ on the subject, but I am an advocate for, say, 1½ yard of border for the first year inside, and the same outside the house, adding 1½ yard each succeeding year until the whole space is filled. By this means the Vines are kept in a healthy condition, as the roots are ever ready to take freely to the new compost.

In making the border, cover the drainage with reversed turves; these will keep it clear for a long time. Place the compost on the turves, making it firm as the work proceeds. Let the outside edges slope somewhat, in order that, when a fresh amount of compost is required, the edges can be lightly pricked up with a small fork, the added compost binding more freely by this means.

Planting.—Some gardeners advise planting the young Vines when in a growing state, these being taken into the house a few days in advance to inure them to the temperature. Other Grape growers allow the Vines to complete their growth for the season, and rest in the pots before planting. It is with the former method I intend dealing. Excavations should be made of ample depth and width for the reception of the balls of soil turned out of the pots, and the roots ought to be carefully disentangled in order that they may take freely to the compost in which they are placed. In planting it is well to lay out as many as possible in layers, with soil between them, taking care not to break any of the roots. The soil must be finely broken up and worked amongst them with the fingers. Plant firmly, and not too deeply, and settle the soil about the roots by affording a good watering.

Keep the Vine straight by means of a stick fastened to the wires, the cane being tied to it. A straight stem will then be produced, which looks better than a crooked one. Allow a sufficient distance in planting, so that when the stem is developed it will not come in contact with the hot-water pipes. It will be found necessary to resort to the syringe and shading for some short time after planting the Vines, to prevent flagging. As regards distance, for permanent Vines, from 4 to 5 feet asunder is advisable.—Semper.

Anthuriums.

This large genus of stove and greenhouse plants is remarkable for the peculiar inflorescence and often noble leaves. Fibry peat, loam, sphagnum, broken crocks, or charcoal, and silver sand, form the most suitable compost.

In preparing the peat, it should be broken up into small lumps, and then have most of the earthy matter knocked out of it by giving it a few raps with a stick, or by shaking it about in a sieve. To this, after so treated, add about one-fourth its bulk of sphagnum and about half its bulk of fibrous loam, and just a sprinkling of fresh broken crocks, or small pieces of charcoal and sharp silver sand. In placing them in the pots, which must be well drained, carefully spread out the roots and work the mixture among them, keeping the plants well up, so that when finished they stand clear above the rim of the pot at least 2 inches or 3 inches, and form a kind of mound or hillock. They must then be kept freely syringed or watered, and placed in a moist atmosphere, where they can enjoy a temperature ranging between 60° and 70°, or a few degrees lower for the less tender species.

Raising plants from seed requires patience. About a year elapses from the time the flowers are fertilised, which should be done artificially before the seed ripens, and often another to get up plants. Sow as soon as ripe in shallow, well-drained pans or pots, filled with the potting mixture, and cover slightly, in a close, moist, propagating case, where a temperature of from 75° to 85° is maintained, or they may be covered with bell-glasses. The principal thing is to keep the air about them constantly humid, and the material in which they are sown in a uniformly moist condition; if this is done, the young seedlings will make their appearance in due course. When these are of sufficient size to handle, they should be pricked off in the same sort of compost, and be kept close and moist till they get a start, after which, gradually inure them to more air. January is the best month of the year wherein to propagate these plants by division. This is done by carefully turning them out of their pots and shaking out what soil they have amongst their roots, which must be tenderly dealt with, so as not to bruise or injure them. This done, they may then be pulled apart, and must have a copious supply of water at all times, although, of course, much less during the winter than spring and summer months. There is no season of the year when they can be handled for any purpose with less risk or check than January. A moderate moist stove heat is advisable for them generally.—W. M., *Wexham Park.*

HARDY FRUIT GARDEN.

Wall Trees.—*Shortening Secondary Shoots.*—Apples, Pears, and Plums trained on walls, and which had their foreright growths shortened earlier than others, will most probably have formed fresh young shoots from the upper buds of the restricted growths. These ought, therefore, to be pruned back to the first leaf, when that has attained a fair size.

Finally Stopping Growths.—New extension wood or shoots produced after this period are of little practical use, and when such growths indicate a decided tendency to continue growth, especially Peaches, Nectarines, and Apricots, the shoots may be stopped by cutting off the points. The effect of this will be to assist the ripening process of the current year's shoots, and cause the sap to concentrate itself in the buds of the lower and more mature portion of such growths, gradually forming them into fruit buds, interspersed with wood buds.

Removing Superfluous Shoots.—When the fruit has been gathered, Peach, Nectarine, and Apricot trees should receive careful examination, so as to dispense with all shoots that have borne fruit. Cut them out close to the origin of reserved shoots destined for the future bearing. This treatment relieves the trees considerably, and directs the energy towards the young wood. An additional benefit derived, which is of importance, is the more thorough exposure of shoots to light and air, insuring a well-ripened condition.

Securing Growths.—In preference to allowing shoots to lay about in various directions, temporarily lay them in towards the wall or trellis in the direction intended for final training. They will thus receive the advantages of warmth of wall.

Cleansing.—During the time the leaves remain green, assimilation of food from the roots, and that taken in from the air, goes on. This, of course, is beneficial; but if red spider infest the trees, the work the leaves perform is obstructed. Hence it is desirable to give the trees a dressing of insecticide immediately the fruit has been gathered, and occasionally syringe the foliage afterwards, until the leaves change colour,

Gathering Fruit.—Carefully continue the gathering of Apples and Pears, also Plums and late Peaches.

Apples.—All the earliest varieties of Apples ought now to be off the trees. Varieties which may now be gathered include Lord Suffield, Cellini, Domino, Potts' Seedling, Jolly Beggar, Cherry Apple or Siberian Crab, Yellow Ingestrie, Worcester Pearmain, and Wellington.

Pears.—Of Pears, gather Williams' Bon Chrêtien, which is rather late this season, and the crop poor; Madame Treyve, Brockworth Park, Hessle, Autumn Nelis, Flemish Beauty, Fertility, Autumn Bergamot, and Crassane.

Plums.—The following varieties are now ripe or approaching maturity—Jefferson, Pond's Seedling, Washington, Autumn Compôte, Coe's Golden Drop. Gather the choicest fruits by the stalk. Ripe or ripening fruits left on the trees should be well protected.

Applying Liquid Manure to Fruit Trees.—The autumn months are very suitable for rendering assistance to fruit trees which require additional nourishment at the roots. Such applications will largely benefit weakly trees. They will also improve the soil where a succession of crops has impoverished it.

State of the Soil.—Liquid manure can in numerous instances be applied freely at this season, inasmuch as the soil in open quarters has become suitably moist from frequent rains. In all positions, however, this may not be the case. Wall trees are frequently an exception. The soil near walls may have become so dry from long-continued drought and the extra demands of trees that much rain is necessary to moisten it.

Moist Soil Essential.—The soil must be made comparatively moist before stimulating and sustaining liquid manure can be applied with benefit. Therefore, when the soil is very dry, give copious soakings of clear water prior to the manure.

Suitable Liquid.—The drainings from farmyard manure are the most generally useful, for they contain most, if not all, the essential constituents of plant food. Household slops diluted with soapsuds may be employed. The contents of cesspools are most valuable for fruit trees when diluted down to a safe strength with clear water. Stable or cowshed drainings, either alone or in mixture, form useful nourishment, none of which ought ever to be wasted where well established or old fruit trees exist. The soluble ingredients of the latter will then be better retained by the soil and readily available for absorption by the roots.

Method of Application.—As the roots of trees extend as far as the branches, any applications intended to reach the root must cover the area of ground to that distance. Where roots are not very near the surface loosen the soil with a fork, so that the water or liquid manure may be more readily admitted. A few deep holes made with a crowbar is an excellent way of quickly moistening the lower strata. This is not a plan to be generally recommended for trees having the bulk of their roots near the surface, such as Apples on Paradise, and Pears on Quince stocks. Apples on Crab stocks and Pears on Pear stocks have roots which penetrate deeper in the soil, and there would be less danger of damaging the fibres.

FRUIT FORCING.

Melons.—*In Houses.*—As the days are shortening, the nights being relatively cold, even white frost occurring in the morning, and the moisture increases, it is necessary to exercise care and judgment in watering, never doing it unnecessarily; but the latest plants with the fruit swelling must not be allowed to become so dry at the roots as to prejudice the foliage. Maintain moderate moisture by damping the floors, walls, and sides of the bed every morning and at closing time, earthing-up the roots as required; but late plants require less soil to grow in than the mid-season plants. Remove all superfluous growths as they appear, and maintain a temperature of 65° to 70° at night, 5° less on cold nights, 70° to 75° by day, up to 85° or 90° with sun. Keep the bottom heat at about 80°. Fruit ripening will be better for a little extra fire heat and a circulation of air constantly. A dry condition at the roots, but not so as to cause the foliage to flag, accelerates the ripening process and enhances the quality of the fruit.

In Pits and Frames.—In those heated solely by fermenting materials no water will be required after this time unless the soil is dry and the foliage becomes limp, which it must not be allowed to do. Any water supplied should be so as not to wet the foliage or even the surface of the bed more than can be helped. Keep the frames well lined, admitting a little air constantly, which, with the fruit raised well above the surface of the bed, will do much to accelerate the ripening, prevent decay, and impart flavour. Any fruit it is wished to keep for a time should be cut when changing with a good portion of stem, and be kept in a dry, airy room; or if wanted ripe at once it may be placed in a warm, airy house on a shelf in the full sun. Melons ripen better there than in frames or pits devoid of fire heat.

Peaches and Nectarines.—*Early Forced Trees.*—We would again urge the necessity of attention to these trees as soon as the leaves are all down, following the instructions given on September 9th (page 252), as the procedure strikes at the root of pests passing over from year to year, especially red spider and scale, and gives the trees the advantage of thorough rest, with opportunity of pushing fresh roots, thus being well prepared for a start when the proper time arrives.

Early Forced Trees in Pots.—Where new trees have to be bought, the earliest placed orders generally secure the best trees, and they can have their requirements attended to in respect of top-dressing without delay. This is very important, as those disturbed late at the roots do not carry the buds well, nor is the start and setting of the fruit nearly so satisfactory as when this has been anticipated by timely attention to secure it in the late summer.

Second Early Forced Trees.—These, often the first in many places, they being started at the new year, will have shed their leaves, or be in that condition shortly, and should be attended to in pruning, cleansing the house, dressing the trees, and top-dressing the border according to instructions already referred to, as this gives them better advantages than putting off everything until the last moment, when neither house nor trees can be properly cleansed, and much after trouble in respect of pests is the consequence.

Trees Ripening the Fruit in July.—The trees will now be approaching the resting period, and the foliage becoming sere. Supply them with water so as to keep the soil moistened through to the drainage, but if the roof-lights have been removed, the trees being in a condition to allow of its being done in August or early in this month, they can remain off until the time of starting arrives, and the soil will get well moistened by the autumnal rains, and frost and snow have an invigorating effect on the trees, as well as having a good result on the enemies that beset them. If the wood is not ripe it is not wise to expose the trees to heavy rains and snow.

Assuming the wood is firm and the buds plumped, it is advisable to remove the roof-lights, with a view to insure complete rest and the thorough moistening of the border. When the trees are very strong it is not desirable to withdraw the top-lights, and if the growth is complete (barring a few sappy laterals) and the wood not ripening kindly, form a trench about one-third the height of the trees from the stem, and detach all roots down to the drainage, leaving the trench open for ten days to a fortnight, when it may be filled firmly. Young trees only require this, but older trees that have the wood very strong may be root-pruned, and the roots wholly or partially lifted before the leaves have fallen. This requires to be done carefully, as very vigorous trees have roots corresponding to the branches—long, strong, and few; hence a severe check must follow severe root-pruning, and the after-growth be more or less prejudiced, if, indeed, the trees are not seriously imperilled in life and limb. Judgment in such cases must be exercised, it being good policy to cut only a few strong roots in one year, and then follow on with the others another, so that, having got the roots comparatively near the stem and plenty of fibres, complete lifting can be carried out without any danger, but much benefit as regards health and cropping. Some trees have straight down roots, which must be got at and severed before there can be any improvement in the trees' growth and bearing.

In the case of weakly trees remove the old soil from over and amongst the roots, supplying fresh strong loam, with an addition of calcareous matter where the loam is not of that nature, making it firm, and following with a good soaking, the drainage being good, of liquid manure, afterwards top-dressing with some approved fertiliser. The manurial matter will get more or less diffused through the surface soil during the winter, and possibly adventitious roots be pushed into it before starting, as we have sometimes noticed, and certainly when the trees move. Cut out weak wood and branches.

Trees Ripening the Fruit in August and Early September.—The wood that has borne fruit and not required for extension must be cut out, leaving no more than can be freely exposed to light and air. Cleanse the foliage of dust and red spider by water directed with force from a syringe or garden engine, and repeat occasionally. If there is scale syringe with water at a temperature of 140° to 160°, and for red spider and brown aphis, the latter of which sometimes attacks the younger parts of the wood in autumn, promptly apply an insecticide, the aphis being best destroyed with diluted tobacco juice. There must not be any lack of moisture at the roots, therefore apply water to the inside border as necessary, to prevent their becoming too dry. Afford abundant ventilation, and if the wood is not ripening well keep the house rather warm by day and throw the ventilators open at night; but a warm, close, moist atmosphere must be avoided, as that would be more injurious than otherwise. In other respects the house cannot be too freely ventilated.

Late Trees.—When the fruit from the earlier ripening varieties has been gathered the trees will need to have the shoots thinned where too crowded, and those which have borne fruit and not required for extension can be cut out to a successional shoot at the base. This, with free ventilation and gentle fire heat in dull weather in cold localities, and the wood strong, will assist in ripening the growth, which is of primary importance as regards next year's crop. It is also important to keep them free from insects, hence syringing forcibly, or using an insecticide after the fruit has been cleared off individual trees, must be attended to, always without wetting trees with fruit ripening. Avoid a too dry condition of the border, and expose the fruit of very late varieties to the sun and light as much as possible. The trees must not lack moisture, and yet a rather drier condition at the roots is advisable whilst the fruit is ripening. Mealiness often arises from insufficient supplies of water during the swelling period rather than from dryness during the ripening process, but at no time is dryness to the extent of affecting the foliage desirable. Some soft netting will be useful to save any fallen fruits, but it must be looped up in small pockets to prevent the fruit bruising each other. With an examination of the fruit every morning by an experienced person, the ripe fruit being removed, there is little occasion for the netting, especially with the very late varieties. The fruit is better gathered before it is dead ripe, and kept in a light airy fruit room until thoroughly matured.

The late Peaches are very noble in appearance, and of excellent quality when well done. Prince of Wales, very little seen, is a magnificent fruit when grown under glass and in warm soils, but it is not satisfactory against walls and in heavy soils. Gladstone, a similar fruit, does splendidly in a late house, it being very large and of first rate quality when well fed during growth. For looks Princess of Wales is, perhaps, the grandest of all late summer Peaches, attaining a large size and assuming fine colour under favouring circumstances, and Late Admirable also, has both size and quality to recommend it, also

Walburton Admirable. Sea Eagle sometimes colours grandly, and even when pale has a very pleasing appearance, its size and good qualities rendering it very desirable. Golden Eagle has both size, golden colour, and good quality to recommend it, while Comet proves very acceptable early in October.

PLANT HOUSES.

Allamandas.—The growth of plants that have been used in the conservatory has nearly ceased. If these are removed at once where the night temperature ranges to 60° they will soon start into growth again, and continue to yield flowers until Christmas. Fully expose them to the sun, and supply stimulants liberally if the pots are full of roots. Plants that flowered early may be induced to rest by placing them in a temperature of 55°, where water can be gradually withheld. Do not ripen them prematurely, or the wood will eventually shrivel instead of remaining firm and plump. Two months' rest is ample for these plants, and if rested now they may be pruned and started again early in December.

Clerodendron fallax.—Select two or three of the earliest plants and allow them to flower where the atmosphere is moderately dry and a circulation of air can be provided daily, seed will then be produced freely. When well grown this Clerodendron is very ornamental in the stove or intermediate structures during the next two months. Insert plenty of cuttings of C. fragrans, they will be useful for flowering in small pots early in the year. The cuttings should be inserted singly in thumb pots, and when well rooted place them into 3-inch pots. They flower freely when confined at their roots. If given liberal root room they grow too luxuriantly and fail to flower satisfactorily.

Ixoras.—Select a number of growing shoots that are moderately soft, and insert them in sandy soil in 2-inch pots. These will be useful for decorative purposes in spring, and carry one fine truss each. Young plants that are well rooted and growing freely may be placed into 4-inch pots. Press the soil firmly, and grow the plants on a shelf close to the glass in a warm moist atmosphere. They will make greater progress if gentle bottom heat can be provided for a time. Fully expose them to the sun. Large plants that have become woody through being confined at their roots are flowering freely the second time, and others will not be long before they yield a supply of trusses for cutting. Young plants growing into specimens should have the points of any shoots removed that are taking the lead. Keep the plants free from mealy bug by examining them frequently, and syringe at once with a solution of tobacco water, or fumigate the plants with tobacco smoke if thrips become established upon them.

Aralias.—Plants of A. Veitchi, A. Veitchi gracillima, A. leptophylla, and others that are large enough for table decoration may be placed in a temperature of 50° to 55°. They will remain in good condition, and growth will be very slow. In brisk heat they run up quickly, and soon become useless. Plants that have been raised from portions of stem and are growing freely may be placed into 4-inch pots, and grown in brisk heat. These do well in loam, sand, and one-seventh of manure. Where there is a plentiful supply of fine peat a little may be mixed with the loam.

Crotons.—Plants that are highly coloured and large enough for table and other forms of decoration should be prevented making further growth. Fully expose them to the sun, and place them where the night temperature can be kept at 55°. Admit air daily, and gradually increase it. This prepares the plants for room decoration better than when removed from a warm moist atmosphere. Plants that are fully exposed to the sun, highly coloured, and their pots full of roots, are liable to be attacked by red spider. Be careful the soil does not become dry at the roots of the plants, and syringe them liberally. The plants are greatly benefited by being syringed once or twice weekly with soot water perfectly clear. Assist plants in a backward condition by keeping the house warm and close, closing the ventilators early, so as to run up the temperature considerably in the afternoon. Insert in small pots all highly coloured side shoots that have been produced by plants from which the tops were removed some time ago.

Pancratiums.—The earliest of these are growing freely, and as they cease flowering must be kept close, moist, and shaded from the sun, with abundance of water and occasional stimulants. Any plants that need larger pots may be attended to at once in a compost of loam, sand, and one-seventh of decayed manure, a little charcoal may be added. It is not advisable to break up the plants in their present stage of growth. The check would be too serious, and prevent the plants making good growth afterwards. Plants that need division should be left as they are until February, or just preceding growth.

Vincas.—Pinch the shoots of plants in 5-inch pots for the last time; they will be useful in the stove during the dreary months of winter. The shoots are also useful for cutting; in warm rooms they will continue to develop their flowers for a long time after they have been severed from the plant. Cuttings may be inserted in small pots for early spring flowering. Large plants that have ceased flowering may be placed in a moderately dry atmosphere where the temperature ranges about 55°, and gradually withhold water.

Dracæna gracilis.—This is probably the most useful of all Dracænas for room decoration. It will stand in almost any position for a long time. Large plants may be removed to the greenhouse. In this position avoid cold draughts striking upon the plants. Those that have grown too large may have their heads removed and rooted in 4-inch pots. Those raised from heads are very useful for single vases, while those from the stem are the most serviceable for table decoration. They are lighter through the foliage being only about half the width of those that have grown strongly.

THE BEE-KEEPER.

Utilisation of Spare Bees.

In apiaries where straw skeps largely predominate I fear it is still the fashion (for one cannot call it by any other name) to destroy the bees when taking the honey in the autumn. Why this should be the case it is difficult to say, as in most districts there are always bee-keepers who are ready to lend a helping hand to their less fortunate brethren in the craft. Still the fact must be recognised that the sulphur pit is not a thing of the past, but that many stocks of bees are annually destroyed throughout the country, which if their lives had been spared by taking a little trouble in the simple process of driving, they would have been of great assistance in strengthening weak colonies of bees in the same apiary.

The above remarks have been called forth after visiting an apiary which six weeks ago consisted of twenty-three stocks, all with the exception of one being in straw skeps. All that remained at the time of my visit were ten skeps and one frame hive; a dozen stocks had been suffocated; the dead bees still remained in heaps where they had been shaken from the hives. On my remonstrating with the bee-keeper on the cruelty and the loss he had sustained by destroying the bees, he remarked, "But of what use were the bees to me? As I have now as many stocks as I require, and I do not want more bees, I thought the easiest way to get rid of them so as to obtain the honey was to place them over the sulphur pit."

On inquiry I found he had been much troubled with swarms, and it was chiefly the first swarms that had been taken. He allowed me to examine several of his old stocks, which, owing to the swarming mania, were short of bees and also of stores. Had the bees been driven, and added to the colonies that were kept for stock, they would have strengthened them very considerably. I showed him how this could be done, and have no doubt in the future the lives of the condemned bees will be saved.

Uniting Driven Bees to Straw Skeps.

As there are doubtless many bee-keepers throughout the country situated similar to the above, a few words on this subject may be of benefit to them. It is useless attempting to unite driven bees with those already existing in straw skeps by simply shaking them into the hive and sprinkling them with flour or thin syrup; it would mean instant death; but by making both colonies of bees homeless for the time being they will unite without the loss of a single bee. First drive the bees from the condemned stock into an empty skep. If the queen is aged catch her as she runs up, and destroy her. If the operator is not an adept at finding the queen it does not matter, as the bees will soon settle the dispute between themselves. As soon as the majority of the bees have run up into the empty skep remove it, and repeat the same operation with the stock hive intended to be kept.

When a large proportion of them have joined the other driven bees remove the skep, and shake the bees well up together, at the same time sprinkling them with flour from a dredger; also sprinkle any bees that remain on the combs of the hive intended to be kept. Place the latter on its original stand, prop up the entrance 2 or 3 inches, so that the bees may have ready access, shake the two stocks of driven bees down in front of the hive, a puff or two of smoke will cause them to hasten into the hive, and in a few minutes the bees will have clustered between the combs a united and happy family. No fighting will take place, and if properly carried out the lives of all the bees will be saved. Proceed with the others on the same line, and the bee-keeper will have the consolation of knowing he has saved the lives of his bees.

In practice it takes up much less time than many imagine. If by chance the hive to which it is intended to introduce the driven bees is somewhat crowded, it will be advisable to place an eke under it for a few weeks, as the bees will soon cluster in a smaller compass as the weather becomes cooler. An eke may be made by cutting off 3 or 4 inches from the bottom of an old skep, or something similar.

Feeding Driven Bees in Skeps.

It will be apparent to all that it is useless preserving the lives of the bees unless an extra supply of food is provided for them. In straw skeps it is not so readily done as in frame hives, as has been shown in previous notes. When a rapid feeder is used a strong colony may be supplied with 28 lbs. of thick syrup in forty-eight hours or less. If a straw skep is flat-topped, in which form they should always be made, it is much easier to feed them from the top than when they are made otherwise, and is safer than to feed from the bottom, as the latter encourages robbing, which it is advisable to avoid as much as possible.

It is necessary to avoid an escape of heat from the hive, and for this reason, if no other, a bottle feeder answers the purpose admirably.

Obtain a large-mouthed bottle, holding about a quart of syrup, over the mouth tie a piece of muslin, or something of open texture, fasten it tightly round the neck with a piece of string. The hole at the top of the skep must first be covered with a piece of perforated zinc, on the top of which the inverted bottle must be placed, and the whole covered up warm. It is an advantage if the syrup is given warm at this season. Refill the feeder as often as is necessary, and the chances are that stocks of bees treated in the above manner will come out strong and healthy, and will throw off early swarms the following spring.—An English Bee-keeper.

TO CORRESPONDENTS

*** All correspondence relating to editorial matters should, until further notice, be directed to "The Editor," **8, Rose Hill Road, Wandsworth, London, S.W.**, and **NOT** to Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Carnations Diseased (*C. A.*).—The "grass' is infested by a mild form of rust fungus (Uromyces caryophillinus). The parasite readily yields to dilute Bordeaux mixture, mentioned in reply to "R. S.," or dusting with the advertised fungicides in powder, such as anti-blight, fostite, and other similar preparations; but some growers prefer permanganate of potash, 1 oz. to a gallon of water, spraying on the foliage lightly, just coating them with a thin film of the solution. If those preventives had been applied much sooner, the plants would not be in the condition they are now.

Removing "Yew" Tree (*J. W., York*).—If the spray sent was from the tree it is an Elm, the Winged or Wahoo (Ulmus alata), a very desirable North American species. By cutting off the head at 1½ yard from the ground, you will to some extent check the growth of the roots, and prevent the further lifting of the asphalte pavement, but it will not kill them, and though not such a keen suckering species as the English Elm, it would probably throw up suckers, also push growths from the part of bole left. We should clear the tree away bodily as soon as the leaves have fallen, say in November, and then bore holes with an augur in the direction of each root of the tree from the cut-off part, filling each with a saturated solution of saltpetre, or fill with the article and pour in sufficient water to cover the nitre, then plug the hole tightly with a wood plug, and you may not be troubled with suckers, at least we found the plan answer almost as well as arsenic, this being a very dangerous substance to use and the other quite safe.

Diseased Chrysanthemum Leaves (*C. S.*).—The magnificent, large, thick, leathery, deep green leaves (barring brown spots) are seriously infested by the rust fungus (Trichobasis Artimisæ), the pustules being much larger than commonly found on Chrysanthemums. This shows the fungus not to attack the plants because unhealthy and poverty stricken, for the leaves afford evidence of high-class culture. Quite a cloud of dust fell on the microscopic slide, thousands of spores on the square inch of surface. Every one will grow if it has a chance in presence of such abundance of food as your plants afford. The point is to prevent the spores germinating. This ought to have been done at least a month ago by dusting the plants on the under side of the leaves with a 10 per cent. sulphate of copper preparation in powder, such as anti-blight or fostite, using a bellows apparatus, and blowing upwards. Now lay the plants on their sides, and spray or syringe with a solution of sulphide of potassium, 1 oz. to 3 gallons of water, doing it outside, as the sulphide smells nastily and discolours paint. Do it well; let the leaves get nearly dry, then syringe with clear water if you like, but that is not necessary for anything but appearance. There are numbers of pustules not broken through the epidermis; these will not be killed by the sulphide solution, therefore repeat in the course of a few days. If more readily obtainable use permanganate of potassium, 1 oz. to a gallon of water, spraying on the under side of the leaves. This sinks into the pustules. It is only necessary to coat the under side of the leaves with the finest possible film. Do something, and at once, for never was seen a finer harvest of spores, and that means a corresponding broad-casting of seed for another crop.

Burning Sulphur in Vinery (*Waltham*).—We do not burn sulphur in houses of any kind devoted to the cultivation of useful plants. After pruning the Vines and removing the rough bark, we wash the rods carefully with a brush, using a solution of sulphate of iron, 1 lb. to 1½ gallon of water. It acts against both fungi and insects, especially mites (red spider); or 4 ozs. caustic soda (97 per cent.), and 4 ozs. commercial potash (pearlash), dissolved in 3 gallons of water, applying when the Vines are dormant. This will kill the very fine-coloured hybernating mites, commonly called "eggs" of red spider, and these got rid of there will be none to continue the breeding the following year, unless, of course, they come from elsewhere.

Young Vines Killed by Eelworm (*Cross*).—The four young Vines, at least the one you have sent us, have been attacked by eelworm, as you suspected, hence asked, "Would eelworm enter the Vine roots?" The answer is No; the species only attacks the plants on the root stems just above the roots, thus making sure of a plentiful supply of nourishment for itself and offspring. It is the root-stem eelworm (Tylenchus obtusus), and the most prevalent form attacking Cucumbers in this country. In answer to your other question, "Is there any disease in stem or roots?" The stem has its bark entirely destroyed all round just within the soil. The roots are perfectly healthy, a mass of fibres, such as any grower would be pleased to see, and the cane itself stout, short jointed, hard in wood, and small in pith. The eelworm was probably introduced in the "rank" top 6 inches of old Cucumber soil. We should give at once a dressing of best chalk lime, freshly burned, 1¼ cwt. per rod, slaking with the smallest amount of water necessary to cause the lumps to fall to a fine, apparently dry, powder, spreading evenly, and pointing in the soil as far as can be done without injury to the roots, and not deeper than 6 inches, taking small spits so as to incorporate well. Watering the Vines with soluble phenyle, 1 part in 96 parts of water, will do no harm, and may do good, using it on the affected stems. If you like to earth up the other three so-called "dead" Vines you will get roots from above the girdled parts, and also test the potency of the preparation mentioned for killing eelworm. We may, perhaps, give an illustration of the case.

Diseased Pears (*R. S.*).—The Pears are attacked by brown rot fungus (Monilia fructigena), now in the mycelial hyphæ stage, which you may easily see on cutting a fruit in halves. The brown irregular marking corresponds to the cells or parts destroyed by the parasite, and the fungal threads are readily distinguished by a lens enlarging 250 diameters, as pushing their way in the intercellular spaces of the living cells of the fruit. Later on the fruit ordinarily becomes covered with a white mould in beautiful rings. This is the conidial condition or Monilia fructigena form; but the affected fruit sometimes only remains brown, even drying and shrivelling, yet small black bodies form in the fruit, and these carry the disease over from year to year. The common form of continuance is, however, by perennial mycelia in the wood of the tree affected, commonly referred to as "canker" on young shoots. We mention this, for if there are any such on your tree they must be cut out to sound wood, dressing the cuts with gas tar, but not allowing this on the young wood. Then root-prune the tree as soon as the leaves commence falling, operating carefully, so as not to cause a very severe check, on one side of the tree if roots are strong this autumn, following with the other side the next. This, and supplying fresh compost, with the burning of affected fruits, we have found effectual from a cultural point of view, supplemented by spraying with a dilute Bordeaux mixture, 1 lb. of copper sulphate and 1 lb. of lime to 12½ gallons of water (1) just before the blossoms open; (2) as soon as the fruit is well formed; (3) a fortnight afterwards; (4) again in another fortnight. This prevents the fungus spores taking possession, and thus, paradoxically speaking, goes to the root of the evil at the top of the tree.

Fruit Trees for Walls (*W. B.*).—*Apricots:* Frogmore Early (small), Alberge de Montgamet (small, chiefly used for preserving), New Large Early (large), Hemskerk (large), Kaisha (medium), Peach, Moorpark, St. Ambroise, Powell's Late (the last four large and excellent). *Cherries:* Early Rivers, Belle d'Orleans, Governor Wood, Bigarreau de Schreken, Downton, Black Tartarian, May Duke, Black Eagle, Werder's Early Black Bigarreau, Elton, Bigarreau Napoleon, Reine Hortense, Florence, and Tradescant's Heart. *Figs:* St. John's, Telfer, Brunswick, Brown Turkey, and White Marseilles. *Nectarines:* Early Rivers, Lord Napier, Darwin, Stanwick Elruge, Violet Hâtive, Hardwick's Seedling, Humboldt, Dryden, Pineapple, and Victoria. *Peaches:* Alexander, Early Louise, Hales' Early, Dr. Hogg, Grosse Mignonne, Dymond, Royal George, Bellegarde, Noblesse, Violet Hâtive, Barrington, Princess of Wales, and Walburton Admirable. *Pears:* Doyenné d'Eté, Jargonelle, Williams' Bon Chrêtien, Beurré d'Amanlis, Souvenir du Congrès, Triomphe de Vienne, Beurré Superfin, Louise Bonne of Jersey, Marie Louise, Emile d'Heyst, Doyenné du Comice, Thompson's, Glou Morceau, Passe Colmar, Josephine de Malines, Beurré d'Anjou, Marie Benoist, Winter Nelis, Passe Crassane, Beurré Rance, Doyenné d'Alencon, Bergamotte d'Esperen, and Easter Beurré, with Uvedale's St. Germain for stewing. *Plums:* Dessert—July Green Gage, De Montfort, Denniston's Superb, Jefferson, Purple Gage, Green Gage, Transparent Gage, Rivers' Golden Gage, Coe's Golden Drop, Reine Claude de Bavay, Bryanston Green Gage, and Ickworth Imperatrice. Kitchen—Early Prolific, Czar, Belgian Purple, Large Black Imperial, Prince Engelbert, Victoria, White Magnum Bonum, Diamond, Pond's Seedling, Monarch, Autumn Compôte, and Archduke. A south aspect suits all the fruits, but the most suitable are Apricots, Figs, Nectarines, and Peaches; an east aspect answers for Cherries and Plums, and a west for Pears. Only Morello Cherry does well on a north aspect; but kitchen Plums, especially Victoria, bear fairly, and some Pears; also the May Duke of all Cherries.

Small Bunch of Grapes (*W. B.*).—"What is the matter with the small bunch of Grapes sent, also the remedy, and the name of them?" The answer is, as regards the "matter," (1) badness of colour, (2) imperfect finish, (3) resultant shrivelling, and (4) mould. The berries are very small, streaked, and altogether indifferent. There is no disease to account for the decay of the berries. The remedy can only be found in more liberal treatment in the way of nourishment. You give no particulars about the age of the Vine, nor of the soil and position in which it is established.

Chrysanthemum Leaves Yellow (*Perplexed*).—The shoots and leaves are a beautiful yellow or golden colour, quite as effective for contrast as many plants grown solely for that purpose. There is nothing whatever the matter with their tissues, except the colouring pigment or chlorophyll granules are xanthophyll, but why so we cannot tell; and what is of more consequence we fear the colour is so decisive that the change again to green will be very difficult, especially as the plants have been watered with weak soot water twice a week. This, as you know, gives a dark green colour to plants. We had a similar experience with some plants that were watered with soot from chimneys where wood had been largely burned. We then supplying nitrate of soda instead, a quarter oz. to a gallon of water to begin with, increasing to double strength by degrees; the colour improved, and where begun early enough entirely changed to deep green. This you may try, with an occasional addition of half the amount of sulphate of iron, Sometimes we have found an alternation with sulphate of ammonia assist wonderfully, not using it stronger to begin with than nitrate of soda, supplying about twice a week, always with a watering of clear water between. We do not think the watering has anything to do with the chlorosis or yellowing; it is a matter of nutrition or constituent elements of the soil, or those supplied. The plant is Polygonum sachaliense.

Destructive Grubs in Garden (*Anxious*).—The grubs are the larvæ or caterpillars of the Turnip or Dart moth (Agrotis segetum), commonly called "surface" caterpillars, as they live and feed near the surface of the ground. They do an enormous amount of damage, but variable in infestation. The caterpillars will eat almost anything in the vegetable way, feeding on Cabbage, Carrots, Beet, Leeks, Onions, Lettuce, Turnips, and Spinach. The egg is laid from June to late summer, according as the moths emerge from pupæ, and the caterpillars hatch in about a fortnight, and feed chiefly on parts of plants above ground. As they get older they hide by day and feed at night, in bad weather feeding wholly under ground, and this they carry on during the winter when hatched late. The early ones form cells in the ground and turn to pupæ in the spring, coming out as moths in June onwards. The "grubs" are difficult to get at, but after all hand-picking is the best remedy. A dressing of salt (10 cwt. per acre, 7 lbs. per rod) acts better than anything we have tried, scattering it evenly; but it tells somewhat on the plants, therefore must be kept out of the hearts. For similar reason kainit cannot well be used, otherwise 5 cwt. per acre, 3½ lbs. per rod, clears them off, and you can apply it when the crops are cleared; then it will get at them, and leave potash in the land for future crops. On foul land gas lime (5 tons per acre, 70 lbs. per rod) may be used in autumn, and left on a month or six weeks before digging in. That will clear the soil of the pests.

Names of Fruits.—*Notice.*—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. *In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing.* The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. *They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state.* (*G. O.*).—1, Golden Noble; 2, King of the Pippins; 3, Emperor Alexander; 4, an inferior variety, not worthy of a name; 5, Potts' Seedling; 6, Blenheim Pippin. (*Fruit Foreman*).—1, Kerry Pippin; 2, Reinette de Canada; 3, Lord Suffield; 4, Ribston Pippin. (*B. T. E.*).—1, Beurré d'Aremberg; 2, Beurré Superfin; 3, Williams' Bon Chrêtien. (*P. S. M.*)—1, Alfriston; 2, Maltster; 3, Lewis' Incomparable; 4, Bergamotte Esperen; 5, Beurré Hardy; 6, perfectly hard. (*J. B.*).—1, Worcester Pearmain; 2, Lord Suffield; 3, Lord Grosvenor; 4, Winter Greening; 5, Ribston Pippin; 6, Mère de Ménage. (*W. B.*).—1, Cellini; 2, Cox's Orange Pippin; 3, Hollandury; 4, Borsdörfer; 5, Nonesuch.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*W. J. G.*).—1, Vitis humulifolia; 2, Ulmus campestris var. latifolia. It is a variety of Elm frequently seen in a variegated form, but frequently runs out of colour. (*W. Jinks*).—Asclepias currasavica. (*F. H.*)—1, Aurya latifolia varicgata; 2, Cassia corymbosa; 3, Veronica longifolia subsessilis. (*P. I. J.*).—1, Pyrus sorbus; 2, Cotoncaster frigidus; 3 and 4, withered beyond identification; 5, Pyrus aria. (*Inquirer*).—1, Linaria alpiua; 2, Sedum reflexum; 3, Lysimachia nummularia; 4, Monarda didyma; 5, Galega officinalis; 6, Sedum ibericum. (*A. M. M.*).—Schomburghia Lyonsi.

GOOD NEWS AT LAST.

After years of falling markets we may be excused if we greet any little return of better prices with great acclamation. The difference a few shillings per quarter in the grain crop just turns the scale one way or the other. A rise of a few shillings makes the crop a profitable one; the fall spells disaster in big type.

During these years of depression much stress has been laid on the necessity for feeding more stock instead of cultivating cereals; but some of these wise advisers have not fully considered the question of food for this extra stock. They say in a lordly manner, Lay down more land to permanent pasture, forgetting, or not knowing, that land best calculated for corn growing is not always suitable for grass

or varieties of Clover. They forget also (and this is a sad indiscretion on their part) that they are advising men who are in many cases in money difficulties, or who find the money market decidedly tight. Laying down land to grass means a large present expenditure in suitable seeds; it also means a long waiting time, till those seeds of grass have attained a proper growth—*i.e.*, a growth which will allow of them being mown or grazed without permanent injury. Now, during those years of waiting the rent still goes on, and that rent has to be supplied from some other source, and is often very difficult to find. We do not have land at prairie value here, or, at least, we have not met with it in our parts.

There is not a shadow of doubt but that our good sound English-grown Wheat is more nutritious as an article of diet than the dry white grain we import from foreign parts, and when English Wheat and English flour can be once more grown at a profit to the farmer a good supply will be found somewhere.

Of course, we know that with our best endeavours we cannot produce enough for our teeming population, yet a little encouragement in the matter of price has a wonderfully stimulating effect on the producer. We have seen the introduction of many fine varieties of seed Wheat, bold in berry, upstanding, and of very great fertility, and we have little doubt that our great raisers are yet prepared to do more for us in this line. Beside, too, every year opens up new vistas of promise in the way of tillage. Science comes to our aid, and teaches us how to grow five ears of corn where only four were found before.

Now, at the conclusion of this harvest of 1897, we view the situation with much satisfaction. "Punch" was the first in the field to touch on passing events, actually devotes a large cartoon to agriculture, representing Ceres with an overflowing basket and beaming at the prospect of better prices. May the prices last! Surely the townsfolk who have had cheap bread so long at our expense will not grudge us this little gleam of sunshine in our cloudy sky.

This year we find from statistics just published that the area under Wheat for the United Kingdom has increased by 200,000 acres. This is something substantial, and we are glad to record that the yield is a very fair one. Of course, as there are spots in the sun, there are places where from some cause or other the yield is disappointing, but these places are in the minority. Then, again, too, in the South and East the crops were got in very good condition. Wheat, too, in the North has not suffered so much as might have been expected from the broken weather. It was all so dry to begin with that it took much rain to make any impression whatever. Barley has been the greatest sufferer; bad weather affects the colour, and makes the maltster look shy. Curiously enough, from Wiltshire come accounts of badly damaged Barley, while from Scotland we hear that the greater part of the Wheat was safely housed before the weather broke. This fact rather makes us wonder when the Wiltshire Barley was sown. We have urged and advocated all our lives the necessity of early sowing for Barley, and as the years roll by we see no reason to alter our opinion; on the contrary, as long as we have a breath left we shall still preach the old doctrine.

Last year (1896) the kingdom grew 1,734,118 acres of Wheat; this year the total is 1,938,183 acres, being a little short of the acreage of 1894, but 484,168 acres more than two years ago. This year, too, we stand alone as a nation in having an increased area and good yields, beating especially every continental nation.

It is rather difficult to come to a correct conclusion as to yield, but we think we shall be about the mark when we give 29 bushels per acre as the average.* We think we are not too sanguine, but of course we are open to correction on this point. Last year the estimate was as follows:—

Acres, 1896.	Bushels per acre.
1,731,976	33·63
Acres, 1897.	**Bushels per acre.**
1,938,183	29

* Since writing the above we have seen several well-known agriculturists of Nottinghamshire and Yorkshire, and they are most emphatic in their assertion that the Wheat yield will be found not to exceed 24 bushels per acre. We hope they may be wrong, but they are men on whose judgment we can rely.

Now, then, for the prices for the last few years.

September 1st to August 31st.	Per quarter 480 lbs. s.	d.
1892–3	26	10
1893–4	25	5
1894–5	21	3
1895–6	24	11
1896–7	28	5

This year, since June, there has been a steady rise from 27s. per quarter to 33s. 7d.; indeed, we have seen new White at 38s. 6d. and Red at 36s. Some old White, too, met a market at 41s. Of course, this was a specially good sample. There generally is a rise of price early in harvest before the threshing machine has got fairly to work; but now, although much Wheat has been put on the market, there is still a tendency in prices to harden.

Oats, too, are worth more money, and those people who have good samples of Barley are sure to meet a good trade. There is a feeling, too, abroad that the Potato crop may be more remunerative than of late. That the crop is small there is no doubt, and small crops mean enhanced prices. So far, we must depend upon ourselves in a great measure for the production of this tuber. Germany does send us some occasionally. Let us hope that this year they need all they have grown for home consumption. We do not wish to deprive our Teutonic friends of a single ton.

WORK ON THE HOME FARM.

A beautiful week has rejoiced the hearts of belated harvesters; full advantage has been taken of it, and in most districts the grain is safely under cover. There has been little absolute waste, but much damage to Barley samples, which will be reduced in value if not in bulk.

Fallows are now working well, and we have seen many fields full of little heaps ready for firing. Burning twitch and stubble is supposed to be very wasteful, but by burning we do not lose the potash, and with nitrogen at the present price, we hardly think that rotted twitch is worth the labour of twice carting; at any rate burning is the most expeditious plan, and time is of great value in making the best of fine weather at this season.

Old seeds are ploughing well, and Wheat must go into a capital seed bed. The ploughing must be done at once, so as to get settled and firm before the corn is drilled. Winter Tares should be sown as soon as possible. The land ought to be fairly clean, and well dressed with good decayed manure. This should be well buried with the plough and the seed drilled at once. Thin plants of Clover may be renovated with suitable mixtures, but this should be done without delay. We think there is nothing better than Dwarf Italian Rye Grass for this purpose, at the rate of 3 pecks per acre.

Unless it be for semi-permanent seeds, it is hardly worth while sowing Clovers so late; the risk of non-germination or destruction by severe frost militating much against a profitable result. Second early Potatoes are being rapidly cleared off, and when we hear of 3 acres of good land producing but 5 tons for market, it will be seen that they do not take much moving. Everywhere we hear of crops being but half of what they were last year, 5 tons per acre being quite the top limit. Late kinds are growing again luxuriantly, and will not be ready yet; we hope when they are, hands will be more plentiful than they were last year.

The Irishmen who are not now needed for the corn harvest are sadly missed in the Potato field later on, and a good man would earn quite as much picking Potatoes as he could at forking grain crops.

THE PLEASURES OF FRUIT GROWING.

IN these days of high pressure, keen competition, and profit seeking, there is a danger that the simple pleasures of gardening, apart from the pecuniary aspect, may be to some extent obscured or forgotten. As a recreation, and a means of relieving the mental strain endured by the busy professional man, gardening offers in many directions what few other occupations can yield—namely, healthful exercise, leading to enjoyable results. I am writing as one who has made his calling the study and pleasure of a life, and who has also seen somewhat of other countries than his own, and the conviction has long been formed that there is scarcely another occupation which affords those who engage in it, either for a living or as a recreation, so much real pleasure as gardening. This is equally true if it is taken as a whole, or when a department only is made a special hobby and study. The amateur who has his costly and superb collection of Orchids does not derive more satisfaction from the inspection of his valuable treasures than is enjoyed by the town mechanic with his Auriculas or his Ferns, and the parson's pride in his Roses is equalled by that of many a cottager with his prize vegetables or window plants. Hardy plants, too, have their devotees, and who can gauge the pleasure such flowers have afforded to thousands?

Still there is a department of horticulture to which perhaps fewer amateurs have applied themselves as a hobby, and this is hardy fruit culture. Generally the one absorbing idea when fruit culture is talked about is the pecuniary aspect, but why this should be so exclusively the rule it is difficult to determine. Perhaps with regard to Orchids the prospect of profit is taken into account somewhat, but it is a question that is rarely entertained in regard to any other horticultural hobby to the same extent. There are exceptions, it is true, and it is rather remarkable that in some instances where the commencement of fruit culture as an amusement for leisure hours was entirely free from any serious thoughts of profit, the results have proved even more remunerative than those whose plantations have been started on a presumably commercial basis.

Two notable examples of what amateurs can accomplish in hardy fruit culture, and how much entertainment they can secure from effects that may ultimately prove very profitable, recently came under my notice, and a few descriptive notes may not be devoid of interest to some Journal readers. The first visit was paid to a plantation at Harpenden formed by Spencer Pickering, Esq., F.R.S., a gentleman of considerable eminence in the world of science. In the course of his chemical investigation he met with an accident which for some time endangered his sight, and outdoor exercise became indispensable as a means of restoring his health. Some experience at Rothamsted and familiarity with the great work performed by Sir John Lawes and Sir Henry Gilbert led Mr. Pickering to take an interest in experimental work amongst plants, and the perusal of horticultural literature concentrated his attention upon hardy fruit culture. Attached to Mr. Pickering's residence is an old orchard which has permitted him to indulge his taste to the full in experiments connected with what may be termed tree-surgery, for many of these presented an array of cankered stems and branches that would have been rather appalling if profitable fruit crops had been the only object in view. In some cases the diseased wood has been cut away until only a narrow channel is left for the conveyance of the sap, the wounds have been dressed with tar, hollow places have been filled with cement, and it is astonishing, in many instances, to see the vigorous efforts being made by the trees to heal their wounds by the formation of new tissue.

In some extreme cases the trees have had their larger limbs removed, or they have been beheaded and grafted with strong scions, the majority of which are making vigorous growth, and bid fair to rejuvenate the veterans which have been subjected to many years of bad treatment or neglect. That every one of these experiments is a subject of special interest to the operator can be readily imagined; but they possess an interest beyond that, for they show that there are times when the knife must be freely and boldly used to effect the desired purpose. They also show what vigour there may be left in old trees if they are subjected to the right treatment.

Experiments on old trees were not enough, however, to satisfy Mr. Pickering, and about four years ago he commenced a plantation of young trees away from the old orchard, and this is already giving satisfactory results. The soil is heavy, containing a quantity of stones, but it was thoroughly and deeply worked before laying it out for planting, and a liberal dressing of London stable manure was dug in. About an acre was enclosed by a wooden fence on two sides and an open iron fence on the others. In this space nearly 1000 Apples, Pears, Plums, Damsons, and Cherries were planted together, with 2000 Currants and Gooseberries. The general scheme of the plantation is to have standard Plums as the basis, with dwarf Pears and Apples between them, the intermediate spaces being again utilised for the Currants and Gooseberries, some trained trees occupying a portion of the ground. Taking the trees generally, satisfactory progress has been made, and even in a season of scarcity, like the present, it is gratifying to see vigorous young trees of Cox's Orange, Potts' Seedling, and other useful varieties laden with fine clean fruits. Some of the Pears are similarly well grown and well cropped, conclusive evidence being afforded by all the trees that both soil and treatment have been right.

The Plums are, however, a rather deplorable instance of how even good treatment may fail in producing the desired effect. A mysterious disease has attacked them, and it appears probable that a large percentage of deaths will ere long have to be recorded. This is the more regrettable since the trees started well and have developed good heads, and had, moreover, reached an age when profitable crops might have been expected. The bark seems to die in patches or strips, the altered appearance being plainly evident in most cases; the injury extends both upwards and downwards, affecting the wood as well, until when the circuit of the stem is completed with dead bark and cambium, the fate of the tree is determined. So long as a longitudinal strip of living bark and tissue remains the tree struggles for life, and by careful excision it is possible that some may recover, but in the majority of instances it is hopeless, the leaves lose colour and droop, and the fruit becomes prematurely ripened.

It has been found that a fungoid growth is present in the bark, but whether this is a cause or a result of the disease has not been determined. Frost injury has been assigned as a probable predisposing cause, and some weight is attached to this, but the matter is still under investigation, and no doubt the results will be ultimately brought before the public. Fruit growers have abundance of evils to contend with in the shape of insect pests, but if developed trees that have reached bearing size are liable to be lost in this mysterious manner, for which there is no apparent remedy, the difficulties and prospects of loss will be increased tenfold. This certainly cannot be counted as one of the pleasures of fruit growing, unless the evil can be overcome, when perhaps the satisfaction will in some measure compensate for the loss.

Apart from this disaster there can be no question that the owner of this plantation has derived a considerable degree of pleasure from it in planting, tending, and watching the progress of the trees, far in excess of the expense; yet there has been an appreciable return in fruit crops during the past two years, sufficient to pay a fair interest on the capital expended, and there is every prospect of this return being materially increased, notwithstanding the loss of the Plums.—OBSERVER.

(To be continued.)

NATURAL VERSUS ARTIFICIAL FERTILISERS.

(*Continued from page* 258.)

IN considering the claims of natural manure or organic matter, as essential in successful cultivation of the soil, possibly some readers, learned or semi-learned in the science of manuring, may dissent from some of my conclusions. They may say that "artificial manures effect wonderful results," and ask us, in proof, to look at the produce at exhibitions. Admitted. In the vegetable market nothing can rival the home-grown article, but have artificials alone produced it? Never. "We have grand Grapes." Yes; but look at the Vine borders of loam, the top inch or two of the richest accumulation of organic matter, bones and what not. For what does this organic matter count? Do "artificials" alone grow good Grapes for years without any manure? Look at the fact, turn it over, make sure what there is due to the "natural" and what to the artificial ingredients. This is being done by experiment on collegiate lands and experimental grounds. Even the Rothamsted experiments, conducted on an unparalleled basis, have not set agriculture on its legs. But the scientific and practical investigators and experimenters ever point to the intrinsic value of organic matter.

Grind rock into various degrees of fineness, and in this soil operate with natural and chemical manures separately on growing plants. What is the difference? The natural products contain some available and a certain amount of unavailable plant food, but they also yield acids in decay acting on inorganic material, or the rock, to go along with the nitrogenic matter into the plant in the soil waters. The purely chemical preparations, fit for plant food, do nothing of the sort. Plants fed by them, as in water culture, must have supplies more or less constantly, and are only of use for the time, and as such unreliable or dependent upon something else for the measure of utility. The world is now so replete with organic remains that few soils do not contain at least some to render "artificials," even wholly chemical, useful, but organic matter we *must* have, and experience teaches that it is best supplied in decayed natural or farmyard manure.

Thus far we get at nothing but the necessity of a judicious blending of organic with inorganic substances in "artificial" fertilisers. In some their use does not extend beyond bones, in others fish meal; and in not a few rape meal or native guano. Analysis shows the value of, say, bone ash superphosphate, and nitrate of potash; bone superphosphate, nitrate of soda and muriate of potash; mineral superphosphate (high grade), sulphate of ammonia, and double sulphate of potash and magnesia. In comparison with these fertilisers, analysis of native guano, for instance, is nowhere. That is the chemical test. What is the practical? Ascertain by experiment on a Vine border. Put on so many shillingsworth of native guano, which by chemical test is worth next to nothing, and the same number of shillingsworth of

high-class fertiliser, which by chemical test is good as gold, and note the result—not for one, but several years. The chemically worthless article turns out in practice the most valuable, both as regards weight of crop and the colour and quality of the produce.

Then night soil, according to analysis, is about the poorest manurial substance known. In practice, there is not a better manure for growing Grapes, Onions, and Rhubarb. It is slow, but its effects appear in the green colouring matter of leaves, and the purple, black, and golden amber of fruit. It is good for everything to which it is applied, if given time to show itself in the produce. It must be tempered in some way and reduced, just as blood is made into a dry powder alike for portability and application.

For poverty of analysis stable and farmyard manures come very low; indeed, according to the chemists' standard, there is very little worth having in either. Farmers, unfortunately, let the stamina run off in ditches, and not many gardeners find enough liquid in the tanks to meet their requirements. There is nothing like good "muck." It improves the staple of soils as well as restores what has been taken off in crops—a combination of advantages not possessed by chemically prepared manures. For grass land nothing comes near farmyard manure in value, whether as regards hay, milk, butter, beef, or mutton, and as regards "roots" all the mixtures put on by hand cannot approach it for usefulness. In the garden I have never seen too much of it in the properly decayed form except on Vine borders, where it could not be said to be used, but abused, when not associated with a due apportionment of inorganic matter.

The time is at hand when land will be cleared of crops, and the best time to use stable or farmyard manure is then. All ought to be prepared so that it can be readily spread and turned under. It will not waste in the land or even on it. The rains of winter wash nothing away but the worthless stuff, for the soil has a vice-like grasp on ammonia—holds it until the microbes wake up in the spring, and then the roots of plants reach out their hair-like tongues and sip in the energising diluted essences. Potash in like manner does not run away, it stops along with the ammonia, ready for use in the quickening of vegetation by the sun. Magnesia also remains, as does the phosphoric acid, for the soil lays hold of them and keeps them till wanted by plants, be these weeds or useful crops. The earth, cultivated, is a store-house of good things for plants, only put them in more or less raw and let Nature and "brains" do the rest.

But it may be said the action of old-fashioned manure is slow. When spring comes the ammonia has to be made into nitrite and nitrate. The old gardeners knew that time was required for its action on the soil, and not only knew, but acted, for abroad over the land went the soot, held back during the winter, or out came the Peruvian guano in the spring and quickly moved the crops, outdistancing slugs, and when the flush of these spring dressings were over the microbes kept up the running of nitrogen in the plants. The old gardeners knew of the value of such practice, and in some instances they were amongst the first to lay hold of the valuable scientific facts which chemists brought to public notice; but those gardeners never, and do not even now, let go the sheet anchor, for they still cling to the time-honoured manure heap, the loam of the pasture, and the leaf mould of the woods.

Thus the horticultural ship rides safely because the anchorage is sound, and observant scientists, having been taught by successful workers, now advise the use of fertilisers in the autumn—a practice they once disavowed. Bone manure, even superphosphate (not mineral), with potassic manures (not in nitrate form), are advised to be used in the autumn or very early spring. This is the practical and right way. The old gardeners led the way in using liquid manure in winter (the value of the applications being first made known through these columns) instead of letting it run to waste, and growers of produce for market lose nothing they can obtain in the shape of manure at any time and from any source. Scarcely any material comes amiss, for put on something they must and will, but always with judgment, well knowing the difference between the food that has to be made ready in the soil before it can be appropriated by plants, and that which is quickly available. From such practice and investments they obtain profit, or they would not, and could not, be pursued generation after generation.

Finally, the artificial manure manufacturer, who possesses both practical and scientific knowledge, does the mixing in far different form than formerly. The "flash in the pan" custom has given way to a rational blending of organic with inorganic materials, a quickly acting, and at the same time steadily supporting dietary being provided. Artificial manures have helped wonderfully in horticulture, simply because they have been used as supplementary to sound staple in soils, the judicious use of other substances affording humus and high-class cultural practice. Many, if not most, successful vendors of special manures are, or have been, cultivators themselves—old gardeners or farmers, or both, who have proved the value of their preparations, kept in touch with their customers' requirements, and also abreast of the times in which they live.—G. ABBEY.

DECORATIVE WORK.

(*Continued from page* 263.)

WHERE a gardener fails to some extent to do justice in the decoration of a large hall or other public building, or a ballroom, any of which under the varying circumstances of life he may be called upon to perform, may be rather from a want of daring than from a paucity of ideas, or even a deficiency of material at hand. One whom I knew who was called upon somewhat suddenly to execute the decorations for a hunt ball to be held in the most country of country towns, sought some advice upon the matter from a friend whose experience of this work was more extensive. Together they discussed the matter upon the scene of the intended festivities, which was a large bare building, offering a fair field for adornment. Good advice was given, and various suggestions made, which were in a way of great service, but in a way only, as our decorator was expected to give a maximum of display at a minimum of expense. He was, in fact, told that with his staff and such material as the shrubberies afforded in the way of evergreens, ample means were at hand, hence flags or other purchased or hired material was out of the question, and flags, his adviser had insisted upon as a necessity. However, our gardening head devised and carried out what merited and obtained unqualified praise.

Flags were a *sine qua non*, so home-made ones filled the breach. Laths, some 6 feet long, surmounted with zinc cut into the form of lanceheads and painted with gold paint, answered that part of the purpose admirably, whilst some yards of red, green, and yellow art muslin a yard wide (of the cheapest quality), and in self colours, composed the flag portion; about 3 yards of the muslin being tacked on to each lath and made to hang in graceful folds by being caught up with a tack at the bottom. A bold trophy of these flags was arranged fan fashion on the end wall of the building, small trophies being disposed between the windows on either side above a dado which is worthy of description. This consisted of 2-inch mesh wire netting 3 feet high run along the wall on either side, into which was closely interlaced sprays of common Laurel, a screen of the same height being stretched across the front of an improvised orchestra which was dressed with small sprays of Portugal Laurel, into which, at intervals, the initial letter of the Hunt Club was boldly interwoven with twigs of variegated Box, sufficiently distinct in its colour to stand out clear on the groundwork. Some well-made wreaths outlined the windows and entwined the gas-brackets, whilst roughly made latticework upon which evergreens were secured completed the furnishing of the end wall, where the trophy of flags was the central feature. The whole arrangement of this hunt ball decoration, simple as it was, afforded the maximum of effect at a minimum of expense, whilst the labour, principally consisting of inserting the Laurel cuttings, was rapidly accomplished by the nimble hands of a few lads directed by the older "Head."

In a roomy hall of this kind a central gas pendant or chandelier offers temptations as a holding from which wreaths may be festooned to the side or end walls. With some little discretion respecting the weight put upon this structure an excellent effect may, under some conditions, be gained; but in one case under notice the strain imposed brought a gas leak, and that confusion at the last moment. On bare walls where windows do not intervene to break the line, or to form a continuous line above them, the employment of a substantial wreath caught up at regular intervals to the wall-plate from which the roof springs will generally exhibit good taste. This wreath hanging in graceful festoons is more decided in character if a substantial rosette made of bright pink tissue paper is fastened on to the wreath at those points whence it depends. Good decorators generally do not favour the use of paper presentments of flowers, or indeed the introduction of coloured paper, wrinkled or crinkled, in any phase of decoration; but it is, in this or similar cases, quite admissible, for distance lends enchantment to the view, and that view is by artificial light. Freshness, brightness, and novelty are the desiderata not difficult to obtain during the duller periods of the year.

Now and again similar work is required during the summer months when the bulk of our evergreens, in the soft and tender growing stage, are totally unfitted for the purpose, yet have I seen them thus used without any discrimination as to their lasting properties. At a military ball contributions in the form of some waggonloads of this unsuitable material were sent in two days prior to the event, and one could only regard the use of it as a waste of labour, even worse, for it is futile to expect any satisfaction from foliage flagging as soon as cut; nor is it easy to find substitutes. However, much can be done in other directions. Trailing Ivy from the woods, growing under trees in preference to that growing upon them, if procurable in quantity, and tied in bundles with the ends placed in water until absolutely required, is very helpful in the way of greenery. In using, five or six long sprays tied together in a handful of damp moss can be fastened at discretion to long narrow laths for wall drapery, or to a mantleboard for ornamentation of a fireplace. Upon these particular occasions heavy effects are neither necessary nor desirable, and the fresh green

of Ferns in pots with plenty of moss, some bright flowering plants, and a few stately Palms may be all-sufficient for the purpose. In most cases of this kind the decorator will, probably, have to work with a restricted hand so far as any obstruction of the floor space is concerned.

The decoration of a private mansion for a social function offers great opportunities for the gardener to display good taste and artistic ability, and when called on to execute it he should, with this power in his hands, think himself happy if, in rising to the occasion, he is able to express his ideas. With examples furnished by our eminent tradesmen, who as decorators carry out to order those magnificent schemes, exalted into a fine art, and exhausted in a wealth of choice flowers and foliage, we have naught to do, although it is good for gardeners, if opportunity occurs, to criticise all details, to note the strong points, and weak ones if there are any to be found. With what a gardener may be called upon to do, with what he has to do it with, and how it may be done, is our immediate concern. By taking as an example the successful treatment of the festive decoration of a mansion, we may next study the question from the hall door, where it commences, to the reception rooms and the staircase, where the principal features and the greatest possibilities occur. It may be here remarked that the expert decorator is always anxious to avoid working upon stereotyped lines, and although always ready to notice any particularly good or striking effects, they are more of service to him as suggestions than as models to be closely copied.—DECORA.

(To be continued.)

IS GARDENING DECAYING?

SOME EXCUSES AND A MORAL.

THE gardening fraternity of the present day flinches from the challenge which I threw down a few weeks ago. Silent are the men who are heard at the shows loudly glorifying their productions, silent are they whose voices and pens are most frequently at work in mutual laudation. Not a word has been said in disproof of the indictment which I levelled at the present aspect of horticulture, and the charges I made stand firm on the rock bed of unassailed accuracy.

What a picture it is! For years past I have been watching the development of gardening into a vast mutual admiration association, in which, instead of labouring to raise their standard of knowledge, the members extol their own and their neighbours' commonplaces, for all the world as though they were better, rather than worse, than those of past years. Yet when someone comes forward who has lived long enough to perceive the fallacy of it all, and has the temerity to speak what he thinks, these pusillanimous heroes lurk in the rear, unable to say a word of exculpation or justification.

The fact of the matter is that a nice warm, comfortable camp had been formed, a place where the members of the mutual admiration association fancied themselves snug and secure. Into this camp a shell suddenly dropped, scattering the talkers and writers in all directions. Such, I suppose, was their confusion and discomfiture, that they were unable to gather their forces for one poor little volley; and so I return to the charge again, prepared to maintain my position, and, indeed, only too anxious to drag from their obscurity the champions—if there are any—of the new order of things.

In what has transpired as a result of my article, nothing but what is corroborative has appeared. Is not this significant? An apologetic tone has been in most cases assumed, but the broad result is an admission of the truth of my contentions. Let me now glance at some of these apologies. One writer, beginning with a compliment to my literary abilities which I neither deserve nor covet, passes on to refer among other things to the increase of decorative work as a reason for the decay of sound general practice. Of all the excuses which could be brought forward, this is surely one of the lamest. Was there, then, no decorative work done in the old days—work that would vie with the vaunted efforts of the present time? Why I, whom this correspondent insidiously attempts to disarm with laboured compliments, have probably spent more time than he has in some of the most delicate and at the same time extensive "furnishing" ever carried out in this country. In truth, such trivial excuses as excess of indoor work are futile.

It would be amusing, if it were not melancholy, to perceive the attempts that are being made all along the line to raise side issues. I have, I see, set a few of the professors by the ears with regard to the question of wall fruit. Here, again, no endeavour is made to repel my arguments, but a cloud of dust is blown up, as if that would help us to see daylight. If my position were seriously assailed, which it is not, I should have abundant comfort in the fact that as the clever men who are at issue with each other are using up all the dainty epithets they can find I should certainly be spared. I do not doubt that they are "stupid," I am not going to question the fact that they are talking "nonsense;" I only want to make it clear that that is not my style of argument, but theirs.

But what, after all, does all this talk about the decadence of wall fruit amount to? Let us have done with the mutual admiration association, and face the facts. It is admitted that there is great deterioration, although no one appears to have had the courage to state the case in plain words, and the question I want to ask is this, If a gardener had an important department under his charge, which he perfectly understood the demands of, would he not find some means of giving it at least as much attention as was necessary to keep it in a tolerably satisfactory condition? Would he let his Chrysanthemums, for example, destroy his fruit? Assuredly not. It is because our gardeners are getting into the way of thinking that half a training is as good as a whole one—that as soon as they have completed their first year in the bothy they are qualified to take a head place—that things are drifting as they are. Why disguise the fact? Why not face it like men?

There is much in the statement that Chrysanthemums have a good deal to do with the decay of all round gardening; but it is not because the plants simply take up a great deal of time, it is because a race of men is springing up who know very little about anything else but these overrated plants. The thing is as plain as the day. Ladies pay a considerable amount of attention to Chrysanthemums for a week or two in the autumn, and consequently a collection is grown much too large for the place. This thing is bound to be attended by a reaction. Masters are beginning to find out that it is not worth while to spend large sums just for the privilege of hob-nobbing with a handful of squabbling specialists at an autumn show. The Chrysanthemum is already on the decline, and when the time comes, as come it will, for the word to be passed round among the gentry that the costly Chrysanthemum "collection" is to be reduced, woe to the man who has for so long existed under the notion that his knowledge of the culture of one plant will enable him to pass muster as a good gardener. A Nemesis is pursuing him, and the signs of its approach are already apparent.

I am not sorry in one sense that this point of the Chrysanthemum has cropped up in the discussion which followed my first letter. Traverse, if you will, the length and breadth of the country, as I do, and you will find, as I have found, that the egotism which prevails amongst our modern gardeners only assumes its worst phases when a Chrysanthemum circle is formed. I have attended many Chrysanthemum shows, and listened to many Chrysanthemum papers, and the conclusion I have come to is this—that the impression is common that the universe was designed specially for Chrysanthemum growers, and will revolve round them until the end of time.—TRAVELLER.

[Our trenchant "Traveller," who has suddenly appeared to sparkle like a new star over a degenerate world, does not say anything about Shrewsbury. We would now suggest his attending the November show of the National Chrysanthemum Society—if he can find room. We let the "squabbling specialists" stand as the greatest novelty of the season up to date.]

ARE ROMAN HYACINTHS POISONOUS?

ONE is inclined to answer this question in the affirmative, judging by the intense irritation set up by handling the bulbs. This effect is, however, not common to all, as some people can handle the bulbs with impunity; and it is, I believe, not at all certain whether the annoyance experienced by some is due to a poisonous principle in the cuticle of the bulb, or to some kind of abrasion consequent upon the presence in the skin of the bulb of myriads of minute needle-like crystals of calcium oxalate (raphides).

These acicular crystals are common to all Hyacinths, but I have never known any bad results from handling the ordinary Hyacinths, so that evidently there is some peculiarity of the Roman Hyacinth that needs further explanation, especially so as it is merely a variety of the common garden form (Hyacinthus orientalis). The crystals appear to be as plentiful in one variety of the Hyacinth as the other, so that so far as quantities of these little raphides go I do not think there is anything to choose between the two.

Anyone in possession of a microscope can with ease examine these crystals, with an inch or a quarter-inch objective. The preparation is very simple. Tear off a shred of the cuticle and soak it for a few hours in methylated spirit, then clean it by soaking it again for a short time in clove oil, when it can be mounted in Canada balsam. Some faint idea of the myriads of crystals can then be formed by comparing the size of the shred of skin examined with the numbers of raphides on the field of the glass. The form of the crystals can be better seen by using the polariscope.

Your correspondent "J. C." asks for a remedy or a preventive. The latter is very easy—wear when handling the bulbs a pair of old kid gloves. It is better even to run the risk of being thought "a kid-gloved gardener" than to suffer the irritation.—JOHN W. ODELL, *Stanmore*.

ORCHIDS

Saccolabium bellinum.

S. BELLINUM (fig. 46) is small compared with most other Saccolabiums, though of similar habit, the leaves being arranged in a two-ranked manner, and the flowers are very distinct in form. Their chief peculiarity is in the lip, which at the base is expanded in a strange cup-like manner; the apex is flattened and, extending at right angles with the cup, resembles a platform upon which bees or other insects may alight. The surface of this platform is covered with short white filaments, which impart a strange appearance to it when closely examined. In colour the flower is not very remarkable, though there are some curious contrasts. The sepals and petals are yellow, or with a greenish tinge, on which are scattered several circular dark red spots; the base of the lip is white with crimson dots, and the centre yellow with purple dots. The spikes are small, bearing from three to four flowers each, and though unpretentious in general appearance it will become a favourite with lovers of many interesting diminutive species of Orchids.

Cool Orchids.

There is no section of the Orchid family more interesting and beautiful than the numerous species and varieties inhabiting the higher mountainous parts of the tropics, and therefore thriving under cultivation with very little artificial heat. In the family of Odontoglossums there are many chaste and lovely forms that can hardly be equalled, and certainly not excelled, by any requiring great heat. The graceful spikes of some in the cool section of Oncidium are unsurpassed in lightness and elegance, while in bright and glowing tints the cool house is exceptionally rich.

Disa grandiflora, Epidendrum vitellinum, Sophronitis grandiflora, Ada aurantiaca, and all the showy Peruvian and New Grenadan Masdevallias. These form a rich array of colour, and every one may be grown in a house kept just comfortably warm in winter, and in summer as cool and moist as heavy shading and abundance of air and moisture can make it. Lycaste Skinneri, in its many beautiful forms, is a host in itself, while quaint and structurally interesting plants are found in plenty among the Restrepias, Pleurothallises, and the tiny growing kinds included in Oncidiums and Masdevallias.

Each of these classes of Orchid flowers finds its own section of admirers, and for those desiring a representative collection it is fortunate that they may, as far as atmospheric conditions are concerned, be somewhat collectively treated. All of them abhor a dry, parched, or draughty atmosphere; what they like is the air about them from May to September kept saturated with moisture, a more or less dense shade, and frequent supplies of water to the roots. The quantity required varies, of course, with the different kinds, and their seasons of rest and growth have to be carefully noted and followed as far as possible.

To take two well-known kinds as a contrast, I may mention Oncidium macranthum and O. concolor. No one acquainted with the habit of these two species would think of potting them similarly. The pretty little self-coloured kind would not need anything like so large a pot or so rough a compost as its stronger-growing and vigorous-rooted compeer. Then the O. Marshallianum and nearly allied kinds come almost intermediate between these types. They cannot take hold of a large body of rough compost like the strong-rooted macranthum, on the one hand, but on the other the rhizomes are more given to extension than those of the tufted growers like O. concolor. This sorting of the different kinds and allowing each its proper stamp of receptacle and quantity of compost, has an important bearing on the well-being of the plants.

Masdevallias, as a genus, do not like a large body of material about the roots; they must have enough to keep them moist all the year round, and room for the little twining roots to get a hold, but anything beyond this is superfluous, not to say harmful. Quite a different stamp of root is that produced by Disas. These like more room, and a very rough material, that air can enter and leave freely, and which also takes up plenty of moisture, and does not part with it too readily. Lycastes do not produce large roots, but they are very persistent, and will push through a quantity and quality of compost that would kill many of the more sensitive kinds.

Then, again, as to the time of repotting; this varies almost as much as the other points referred to. Many of the Odontoglossums do not produce a root until the growths are quite half formed; then as the plant requires more nourishment to swell up the pseudo-bulbs, these are emitted to forage for it. To anticipate this flush of young roots, which occurs more or less with every Orchid, and to repot just in time for them to have the advantage of the new material, is sound practice, and bound to be productive of good results.

It will be noticed that with the plants referred to the roots usually appear in autumn, and the present is therefore a good time for a look round the majority of dwarf-growing cool house kinds. The peat and moss used for them should be of the best quality obtainable, all sand and earth being removed from the former, and any foreign substance, such as grass and small sticks, picked out carefully from the latter. The mode of potting is not exactly the same with all species, but cleanliness of material and pot, good drainage, and a neat tidy finish are points always needing attention.

The summer treatment of the cool house, as mentioned above, consists in keeping it as cool and airy as possible, without causing a dry or draughty atmosphere. The inside of this structure in the hottest weather should always feel agreeably cooler than the external air, or something is wrong. This is a far better test than running to the thermometer, and keeping this at just some stated figure. The winter treatment must be to carefully regulate the temperature according to outside climatic conditions, to have the glass as clean as possible by frequent mopping down outside and sponging inside, and to keep the heads of all the plants as near the glass as possible. I hope to refer to some of the principal cool house kinds in greater detail shortly.—H. R. R.

FIG. 46.—SACCOLABIUM BELLINUM.

TRAINING FRUIT TREES.

I HOPE many of your correspondents will follow the suggestion of "H. D." (page 260), and let us have this matter thoroughly ventilated, not only with regard to the present deplorable condition of so many trees, but also to see if we cannot do something to improve this important brauch of gardening. I do not record my vote with your correspondents who attribute the decadence of fruit management to increased floral and plant decorations, as the men to whom this work is entrusted seldom have anything to do with outside work, any more than the labourers are called upon to take an active part in the growing of plants under glass. I make bold to say that men, and not means, have more to answer for in the matter of failures in fruit growing than have plant and floral decorations.

In reference to the commercial picture drawn by "An Old Provincial," I take it as a matter of regret that there are not more noblemen and others who prefer to get as much out of the land as possible in preference to letting it go practically out of cultivation. Why a nobleman should make any secret of starting an emporium I cannot see. I look upon him as a public benefactor, for he not only benefits himself, but the consumer and the labourer. What is more fitting than that

landowners with capital should put it into their own land? Deep and thorough cultivation is a good investment, from which themselves and others derive benefit.

We hear of enormous sums of money going from this country for produce, some of which at least can be produced equally well at home, and those who try to encourage home industries are worthy of the gratitude of all classes. Gardens, I take it, are to a large extent luxuries, and if an owner finds it necessary to reduce the expense of his garden, before dismissing the men, would try selling at least the surplus produce, his garden would still give him satisfaction and the labourer not be deprived of his employment. This selling business opens up such possibilities that I have wandered somewhat from the subject; but now for a practical suggestion.

Let Peach trees be pruned directly the fruit is gathered. Cut out all weak and unhealthy wood. Make no mistake on this point. Cut to wood that is able to mature a crop. We should have finer fruit and heavier crops if half the wood that is generally left in trees for bearing was removed at the right time. Apricots, Plums, and Pears should have the spurs well shortened back, old and unhealthy spurs cut out, and strong young wood laid in where there is room for it. This work ought to be done before the leaves fall.

I now pass to the roots, and here I think lies the cause of many failures. It is no use expecting profitable crops of fruit if the roots are deep in subsoil. They must be under control and where they can have nourishment. Those who have still model trees of our forefathers would do well to try lifting. Take one side of the tree; throw out a trench 3 feet deep, and work all the soil from about the roots, and prune damaged ends. If the soil at the bottom is very bad it can be wheeled to the refuse heap; it will be useful to bank up the fire. Return the best soil, mixing charred refuse and mortar rubbish with it, making the whole firm. Lay the roots near the surface and mulch; this with another mulching in May, a good wash once or twice with a good engine during the growing season, and a watering any time of the year that men can be spared, will improve the quality and quantity of our wall fruits.

Most gardeners are short-handed, I know, but do we not sometimes give too much time to the November Queen? Does it not take a long time to pull out those stiff and damaged petals, and to place those small stakes to prevent the "Mums" breaking their necks? How would it be to say to some in this department, "That will do, get on, I want you outside for a change?" Those who have real interest in gardening would welcome the change. Then, with spade and fork, and an example from their chief, a great deal would be done to check the decadence of fruit culture.

In summer pruning, do not let a man start nailing unless you are satisfied that he will not tie in ten shoots where one only is required.

One more reference to decorations. What is more appreciated than good fruit? It is as much admired as any floral display, and takes as prominent a place on the table as any decorations.—S. B. O.

What is the Jumble System?

I HAVE just fitted a new pen to my holder to compliment "Melton" upon the improved style of his latest contribution, "Training Fruit Trees." What a beautiful picture is presented to our mind's eye by the affectionate terms in which he writes of "E. D. S." He seems so grateful to him for coming to the rescue, that one is almost tempted to think the latter is a second edition of the former. I fully agree with both as to the necessity of training the shoots of fruit trees thinly. Keep them thinly disposed, is a maxim I have always preached, practised, and intend to continue.

It is bad form I know to quote too freely from an opponent's writings, but convenient to do so occasionally. Note this from the pen of "Melton." "I have not seen a man yet who has been able to train and attend to three or four branches, and to complete the work, in the same time as he would finish one." Well, let me add, that depends upon their length; if the three or four were very short, and the one very long, the feat might be easily accomplished. It is not the mere nailing up of the branches that takes the time in training trees, but the perpetual pulling, twisting, and straining necessary to get them perfectly straight. In order to do this extra nails and shreds are often required, yet the less used the better for the health of the trees. Let us take, for example, two Peach trees of equal size; all good growers would leave the shoots from 6 to 9 inches apart, according to the size of the wood. Now let us suppose that two gardeners, equally expert at their own particular style of training, begin to nail the trees at the same time, the object of each being to dispose the bearing wood as evenly as possible over the surface of the wall; but one must train every branch perfectly straight, "in the style of the old masters," while the other does not mind a few bends, slight curves in a shoot, so long as the general outline of each is fairly correct. Which of the two would finish their tree first? Is there a single reader of "our Journal" bold enough to say the disciple of the "old maters" would? If there is, I should like to nail a tree against time with him.

While taking a pleasant walk in connection with my daily work I recently saw a fisherman skimming the surface water of a lovely river. I watched, and found that he "skimmed" for a purpose, that he was throwing a bait. After a while I heard a splash, the line run out, and soon the beaming fisherman landed a monster pike. I went a little farther. Another follower of "Walton" sat upon the river bank; beside him were two rods and lines with well-baited hooks attached. "Much sport to-day, my friend?" I inquired, as usual. "Only them two little 'uns, after two hours' fishing," was the reply. This man fished deep in the waters, and got little for his pains, while the "skimmer of the surface" obtained a fine reward.

"Melton" has tried to show how many and far reaching are the causes which have led to a change, if not decadence, in the training of wall trees, yet he has practically arrived at the same conclusion as I—who according to the sage from the hunting centre—have been "merely skimming the surface." The gist of his argument as well as mine on this point is, that the change has been brought about by the pressure of work in other directions, though the pressure may be felt in different ways in each particular place. Still we have much to be thankful for. Fruit is grown as well—nay, better than ever it was—how then can the "glory of our garden walls be departed?"

Yes, I am thankful to know that at least one old gardener is induced to think that I know just enough to be able to train a tree properly, notwithstanding my preference for fine fruit instead of straight barren branches. If I have not planted and trained the same set of trees for a period of twenty years, I have done the work from start to finish, until the trees have covered their allotted space. I have also done something which I consider far more creditable - viz., taken charge of old trees which have not borne a crop for years, and brought them into a fruitful condition, by cutting out some of the old branches, and training in the—to some—horrible side shoots. The many years I had charge of the trees which caught the eye and took the fancy of the "guiding spirit" were quite numerous enough to spoil them, and if I did not train them from their infancy I did train many others in the same garden, which to-day stand as monuments to the soundness of their early training.

Now let us note the eleventh paragraph on page 283. "Melton" is a little too previous in assuming he has placed me on the "horns of a dilemma." The trees I wrote of as having caught the eye of the "guiding spirit" were Morello Cherries, and every gardener knows that they produce wood so freely over the entire surface of the tree, that no matter whether they are trained well, badly, or not trained at all, they will bear good crops if the cultivator will thin the shoots a little. All trees, however well managed and trained, are liable to lose some of their branches; then, as I have pointed out before, a gardener has to choose between long inside branches or having blank spaces on his walls, as the rightly placed shoot is not often obtained. "The best trained and managed trees and Vines remain productive the longest, do they?" Who has not heard of the Penrhyn Vines with their "faggots of wood?" and who, I ask, does not covet the grand Grapes they produce?

Yes, I have seen cordon Pears roped with fruit, and I have seen a good many others which have not for years borne a good crop, though in each case they were under the management of good fruit growers. If I had unfruitful ones of this description to deal with I would lift and replant them, and if that failed train-in the much-despised side branches. A few days ago I accepted a long-standing invitation to visit the noted and extensive garden of an earl. The genial gardener is one who has made a name in the horticultural world, and intends to maintain his reputation as a fruit grower. Of course, I noted carefully the condition of the fruit trees, especially as the chief had a sound training in tree manipulation in the best Scottish gardens. He prides himself on well trained trees, as long as they are fruitful; but he has seen the advantage of breaking away from the old mathematical style. Here is a case to the point: One high wall was planted with Pears considerably more than twenty years ago—the training adopted was the horizontal style. All went well till the trees had no room for extension, then they gradually decreased in fruitfulness. The next move was to remove every alternate branch and train-in side shoots at regular intervals. The result of this departure was so satisfactory that others have since been treated in the same way.

Many other similar instances may be met with in various parts of the country; in fact, whether "Melton" knows it or not, gardeners as a body will never again keep closely to the mathematical style of training adopted by their forefathers. The system has been tried in the balance and found wanting, and since the generation or two ago, when changes in this direction were beginning to be made, good crops of fine fruit have gradually become more plentiful, but the full advantage of this change in training will be seen in the years to come. I wonder what "A Traveller" and "Invicta" are doing? Have they employed "Melton" to extricate them from an untenable position?—H. D.

THE ONION CROP.

THIS will, in the majority of instances, have been stored by this time, and judging from my own experience, and from that of others in the neighbourhood, the yield has been a thoroughly satisfactory one. The bulbs, though not exceptionally large, are clean, firm, and well ripened. A few weeks ago, when wet weather prevailed, many cultivators were sorely puzzled about what to do with their Onions, as experience had taught them that if wet weather continue for a long period, many of the bulbs will split and begin to grow again at a time when they should be ripening and becoming firm, conditions absolutely necessary for good keeping. Just in the nick of time, however, the weather changed, and instead of sunless days we were blessed with bright drying ones.

Fortunately I took the first opportunity of having our crop pulled up, and the bulbs turned with their roots facing the sun. With a little further attention in the way of turning the bulbs occasionally, thanks to the settled weather, the ripening process was soon completed, and the "Onion loft" is now groaning with the weight of a bountiful crop. At one time I took a great pride in growing a few rows of large specimens, simply for the sake of having the satisfaction of pointing to a few great ones, but I found they were not appreciated in the kitchen. A large supply is wanted, but the cry is always for small Onions, which are as useful for flavouring and making up into a variety of dainty dishes. This year I therefore left about half the crop unthinned, so there is no lack of "picklers," and others of still smaller size to suit the wants of the most fastidious chef.

In these times of depression in agriculture, and to some extent in market gardening, many might do worse than seriously turn their attention to the culture of Onions on a large scale, especially to the production of "picklers." A wonderful yield could be obtained from a single acre with little outlay in cultural operations. A medium or rather light soil would answer the purpose well. There is plenty of such land to be had cheaply enough. For many crops it would require to be heavily manured; for this one a heavy dressing of soot would suffice, as a rather poor soil is a great aid to the production of small firm bulbs. Deep digging should be practised, however, to enable the young plants to withstand drought. Land cleared of late Broccoli would answer admirably, as the seed need not be sown till the first week in May; the Onion crop could then be cleared soon enough to plant Cabbage in September. This would introduce a crop rotation to keep the land constantly going, and in great contrast to much of it at the present day.

I have tried the plan of sowing the seed broadcast, but do not like it on account of the difficulty of keeping down weeds. If it is sown in drills 8 inches apart, there is plenty of room for the development of both tops and bulbs, as well as for hoeing between the rows. Some will perhaps think Onions grown in the way indicated a risky undertaking, owing to the serious consequence a bad attack of maggot might have. This season we have certainly been very free from it, and under no circumstances do I think it would seriously injure the crops if the plentiful use of soot is persistently indulged in. This, as I have previously stated, should be freely worked into the land before sowing takes place. As soon as the seedlings are clearly visible, another dressing ought to be given in showery weather, to be followed by others till the dangerous stage is passed.

I have never known this plan fail, though I have seen it tried in many districts where maggots were causing disaster around, and I have heard some maintain that soot is not effectual with them; but I think, in such instances, it is generally a case of "letting the horse out of the stable before the door is locked." With a population increasing by leaps and bounds, it behoves Britishers to look to the requirements of the future, instead of calculating only upon the present demand, and those who are fortunate enough to see the farthest are likely to reap the greatest reward.—KITCHEN GARDENER.

EXCELLENCE IN PEAR CULTURE.

THE success of Mr. Kean (F. Williams, Esq.'s, intelligent gardener at Watchbury, Barford) in the Pear classes at the Birmingham Chrysanthemum Show last year caused me to make a mental note to endeavour to see his fruit on the trees another season. Having received a hearty invitation to do so, I thought I might venture to take the trip on that labour-saving wonder, the modern "bike." I felt it was a rather risky undertaking for one so old and grey as "H. D.," but then I remembered that the roads were good, and so screwed up my courage to make a bold venture on a very substantial "Safety," fitted with a powerful brake. I reached the pretty village of Barford after the expenditure of perhaps a good deal of unnecessary force. I am not sure that the pace was great, or that I steered a very straight course, still I got there, and found my friend, Mr. R. Jones, ready to bear me company in search of productive trees and gigantic Pears.

Under the guidance of Mr. Kean we soon found plenty of both, and in a short time I was thoroughly convinced that I might go a long way before meeting with an equally good collection of really fruitful Pear trees, in which good culture and well selected varieties show clearly what grand Pears can be grown in the heart of England. In a large garden the high brick walls were entirely covered with Pear trees, and I do not remember seeing a single blank space.

Around the sides of the walks pyramids are planted at good distances apart. One vigorous pyramid was carrying a very heavy crop of that fine stewing Pear Bellissime d'Hiver, a crop which, if judged by its market value, must be an extremely remunerative one. Léon Le Clerc de Laval, on the wall, also had a heavy crop. Catillac, though rather a thin crop, was represented by fruits of great size. General Todleben was also conspicuous by reason of the size of the long fruits—large enough, in all conscience, to serve as a feast for a giant. Beurré Bachelier, Beurré Clairgeau, Gansel's Bergamot, Durondeau, Glou Morçeau, Thompson's, Passe Colmar, were in good condition, the fruits being clean, and the crops varying from fair to heavy.

Upon specimens of Souvenir du Congrès and Pitmaston Duchess the highest praise must, however, be bestowed. These were grand in every way, the size being wonderful, and the absence of speck or blemish particularly noticeable. Mr. Kean has good reason to be proud of his fruit as well as the fine condition of the trees.

Now for a word about the training. It is done well, but not quite in the style of the old masters, for wherever a vacant space occurs a shoot is trained in to fill it. If a well placed one can be had so much the better, if not, the nearest one is selected, without waiting for it to appear in the precise place in which a Meltonian must have it.—H. D.

COTONEASTERS.

LIKE many other ornamental fruiting shrubs, the Cotoneasters are now at their best, and it may not be out of place to draw attention to a few of the most noteworthy for general garden work. Roughly speaking, they may be divided into two groups—"evergreen" and "deciduous." The former we will deal with first.

Among tall-growing ones we find C. buxifolia, C. Simonsi, and C. rotundifolia, all good growing and free-fruiting species. C. buxifolia, as the name implies, has foliage resembling, to a certain degree, that of the common Box. The leaves are about the same size as those of the Box—olive green above, whitish (from the presence of a quantity of silky hairs) underneath. The fruits are bright red, and produced one or two together from short secondary branches or spurs on the old wood. It is a dense grower, and if allowed perfect freedom will in a few years make a perfect thicket. It is a native of the temperate Himalayas.

In habit, C. rotundifolia resembles the preceding to a great extent; the leaves, however, are rounder and slightly larger. The fruit is very similar to that of the former. C. Simonsi is one of the most common species, and well known in most gardens. It is of more upright habit, and is not so dense as the two before mentioned. Like them, though, it is a Himalayan plant. The fruit is orange and red, and produced in abundance.

Of dwarf growing evergreen species we have C. thymifolia, C. horizontalis, C. microphylla, and C. microphylla gracilis among the most distinct and useful. All are from the temperate Himalayas. C. microphylla is often seen trained to walls or growing on rockeries. It adapts itself well to this kind of treatment, for, when planted in good ground, it grows quickly and soon covers a good sized space. Grown either way, the small, pretty foliage and red fruit make a very pleasing sight during autumn and winter. C. thymifolia does not appear to fruit so freely as some of the others, but it is worth growing for its usefulness as an evergreen. Its small Thyme-like leaves are very distinct, and the plant makes a good one for rockery or border.

C. horizontalis appears to be a connecting link between the evergreen and deciduous, for although the leaves fall before the new ones appear they are usually retained until early spring. It is one of the prettiest of the dwarf section, whether in or out of fruit. The leaves are about a quarter of an inch across, deep green and glossy; before falling they usually turn to a pretty orange red. The bright red fruit is produced erect on the branches, and peeping out from among the bright green foliage looks charming. It is seldom seen more than 1 to 1½ foot in height, but branches and widens quickly. It is a very suitable plant for covering a bank or growing on rockwork.

Of the deciduous species the following may be taken as the best—C. frigida, C. vulgaris, C. laxiflora, C. pannosa, C. bacillaris, and C. bacillaris floribunda. Taken from a fruiting point of view only, the Himalayan C. frigida is by far the most beautiful that has been mentioned. It makes a large spreading bush 10 or 12 feet or more in height, and produces with great freedom large drooping heads of scarlet fruit. C. vulgaris, or as it is now called C. integerrima, is the only one found in the British Isles, being occasionally met with in the neighbourhood of Llandudno. The fruit of this is black. C. bacillaris is a tall, coarse growing Himalayan plant. It is well adapted for growing in plantations where it can have plenty of room. It fruits freely, the fruit being dark purple, almost black. C. bacillaris floribunda is an improvement on the type. It is not so coarse growing, produces more fruit, and shows it off to better advantage. C. laxiflora and C. pannosa are grown more for the sake of their flowers than fruit. Both have a light and graceful habit, and produce their white star-shaped flowers in great profusion. The home of the former is Siberia, and of the latter Yunnan.

Given a light, sandy loam and sunny position, a selection of the best of these shrubs will be found to be a useful and interesting acquisition to any garden.—KEWITE.

Notes & Gleanings

EDITORIAL NOTICE.—It is particularly desired that all communications, parcels, catalogues, and newspapers intended for the EDITOR, be sent direct to 8, ROSE HILL ROAD, WANDSWORTH, S.W.

—— WEATHER IN LONDON.—Comparatively little rain has fallen during the past week in the Metropolis. On Saturday night there were a few local showers, but Sunday was fine throughout the day, as was Monday. On Tuesday there was a steady rain for about a couple of hours in the morning. but the rest of the day was dry, though dull, a slight mist coming up towards night. At the time of going to press on Wednesday it was fine.

—— THE WILL OF THE LATE MR. CHAS. SHARPE.—By his will of the 4th April, 1895, with a codicil of the 4th February, 1897, Mr. Charles Sharpe, of The Pines, Sleaford, J.P., and of Charles Sharpe and Co. (Ltd.), seed growers, who died on the 8th March last, aged fifty-seven years, leaving personal estate valued at £73,664 4s. 11d., appointed as executors his wife, Mrs. Elizabeth Sharpe, and his son-in-law Augustus Leverton Jessopp, of Leasingham. He desired, but without imposing any obligation on the trustees, that his Heckington property should remain, as he had applied it, for the purpose of allotments and small holdings.

—— A BUSH WISTARIA.—One of the oddest things I saw when visiting Bicton Gardens recently was a bush Wistaria. The growth in its early and ductile days had been wound round and round a stout stake or other support, until now the stem resembles the coils of a serpent, as sometimes presented in pictures or in statuary. The coils were quite close together, and showed how facile for such forms of training the growths of the Wistaria are. The head is a dense mass of spurs, being every year hard pruned or cut back, and in its season it is also a mass of bloom. It is strange that this beautiful flowering plant has not been more largely grown in this way, for it is easily kept compact, and as it spurs so freely soon makes a massive head, which in due season blooms profusely.—D.

—— THE FRUIT FLAVOUR PRIZES.—"A Country Gardener" informs me that in relation to these prizes no less than sixteen!!! exhibitors competed during six months last year. Really, I must say, as was once said of the five Barley loaves and two small fishes, "But what are they amongst so many?" I apologise for being wrong with reference to Kerry Pippin, but "A Country Gardener" admits that it had not previously to the meeting on October 17th received an award. That was just what I meant to convey. Last year Ribston Pippin came out badly. This season it has already taken first place with very handsome and finely flavoured fruits from Syon House. I hope to see other good standard varieties coming to the front later on.—D.

—— KALES AT CHISWICK.—In a few weeks the Fruit Committee will, I learn, have to examine a large collection of Kales, now growing in the R.H.S.'s Gardens at Chiswick, and growing, too, very luxuriantly. It will constitute a very interesting meeting, because apparently every known, and perhaps unknown, variety of Kale seems to be found in the collection. The trial should have exceeding interest for Scotsmen, as the northern men are credited with a high appreciation for Kale, although they usually spell it Kail. An odd feature is seen in the exceeding luxuriance in growth of the many, and of almost extermination of the few. Those are of the deliciously tender (when cooked) Breda section; they have been almost eaten up to extinction by some interesting but destructive fungus, yet have left the broad-leaved thousand-headed forms unharmed. No doubt there has been from time to time a good deal of intercrossing of Kales, Cabbages, and Savoys, hence the odd forms found in the collection. If the Committee had samples cooked to taste their duty would be indeed an onerous one; but, probably, whilst testing boiled Potatoes, will leave the Kales severely alone. These, it is of traditional averrance, are never fit to eat until well baptised with sharp white frost. In any case we do know for certain that they never eat so tender or so sweet as when partaken of during severe weather. Kales or their wonderful variety, apart from all other members of the Brassica family, serve to show the variations of which B. oleracea is capable. When, however, every other variety of every other section is added, then indeed is the product almost marvellous.—A.

—— SWEET PEAS.—The correspondent who asks for a report of these may like to know that we have found Eckford's by far the best. The only American one that is superior is that named "Blanche Burpee."—F. W. B.

—— UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—The annual dinner of the above Institution will be held at the Holborn Restaurant, on Tuesday, October 12th, at 6 for 6.30 P.M. Mr. H. B. May will preside at this, the eleventh meeting, and it is to be hoped the gathering will be a great success. Tickets may be obtained from Mr. W. Collins, 9, Martindale Road, Balham, S.W.

—— LASIANDRA MACRANTHUM.—Perhaps better known under its old name of Pleroma macranthum, this is a welcome addition to the few greenhouse plants in bloom at this season. The flowers, which are of a beautiful deep violet-purple colour, are freely produced at the ends of the shoots in branchlets, and although the flowers only last about twenty-four hours, new ones open every day, and the flowering season continues through several weeks. From cuttings inserted in April we have now nice bushy plants in 6-inch pots, but to grow this plant most successfully, says a writer in an American contemporary, it requires to be kept two or three years and trained on a wall or tied to some wires on the side of a cool house. With a fair amount of root space under such conditions it blooms for a long time and commands attention from all who see it. Lasiandras are of the easiest possible cultivation. They are not seen in many places, probably owing to the short-lived nature of their flowers and the fact that they have no value for cutting.

—— WHO SPLICED THE GRAPES AT THE CRYSTAL PALACE?—I had not the least intention to take part in the controversy that has arisen over this very unpleasant matter, until invited by the exhibitor in question to kindly look into his garden and see what Grapes he had, and how far it could have been needed on his part to attempt to patch bunches with intent to deceive. I saw these, and many bunches had been cut in the interval—plenty of fine bunches that needed no packing, and I thought, with all due deference to some of his critics, afforded ample evidence that no effort on his part to deceive was required. At the time the bunches were boarded ready for showing, the exhibitor himself was engaged in preparing the dessert in the house for a dinner party, and his foreman was at Shrewsbury. Therefore he had to trust to one of his young men, with the help of a labourer, the duty of preparing the Grapes, and it seems in so doing shoulders were broken off through improper handling, and being afraid of a severe reprimand, the shoulders were surreptitiously tied on, then boxed, ere the exhibitor was at liberty. Next morning, having over sixty entries to stage, the fruit was left to the foreman, who had during the night got back from Shrewsbury, naturally very tired, and who knowing nothing saw nothing, and the exhibitor was himself absolutely ignorant of anything wrong until his attention was drawn to the matter on the second day. The assistant did not realise the harm he was doing, because if he had at once told of the disaster, other bunches could have been cut to replace the damaged ones.—A. D.

—— DEATH OF MR. HENRY READER WILLIAMS, J.P.—It is with much regret that we have to record the death of the above named gentleman, which occurred at his residence, The Priory, Hornsey, on Monday morning last. The deceased gentleman was the head of the great firm of wine merchants, Messrs. H. R. Williams & Co. of Lime Street, City. He was a most benevolent man, and for many years closely associated with the late Lord Shaftesbury in works of temperance and charity. Mr. Williams made the chief object of his lifetime the furthering of the work of the King Edward Ragged School, and has been instrumental in supporting, clothing, and educating hundreds of homeless and destitute children, who were trained to occupy useful positions in life. He was the first Chairman of the Hornsey School Board, and was for many years Chairman of the Local Board. In commemoration of his work on the School Board two scholarships available for Hornsey children were founded, and when he resigned the Chairmanship of the Local Board a handsome clock tower was erected by the inhabitants of Hornsey in the Broadway, Crouch End, as a testimony to his public work. Mr. Williams was twice Master of the Worshipful Company of Fruiterers, and in 1889 offered a prize of 25 guineas, to which his friend, the late Dr. Hogg, added a gold medal, for the best essay on "Profitable Fruit-growing for Cottagers and Others with Small Holdings." A copy of this work was graciously accepted by Her Majesty, with a present of fruit from the memorable Guildhall Show in 1890, of which Mr. Williams was an active supporter. He was esteemed by all who knew him, and his death will be widely and deeply mourned. The deceased gentleman was seventy-five years of age.

—— TROPÆOLUM SPECIOSUM.—Your correspondent's note on the above, in last week's Journal, reminds me of a beautiful sight I saw in the flower gardens at Chillingham Castle in the month of August. Two Yew hedges, running parallel with the whole length of the garden, were a perfect mass of scarlet. A few plants had found their way, by accident or otherwise, to the roots of the hedges, and Mr. Henderson last year increased these, and covered the whole length, with the above beautiful result. The fine old wall bounding the garden on the western side had also some masses on wire supports of the same beautiful climber, which, viewed from the terraces above, have a fine effect.—T. H. BOLTON.

—— DAVALLIA FIJIENSIS.—A few weeks ago, on a Saturday afternoon, whilst working in a fernery of which I have the charge, I had occasion to get up to a large hanging basket, containing a plant of Davallia fijiensis, which at this time of the year is usually thickly covered with a yellowish-looking powder. I was perspiring rather freely at the time, and happened quite unsuspectingly to brush my face with the large overhanging fronds; in a few seconds my face was smarting so acutely that for quite an hour I could scarcely open my eyes, after which the pain went gradually. A few days later in my hurry I unthinkingly did the same thing again, with similar results, which quite convinced me as to the peculiar nature of the plant under notice. Since that time, when watering or working in the vicinity of the Davallia, I always keep my face at a distance from the fronds. As I was unaware beforehand that the Davallias had any poisonous properties, I was totally unprepared for the disagreeable surprise I received. I should like to know if any of the Journal readers have had a similar experience to the above. —JOURNEYMAN.

—— SUGAR FROM POTATOES.—Even as Beet sugar has to a great extent replaced Cane sugar and turned the industry upside down in the process, so, it appears, may Potato sugar eclipse Beet sugar and again upset the trade. A Dutch correspondent states in the "Westminster Gazette" that Dr. H. C Prinzen Geerlings, Director of the Proof-station in Kagok-tegal (Java), formerly of the University of Amsterdam, and many years assistant in the chemical laboratory of that University, has discovered a simple method of converting the starch of Potatoes into sugar. He has sent in a sealed envelope, as is customary, the description of his method to the French Académie des Sciences; this to secure the priority of his invention, as his discovery is not yet quite at the stage for being made public. Dr. Prinzen Geerlings has so much official business upon his hands that some months may elapse before he can prepare the discovery for publication. Starch-producing plants are much less liable to climatic influences than sugar-producing vegetables, and with regard to the sugar industry, the only question is to find the means for converting on a big scale, and at small cost, so that the method may take the place of the manufacture of sugar from Cane or Beet. If this can be done there is one of the biggest economical revolutions in sight.

—— THE ROSE OF JERICHO.—The plant commonly known as the Rose of Jericho is Anastatica hierochuntica, *L.*, and that it has borne that name for centuries is proved by the fact that it is figured and described as such by nearly all the early herbalists. Lonitzer (Lonicera), the first edition of whose "Kreuterbuch" appeared in the middle of the sixteenth century, writes of it as a well known foreign herb. bearing the names Rosen von Hiericho, Rosa Hierichuntis, Rosa S. Mariæ, and Rosa Hierosolimitana. Several other sixteenth century authors write more fully on it. But it is now claimed that Asteriscus pygmæus, *Coss. et Dur.* (Compositæ), is the true Rose of Jericho. The Abbé Michon, who accompanied De Saulcy on his travels in the East, describes ("Voyage Religieux en Orient," vol. ii., page 383) a plant under the name of Saulcya Hierochuntica, which he regarded as the true Rose of Jericho of the pilgrims of the Middle Ages, because it is introduced into the arms of several French noble families. Boissier ("Flora Orientalis," iii., page 179) identified Saulcya with Asteriscus, and cites Michon's opinion as to its being the true Rose of Jericho. Here the matter rested apparently until 1882, when Dr. P. Ascherson brought the subject before the Botanischen Vereins der Provinz Brandenburg ("Verhandlungen," xxiii., page 44). More recently (1886) Dr. G. Schweinfurth has written on "La Vraie Rose de Jericho" ("Bull. de l'Inst. Egypt.," 2me séries, n. 6, pages 92–96), where, according to Just ("Bot. Jahresber.," 1886, 2, page 196), he recognises Asteriscus pygmæus as the plant. This covers a wider geographical area than the Anastatica, ranging from Algeria to Baluchistan, and it is very abundant in the neighbourhood of Jericho. In Asteriscus it is the involucral leaves especially that are hygroscopic, being closely incurved over the fruit in a dry state, and quickly opening out to an almost horizontal position under the influence of moisture.—("Kew Bulletin.")

—— THE DEVON AND EXETER GARDENERS' ASSOCIATION.—The autumn programme of this Society, which holds its meetings in the Council Chamber of the Guildhall, Exeter, on Wednesdays at eight o'clock prompt, is as follows:—October 13th, Mr. J. Mayne, Bicton, "The Qualifications and Duties of a Gardener." October 27th, Mr. R. Hodder, Ponsonby, Torquay, "How a Knowledge of Botany is a Help to Gardening." November 10th, Mr. T. H. Slade, Poltimore Park, "Pruning and the General Management of Fruit Trees." November 24th, Mr. W. Andrews, Elmfield, Exeter, "Herbs: Their Cultivation and their Uses." December 8th, Mr. G. Camp, Culver Gardens, Exeter, "Winter-flowering and Foliage Begonias." December 22nd, Papers by the juniors.

—— DAMSONS.- I paid 4d. per lb. for these fruits in one of our Kingston shops recently, apparently Farleigh Prolific. That is a price to make one's mouth to water, and how much growers would like to get one-half. As good Damsons range to about 60 lbs. per bushel, the price is 20s. for the latter quantity. It would be interesting to learn what Damsons are just now really fetching in the market, but certainly a long way below 20s. The disproportion between growers' wholesale and consumers' retail prices is out of all reason. No wonder we have what are termed gluts in some seasons, as it is impossible for the grower to get to the million the full benefit of his abundant crops. Our method of trading is so complicated that not one only, but half a dozen persons, must have their profits out of an article.—A. D.

—— FUCHSIAS AT EGHAM.—Several weeks since there was a complimentary note made in the *Journal of Horticulture* in reference to the remarkable display of Fuchsias and other plants which Mr. H. Paice, C.C., the well-known corn merchant, makes in his roadside garden in Egham. I passed that garden but a few days since, and was surprised to see how wonderfully the Fuchsias were still blooming. The arch of these plants leading from gate to door of house, a most unusual feature everywhere else, but seen here every summer, was a veritable bower of drooping flowers. The tall standards, that are some 6 to 8 feet in height, were blooming profusely still, so also were dwarfer ones, and also were standard Heliotropes. Some tall bushes of Calceolaria amplexicaulis, so very showy and effective grown on in this way from year to year, were blooming finely. Mr. Paice has indeed a remarkable front garden, and it is a distinct attraction to this ancient Surrey town.—WANDERER.

—— CAMPHOR CULTURE.—An account of the range, cultivation, uses, and products of the Camphor tree (Cinnamomum camphora) is given in a circular (No. 12) just distributed by the U.S. Department of Agriculture (Division of Botany). Notwithstanding the comparatively narrow limits of its natural environment, the Camphor tree grows well in cultivation under widely different conditions. It has become abundantly naturalised in Madagascar. It flourishes at Buenos Ayres. It thrives in Egypt, in the Canary Islands, in South-Eastern France, and in the San Joaquin Valley in California, where the summers are hot and dry. Large trees, at least 200 years old, are growing in the temple courts at Tokyo, where they are subject to a winter of seventy to eighty nights of frost, with an occasional minimum temperature as low as 12° to 16° Fahr. The conditions for really successful cultivation appear to be a minimum winter temperature not below 20° Fahr., 50 inches or more of rain during the warm growing season, and an abundance of plant food, rich in nitrogen. In the native forests in Formosa, Fukien, and Japan camphor is distilled almost exclusively from the wood of the trunks, roots, and larger branches. The work is performed by hand labour, and the methods employed seem rather crude. The Camphor trees are felled, and the trunk, larger limbs, and sometimes the roots, are cut into chips, which are placed in a wooden tub about 40 inches high and 20 inches in diameter at the base, tapering towards the top like an old-fashioned churn. The tub has a tight-fitting cover, which may be removed to put in the chips. A Bamboo tube extends from near the top of the tub into the condenser. This consists of two wooden tubs of different sizes, the larger one right side up, kept about two-thirds full of water from a continuous stream, which runs out of a hole in one side. The smaller one is inverted, with its edges below the water, forming an air-tight chamber. This air chamber is kept cool by the water falling on the top and running down over the sides. The upper part of the air chamber is sometimes filled with clean Rice straw, on which the camphor crystallises, while the oil drips down and collects on the surface of the water. In some cases the camphor and oil are allowed to collect together on the surface of the water, and are afterwards separated by filtration through Rice straw or by pressure. About twelve hours are required for distilling a tubful by this method. Then the chips are removed and dried for use in the furnace, and a new charge is put in. At the same time the camphor and oil are removed from the condenser. By this method 20 to 40 lbs. of chips are required for 1 lb. of crude camphor.—("Nature.")

THE MOSS ROSE.

How strangely Moss Roses have gone out of fashion. One meets them occasionally in cottage gardens, and in grander Rose gardens looking rather ashamed, poked into some corner probably, which the Upper Ten despise; but it is very rare to see a bed of them. And yet how distinct they are; how striking in foliage, especially the Crested Moss; above all, how fragrant! Here we have the true Provence odour. Now that garden Roses are shown, there is just a chance of their being recognised; there would be a far greater if the N.R.S. Committee would but decree a prize for them. I count fourteen varieties in the last Cheshunt catalogue. Surely that would enable a good box of "six distinct!"

It is one of our oldest Roses. Rivers tells us, in his excellent account of early Roses, that the Old Double Moss came here from Holland in 1596. He considers it "an accidental sport, or seminal variety, of the common Provence Rose"—the good old Cabbage, the Rosa centifolia. An interesting notice, in a recent number of "our Journal," gives its mythical origin, telling this in the pleasing form of an Eastern legend.

This has also been rehearsed in verses, the author of which I have never been able to discover; they are lines, I have always thought, of a high degree of merit.

The Angel of the Flowers one day
Beneath a Rose bush sleeping lay—
That Spirit to whom charge is giveu
To bathe young buds in dews from heaven.

Awaking from his light repose,
The Angel whispered to the Rose:
"Thou loveliest object of my care,
Still fairest found where all are fair,
In the sweet sleep thou'st given me
Ask what thou wilt—'tis granted thee!"

Then said the Rose, with deeper glow,
"On me another grace bestow!"
The Angel paused, in silent thought;
"What grace is there this flower has not?"

'Twas but a moment: o'er the Rose
A veil of moss the Angel throws.
Thus robed in Nature's simplest weed,
Can there a flower that Rose exceed?

—A. C.

GARDEN ROSES.

IN addition to the selection of garden Roses which was given on page 272, the following must be given. These, with those previously noted, may be taken as amongst the very best, though some have possibly been omitted whose beauty justifies their having a place.

HOMER.—A charming variety, which is blush, edged with deep rose. It is suitable for a low wall.

L'IDEAL.—Everyone knows the yellow and metallic red, shaded, streaked, and tinted golden yellow flowers of this exceedingly pretty and distinct variety.

MADAME PLANTIER.—Pure white, and flowering freely in clusters. This is very useful.

WILLIAM ALLEN RICHARDSON.—This is now too well known to require further description. It is undoubtedly one of the best of garden Roses for bushes, hedges, walls, or trellises. The deep orange yellow petals make a charming display.

MADAME CARNOT.—A charming seedling from the above. The colour is golden yellow, deeper in the centre, with a coppery edge.

ALLISTER STELLA GRAY.—Producing flowers in clusters like a Noisette, this is a favourite with many. It is somewhat similar to W. A. Richardson, but smaller, and quite distinct. It is a strong grower, and a desirable acquisition for pillars, or wherever a climbing Rose is wanted.

CARMINE PILLAR.—A new single flowering variety. The colour is vivid rosy carmine. The plant is profuse in blooming, and of strong growth.

DUKE OF YORK.—Belonging to the China section, this Rose is of much merit. In colour it is bright pink, shading to rosy scarlet. Sometimes the petals are edged and tipped white. The fragrant blooms are very freely produced.

DOMETIL BOCCARD.—One of the prettiest striped Roses in cultivation. Flesh white, with bright rose and lilac stripes, is the colour.

FÉLICITÉ PERPETUÉ.—This creamy white Rose is well known. It flowers in clusters, and is a charming evergreen variety.

MARQUIS OF SALISBURY.—The semi-double rich crimson flowers of this Rose are constantly produced. It is certainly one of the best.

MADAME PERNET DUCHER.—A most popular variety of a canary yellow, lightly tinted with cream colour. It is exceedingly beautiful in the bud.

TUSCANY.—Flowering in the summer, the deep crimson semi-double blooms are most brilliant. They are frequently 6 to 8 inches in diameter.

YORK AND LANCASTER.—No collection of garden Roses could be complete without this fine old variety. It is striped white and red. Occasionally all red or all white blooms are produced.

ANNA MARIA DE MONTRAVEL.—Very diminutive flowers of the purest white. A perfect Fairy Rose, finely perfumed.

GLOIRE DE POLYANTHA.—The colour of this is deep rose with a white base to the tiny petals.

JANET'S PRIDE.—A semi-double variety. White shaded and edged crimson lake, and striped light crimson.

CAMOENS.—One of the best. It is glowing rose colour, with yellow at the base of the petals. The buds are long and pointed, and it is very free flowering in the autumn.

DR. GRILL.—Rose coloured, with coppery shading; one of the best bedders.

MA CAPUCINE.—Buff and bright orange, charming with its small miniature buds.

MACRANTHA.—This is one of the finest single Roses in cultivation. Pure white with golden stamens, large and bold blooms.

MACARTNEY SIMPLE.—A large pure white variety with evergreen shining foliage.

RUGOSA.—Single carmine-crimson flowers, which are succeeded in autumn by bunches of large berries of rich coral-red colour.

RUBRIFOLIA.—This produces small dark red flowers, glaucous foliage. The leaflets are tinged with red.

Lord Penzance's Briars are extremely useful in the garden, and are destined to become great favourites. The variety of colouring, freedom of flowering, combined with their sweetness of perfume, cannot fail to make them popular when they become cheaper. Amongst the best are Rose Bradwardine, clear rose; Meg Merrilies, gorgeous crimson; Lucy Ashton, white, with pink edges; Lord Penzance, soft shade of fawn, passing to emerald yellow in the centre; Lady Penzance, a soft tint of copper, the base of each petal bright yellow; Flora M'Ivor, pure white, blushed with rose; Brenda, Maiden's Blush or Peach, and Catherine Seyton, soft rose pink with bright golden anthers.—E. MOLYNEUX.

HYDRANGEA PANICULATA.

THE sterile variety of this Hydrangea is perhaps better known than the type, and for all garden purposes it is without doubt the best. It is interesting, however, to grow the typical plant and the variety H. paniculata grandiflora, or, as it is now called in the "Kew Hand List of Trees and Shrubs," H. paniculata hortensis, side by side. The type will be found to be well worth growing, and is interesting to show at a glance the great difference between the two.

Growing under the same conditions the foliage of the typical plant will be found to be much better than that of the variety. In the former case the leaves range up to 9 inches in length, while those of the variety rarely exceed 7 inches. With the inflorescence the case is quite different, as that of the variety is larger in every way. The size of the flowers is determined by cultivation. A large bed near the Pagoda at Kew is planted with the type and variety, and they are there cultivated to a high degree.

This year the inflorescences of the type have been from 9 inches to 1 foot in length by 8 inches at the base, while many of those of the variety have been 1½ foot in length by a foot in width at the base. The bed was made up originally with good clayey loam, decayed leaves and cowdung, and has since been regularly top-dressed. The plants are pruned hard in spring, and the young growths are afterwards reduced to four, five, or six, according to the strength of the plant.—D.

ENDIVE AND LETTUCE FOR WINTER.

MANY modes of protecting these valuable salads during the winter months are adopted. Any old frames or pits will answer the purpose provided the roof glass is in good condition. This is a most important point, for if the lights are out of repair the rains will not be carried off, but will drip through on to the plants, which is most injurious to the occupants. The structures should be in some sheltered part of the garden, and must have a good depth of drainage beneath the sod, and a good layer of rough litter or leaves placed thereon, the latter to be well trodden to prevent the soil from running amongst the drainage. On this ought to be placed about 1 foot of soil, which must not be too rich, or the plants will grow too rapidly, and become more liable to injury by frost. On the other hand, the soil must not be poor or the plants will be stunted in growth, and become hard and tough, instead of being crisp and tender.

If the plants are ready to be lifted, the seeds having been sown about the first or second week in August, and have been transplanted from the seed bed on to a warm border, they can be carefully placed in their winter quarters. After planting they should be well watered, and be shaded from bright sunshine for a few days. After this gradually inure them to all the light and air possible; in fact the lights should be entirely removed, only replacing in frosty weather, or if rainy weather prevails. In the latter case the lights should be tilted back and front to admit abundance of air. Avoid planting too thickly; each one should be clear of its neighbour, otherwise they will be liable to damp.

Cultivators in the South may also secure a supply up to Christmas, or even later, by planting some out at the foot of a south wall. This is a decided advantage, as then it is not necessary to plant such a large quantity under glass. Various methods of blanching Endive are adopted—1, By placing inverted flower pots over the plants, and covering the hole at the bottom with a piece of slate; 2, by tying up with bass, which should always be performed when the plants are dry; and 3, by covering the whole plant with a common tile.—H. T. M.

HALTON.

A SIMPLE heading for an article is this, but it is one which is, from the horticultural aspect, instinct with material for the penman. All phases of gardening are carried out at Halton on a very wide scale—indeed, in some departments it somewhat resembles a market growing establishment, so enormous are its stocks of plants. The maintenance of such an estate in the best possible style is worthy the reputation of its owner, Alfred de Rothschild, Esq., whose interest in horticultural and kindred subjects is well known and appreciated by gardeners. This interest, it may be added, is not confined to this one member of the family, for Lord de Rothschild, of Tring; Baron Ferdinand de Rothschild, of Waddesden Manor; and Leopold de Rothschild, Esq., of Ascott, are also supporters of the craft. For confirmation of this one has but to visit the gardens of either of the residences mentioned, for each is distinguished for its excellences in some one or other department.

But beyond this these gentlemen to show how friendly they are to horticulture and horticulturists, and though not strictly in place in a few notes on Halton, the reference will, we hope, be pardoned. It is to their connection with the Gardeners' Royal Benevolent Institution that we would refer. For years their support has been constant, and has been afforded with that absence of ostentation which renders the most graceful act more graceful still. Now it is good news to know that the Hon. Walter de Rothschild has taken the trusteeship rendered vacant by the death of Dr. Hogg, while Lord de Rothschild is a vice-president of the Institution. They are men of wealth, but what is often even more important to a society of this nature, they are men of business, and their judgment of financial matters will be of the utmost value. The Society, largely owing to the untiring efforts of Mr. Harry J. Veitch and Mr. G. J. Ingram, has always been prosperous, but we hope that the Jubilee year will be the dawn of new era of greater brightness and wider usefulness than any the past has seen. Gardeners ought to know their duty in this direction, for they have been shown the Institution's usefulness times without number, but it is to be feared they do not all do it as it should be done.

But we must return to our proper subject now or we shall inevitably miss much that is worthy of being chronicled in the pages of the Journal. It is not the first time, nor, it is hoped, will it be the last, that references have been made to this beautiful home, but too much can never be said in the limits of two or three columns of type about such a garden. Then, with the aid of the camera, we can present different features that the pen could never paint, even in the most skilful hand—but of these pictures more will be said a little later, when in fact we reach them on our tour of inspection with Mr. R. C. Sanders, the gardener in chief. A quiet, unassuming man is our guide, but a thorough gardener. He has a responsible charge, and he looks after it to the best of his ability, and only a cursory glance is needed to show that his knowledge and perseverance are of the highest. Every possible thing seems to be done that will tend to the credit of the gentleman by whom he is employed, to the estate, or to himself.

On the occasion of a previous visit to Halton the journey was made *viâ* Euston and Tring, but acting on Mr. Sanders' advice the Baker Street and Wendover route was chosen this time. The change was a pleasant one, the earlier portion being interesting by reason of the laying of the new Central Railway, while further on some charming country was passed, affording fine views over hills and through fertile valleys. Detraining at Wendover, we found our host waiting, and were quickly making our way to our destination, not by the nearest road, but by one which took us over and round the hills. The major portion of the distance was traversed on the grass drives that are so abundant on the estate, and through the woods, with which the hill sides are clad. Magnificent vistas were enjoyed through the trees every now and again, one of them showing the mansion of Halton lying many scores of feet beneath. From there the house looked very handsome, and was apparently quite in a valley, but later in the day, when we were on the main road, a glimpse proved to us that it stood many feet above the normal level.

But the finest view obtained was one from a broad table land, overlooking the Vale of Aylesbury, with its fertile fields and winding streams. On the one hand was the town of Aylesbury, while on the other Tring could be seen, both several miles away. Carrying the eye right beyond the valley to the range of hills we could see the mansion of Waddesden, just the smallest bit of Mentmore and the position of Ascott was pointed out as in a big clump of trees. It was a most beautiful scene, at least for those eyes that admire the simple beauty of Nature. There were no rugged features observable—the panorama was one of trees, fields, streams, homesteads, here in clusters and there standing alone, with the towns named above, several churches, and on every side hills, which may as a whole be described as essentially English. The hill on which we stood was of chalk, which could be seen glistening through its crust of soil; in the valley, and occasionally on the hills, it was noticeable that the ground was of a different and far more fertile character. There was a descent by grass drives, but we chose a fresh road that took us outside the gates to re-enter again near the mansion.

On entering the park there was a notable change in the character of the surroundings. Here the trees and shrubs looked to have been better tended, and were growing in more congenial soil. Without the herbage in places had been scant, though in others it was singularly luxuriant. No pause was made now at the mansion, but our course was continued until the gardens were reached, where we alighted to perform the remainder of our tour on foot. Quickly making our way to the gardens, we were passing through house after house filled to overflowing with thousands of plants of almost all kinds and sizes such as are useful for house decoration. None was very large, such not being required, but all were healthy. However, we may give a brief paragraph to each of the departments ere turning to the pleasure grounds, the Italian garden, and the conservatory.

The number of plants grown in 6-inch and smaller pots is nothing short of stupendous, house after house being completely filled with them. Thousands of Crotons in a small state are to be seen, and as they are all young they have a pleasing fresh appearance, while the colour development is remarkable. Immediately one of these is observed to be past its best the top is taken off and inserted in cocoa-nut fibre refuse in a warm propagating pit, where new roots are quickly emitted and a young plant soon formed. Dracænas, especially Lindeni, are largely utilised for the same purpose, as are Caladiums, of which the collection is very fine. It is a matter for regret that these plants with their chastely hued and delicately veined leaves do not last longer in good condition when employed for decoration. Many of the Palms are much larger, but there are very few of any considerable size. Ferns, of course, come in for a goodly share of attention, for their graceful fronds could scarcely be dispensed with. There are other foliage plants, but these form the bulk of the stock, and the names of the others will readily occur to readers.

When mention is made of flowering plants under glass the place of honour must be accorded to the Carnations, of which something approaching 6000 are grown in pots. These comprise perpetual flowering varieties largely: but, as is well known, Malmaisons are by no means neglected. Unfortunately, these have the disease amongst them, and Mr. Sanders is wisely reducing the stock with a view to a fresh start with clean plants. The healthy condition of the others, both in houses and frames, is very marked indeed, and it is almost superfluous to say that flowers are always to be had. Brightly coloured varieties largely preponderate, as these are the favourites with Mr. Rothschild, whose admiration for Carnations is very decided. Anthuriums, with their scarlet spathes, are popular at Halton, and claim a large amount of space in the houses. Their showiness insures them a welcome in such bold and effective decorations as are carried out. Cannas, again, are there in numbers, as are many other plants of which specific mention need not be made.

Out of doors in the gardens in which the glass structures are situated there are many borders, and a few beds to be seen occupied with hardy flowers of much beauty. There are Gladioli, Asters, Sweet Peas, Zinnias, with several others that are useful for cutting. One of the most charming borders was a narrow one at the side of a house, it being full of Belladonna Lilies flowering superbly. Chrysanthemums must of course have a place, and that they are well grown is proved by their present condition. There are many of the dwarf early varieties in pots in flower in the houses, but of course the major portion of the plants are cultivated for later use, and were stood on a border outdoors when this visit was paid, presenting a handsome appearance. The wood and foliage were clean and healthy.

Though all kinds of fruits are to be seen under glass—that is to say, all that are commonly cultivated under these conditions, Figs and Cherries are the only two for which the owner has any decided partiality. Such being the case, the seasons of these are extended to the utmost, and of the former there are fruits during the majority of the months of the year. The conditions are not of the most favourable, but the results are very praiseworthy. The Cherry house is occupied with rather old trees trained on trellises beneath the roof glass on each side of a span-roofed structure, and these by careful attention annually produce splendid crops of fruit. Peaches and Nectarines, with Grapes and Melons, are all to be seen. The vineries are being thoroughly renovated in turn, new borders are to be formed for the reception of the roots, and it is confidently anticipated that in the course of a few years the Grapes will be better in appearance as well as in quality than they have for some years past. Although Tomatoes and Cucumbers are not usually considered under the head of fruits, they are now thus briefly referred to ere we turn our thoughts to the several things that have yet to be seen out of doors.

The large vegetable garden, with its broad grass walks, is extremely interesting to anyone with a predilection towards the examination of good

vegetables. Though of considerable size, almost every bit of ground is utilised to its utmost capacity, and the breadths of Asparagus, the various green and tap-rooted vegetables, Potatoes and Onions, are immense. Moreover, the whole of them are in capital condition – not large, but small to medium-sized, such as usually give the best quality. Then there are no weeds to be seen, so that the crops have the benefit of the food that the soil contains. In the enrichment of the ground, which varies according to the crop that is to be put in, both natural and artificial manures are employed. The fruit trees, which are numerous in this portion of the garden, are in splendid health, and, generally speaking, are carrying fair crops of fruit, though some trees are lighter than usual. Bush fruits are also largely grown. Wall fruit cannot be termed a particular feature at Halton, owing to the small lengths of wall available. Where fruits are grown thereon, they are in fine condition, and produce good crops.

We may now wend our way to the pleasure grounds about the mansion. These are charmingly diversified by the aid of trees, shrubs, undulating lawns, large borders, immense beds, with a lake of some considerable size. Around this is a broad grass drive broken here and there by shrubs

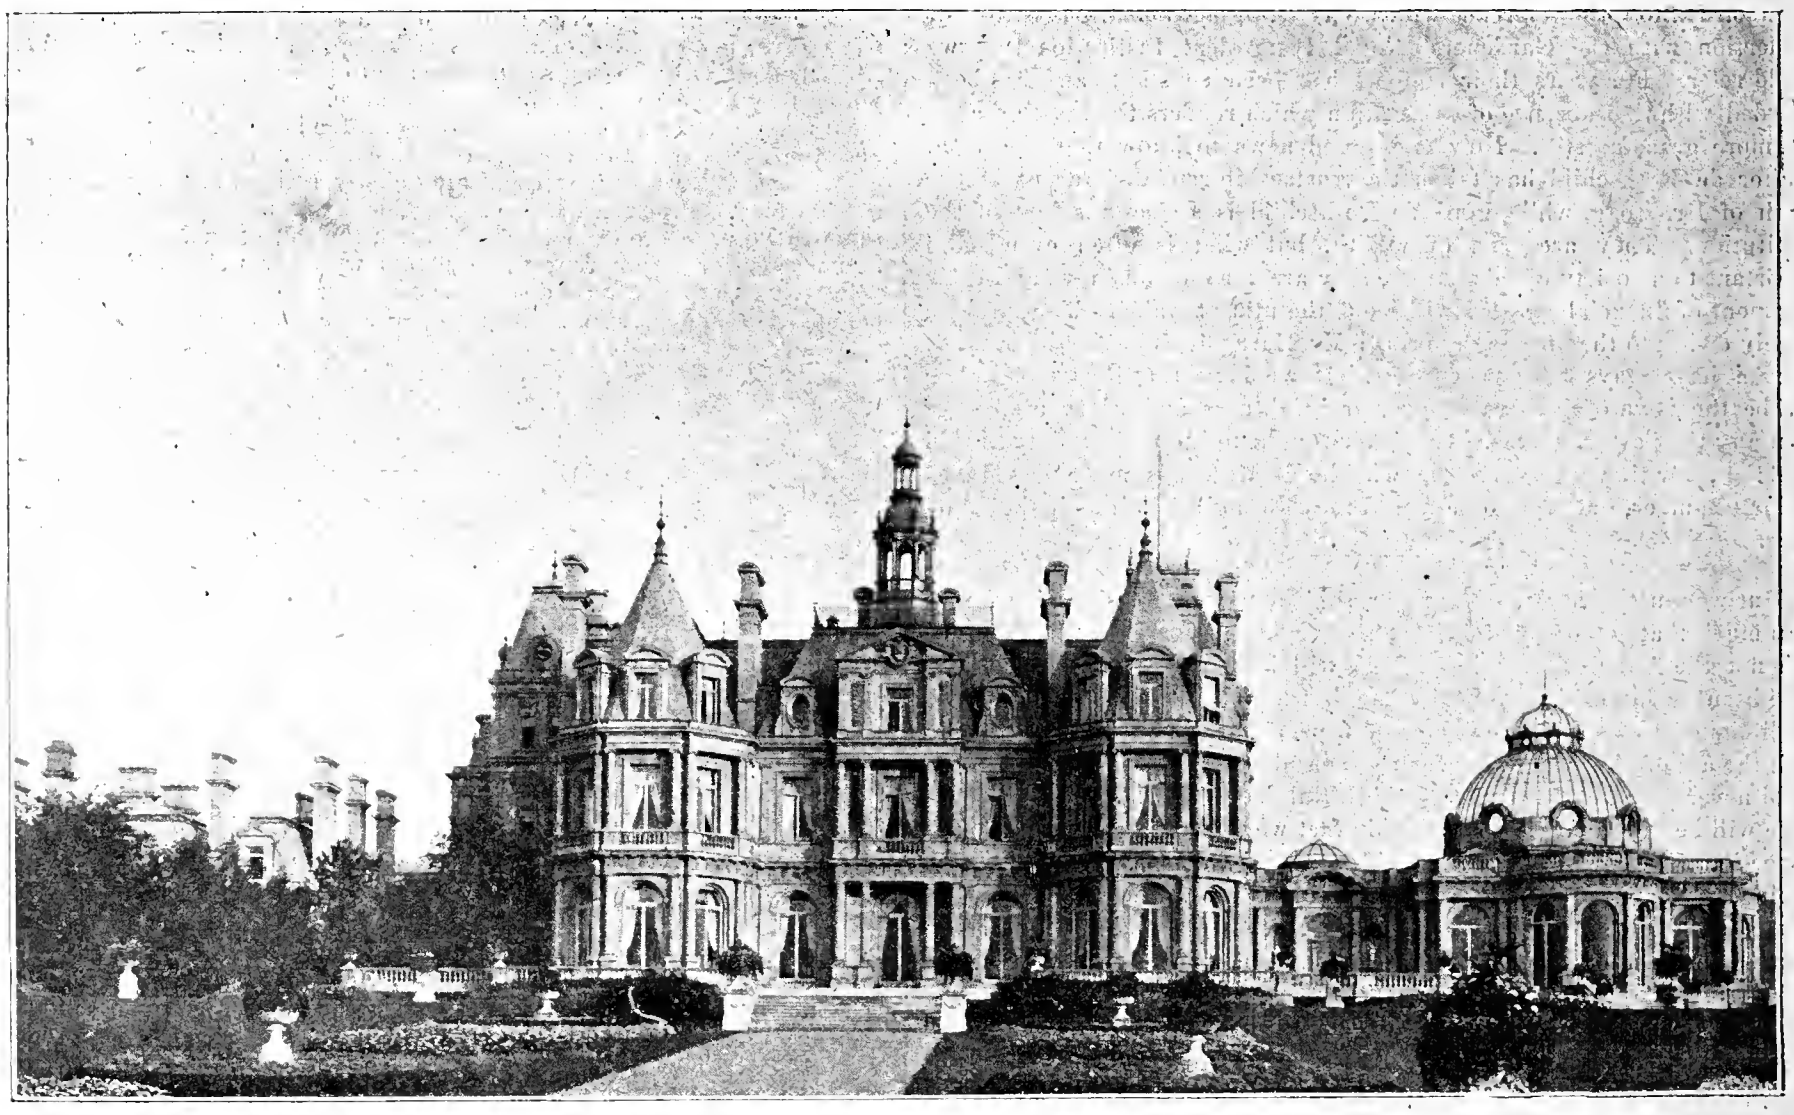

FIG. 47.—HALTON HOUSE.

or beds, and backed by shrubberies of great extent. At the head of the lake is a pleasant summer house ; indeed these structures are to be met with frequently all over the estate. Scores of fantail pigeons find a home in a cote near, and look very pretty strutting about the soft green grass or drinking from the lake. The area of grass that has to be mown is very large, and as some of the borders are narrow the work occupies several hands and many machines to keep it in the excellent condition that is so much desired. Something is constantly being done on it, and must be, or it would soon present an untidy appearance. A circular concrete bicycle track has been laid down close to the mansion, and looks rather peculiar in the turf at the first glance.

The flower gardens in contiguity to the mansion are brilliantly beautiful now, and have been for some considerable time. On each side of the path leading to the entrance of the house, and clearly shown in the photographic illustration (fig. 47), there are circular beds, while diverging on each side of the door along a terrace walk are beds of varying designs. Standing on this terrace the picture is one of singular beauty, though the planting is without exception of the simplest. One bed will be filled with Zonal Pelargoniums of one colour, and a second with another, the same practice being adopted with Begonias and Fuchsias ; occasional "dot" plants being used in some of them. Each bed contains a stone vase, and these, again, are planted in some simple yet effective manner. Handsome as are all the beds, the two, one on each side at the top of the walk on the terrace, are superior to all the others. Both are planted with a dwarf crimson-scarlet double tuberous-rooted Begonia named Lafayette, which for floriferousness and effectiveness, is, so far as I am aware, unrivalled. They are sheets of brilliance such as one seldom sees, but which are always certain of admiration.

In another portion of the garden a different style of planting is adopted. It is known as the German system of bedding, and appears to consist mainly in several bold masses of plants in one bed of immense size. It is a pleasing change from the ordinary styles of bedding, but such as I imagine one would quickly tire if much were seen. Then there is the Indian garden, with its Palms, Dracænas, and other plants that lend a sub-tropical tone, the whole being accentuated by the Indian tent which has been erected. The Italian garden was next visited, with its beautiful statues in porphyry and marble, encircled in an Ivy-clad wall. The centre grass plot contains only one large bed of mixed plants, and the formality is maintained throughout. The walk round is of mosaics on marble kerbs, and the steps are also of marble. It is pleasant to see, but one cannot but feel thankful that such is not the style of English gardening in this nineteenth century.

Everything is grand at Halton, and of all the conservatory shown to the right of fig 47 is the most imposing. The dome-like roof seen in the illustration is very lofty, and the stone pillars that rise for its support are handsome. Take another, and this time an interior view, from the corridor right across the circular conservatory. This is admirably depicted in fig. 48, which shows the main features as they may be seen by anyone emerging from the mansion into the corridor. No need to tell here of the Palms, the Ferns, the Bamboos, and other plants that grow therein, for the photographer has placed everything before us as plainly almost as life. The whole of the conservatory is lighted by electricity, and several lights are concentrated on the statue shown in the picture. When these are on, the effect, according to Mr. Sanders, is superb, and we can well believe him, while we are sure others will do so too. As is the case with the path in the Italian garden, the floor is of mosaic and the kerbs of marble.

Time and space are both exhausted, and of necessity the end must come now. The look through Halton has been a cursory one, and brief allusions have only been given where longer ones were deserved and called for, but they must suffice for the present. In conclusion we would testify to the cleanliness of the whole of the gardens, and to the kindness of Mr. and Mrs. Sanders. In justice we must add that the superb photographs from which our illustrations were prepared were taken by Messrs. S. G. Payne & Son of Aylesbury, on whom they reflect the highest credit.—H. J. WRIGHT.

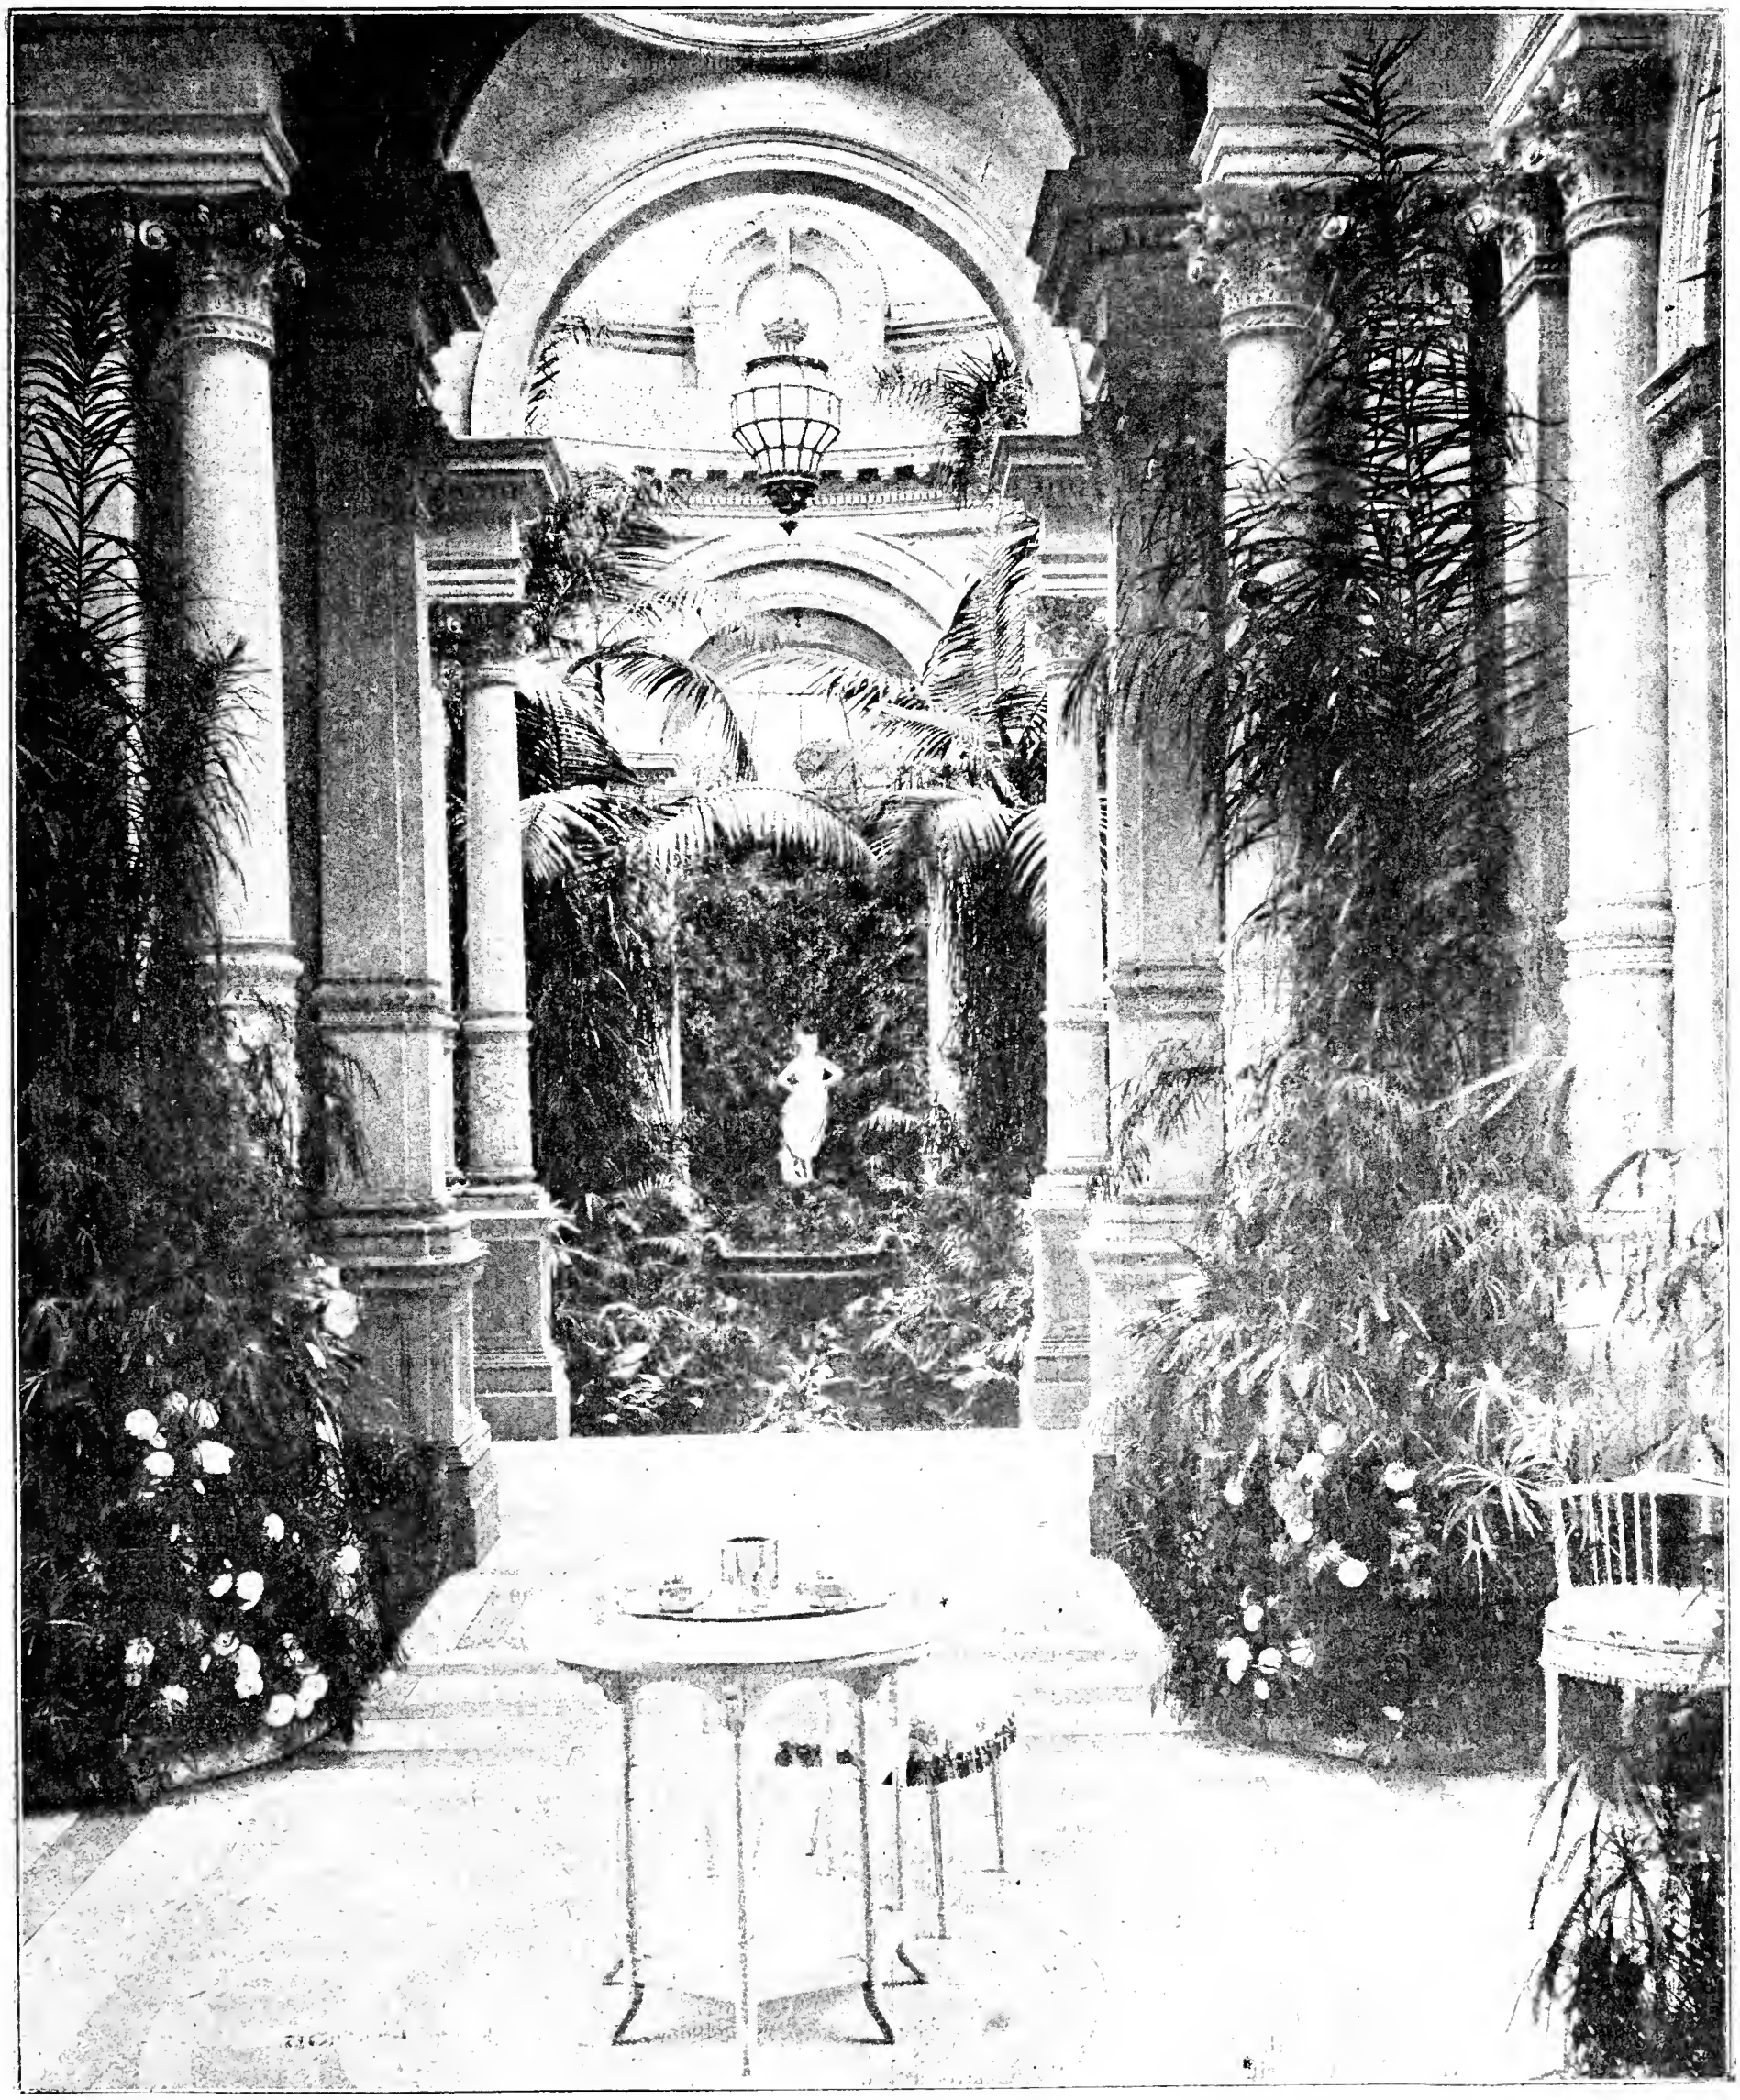

FIG. 48.—THE INTERIOR OF HALTON CONSERVATORY.

FERNS IN BASKETS.

If hanging baskets are useful accessories to the ornamentation of the cool fernery, they are just as much needed in the warm house devoted to the cultivation of Ferns and other foliage plants; but in this we have less difficulty to contend with, as there is a far larger quantity of plants from which a varied selection can be made; and on account of the great diversity found among stove Ferns, both as regards colour and form, a much greater variation may be obtained through the planting of these hanging baskets in various sizes.

Ferns for Small Baskets.

Exceedingly pretty little baskets can be filled exclusively with the Adiantums Edgeworthi, dolabriforme, and caudatum, all three evergreen East Indian species of small and rampant growth. Their being proliferous at the apex of the fronds is a great recommendation for the purpose which we have in view, as these species frequently show three, and even four, generations of plants hanging from the original or mother fronds. The general appearance of A. Edgeworthi or ciliatum, as it is sometimes called, is as distinct as it is pleasing on account of the lovely soft green tint of its pubescent foliage, as also because of the elegant way in which the pinnæ, pink in their young stage, are divided. A. caudatum is easily distinguished from the above by the greyish and dull colour of its fronds, and also by the peculiar shape of its pinnæ, which are much more cuneiform; while in A. dolabriforme we have a plant entirely distinct from the other two; and, although it appears as only a variety of the lovely A. lunulatum, it is much to be valued on account of its evergreen character, which does not belong to the species. A. dolabriforme was sent out with the idea that it would prove a plant of great value for basket culture, and the anticipation has been fully realised, for it forms a dense yet elegant mass of a particularly bright green foliage, and has been the means of making some of the prettiest small baskets that we ever had the good fortune to see.

A. lunulatum, although naturally deciduous, is well worthy of cultivation for basket purposes. This distinct and handsome species, of slender pendulous habit, has foliage of a peculiar shape, its alternate pinnæ being lunulate and of a particularly bright green colour, which forms a pleasing contrast with the shining black colour of the rachis and stalks, which are very conspicuous. Its foliage remains in good condition until about the middle of October, when it dies down naturally; and if the plant is properly treated during the winter and not allowed to get dust dry it usually starts into growth about the middle of February, or at the latest the beginning of March, and rapidly forms a most interesting mass of verdure.

Very pretty small baskets are also made with Asplenium elegantulum, an evergreen dwarf species from the Fiji Islands, which, like the above-named Adiantums, is proliferous at the apex and of a dark shining green colour; and the uncommon New Holland species called flabellifolium, which on account of its extremely slender growing nature is particularly well adapted for that purpose. Its fronds, generally from 12 to 15 inches long, are formed of two parallel rows of small and curiously fan-shaped pinnæ, of a bright dark green colour, and thoroughly distinct aspect; the apex of its fronds is also proliferous, and it is easily propagated.

Medium-sized Baskets.

The Ferns which may with advantage be used for the formation of baskets of a larger or medium size are much more numerous than those adapted for small ones, and for that purpose almost any Ferns of a drooping habit can be utilised; but the genus which supplies us with the greatest number is undoubtedly that of Davallia. The majority of these plants are provided with creeping rhizomes, which render them most valuable for such a use, as in course of time they entirely clothe the outer surface of the baskets in which they are planted and make handsome objects. Their foliage, elegant and finely cut generally, looks particularly handsome when seen from below, and being very tenacious remains a long time on the plants. In Davallia bullata we have one of the most attractive of the genus, with fronds about 10 inches long, nearly triangular in shape, and of a rich dark shining green colour, produced on creeping rhizomes, which are covered with minute scales of a bright reddish hue, accounting for the popular appellation of the Squirrel's Foot Fern. Davallia elegans and its variety dissecta from Java are also included among the most useful Ferns for basket purposes; the fronds of both species and variety are more finely cut than those of D. bullata, and produced on rhizomes of a much lighter colour. They average from 15 inches to 24 inches in length, and are quite 8 inches in width at their base. In the same way also is D. solida, whose fronds, however, are more plumose and of a brighter green colour, smooth and shining. Although several more, such as D. fijiensis, ornata, Mooreana, the beautiful tenuifolia Veitchiana, and others may be grown in hanging baskets, the above named are the most useful among the Davallias grown for baskets of medium size.

Gold and Silver Ferns.

For the same purpose most of the Gold and Silver Ferns may also be used with great effect, the more so since the farinaceous powder, which is peculiar to them, and which is their principal ornament, is seen to a greater advantage in that position than when the same plants are grown in pots. There is nothing more effective than a good plant well established in a suspended basket of the West Indies species Gymnogramma tartarea, with massive fronds fully 2 feet long and quite 8 inches wide, dark green above, but of a beautiful and very even whiteness underneath. G. pulchella, from Venezuela, is equally interesting when grown in that way, as the lemon colour which is peculiar to the inferior surface of its long, handsome, and more finely divided fronds is then shown to perfection. Gymnogramma Laucheana gigantea is the strongest of all the Golden Ferns, its fronds, of an intense yellow on the under side, being long and more gracefully arching than those of any other kind. But however beautiful all these may be when seen from below, the G. schizophylla from Jamaica and its garden variety gloriosa, although nearly deprived of either silver or golden powder, are far the best of the genus for basket culture. It is a West Indian species, the fronds of which, from 20 inches to 30 inches long, are rather slender and arching regularly on all sides. It differs from all other Gymnogrammas by having the leafy portion of its fronds, about 3 inches broad, very finely cut, and by the remarkable peculiarity, as seen in the furcation of the rachis at about two-thirds of its length, where it is proliferous, every frond producing a young plant at the point of furcation. The very elegant contour of this Fern, its moderate size and graceful habit, its delicately cut pinnules, and also its pleasing colour, render it one of the most attractive of all our stove Ferns, and one of the very best for cultivation in suspended baskets.

We must not leave the Gold and Silver Ferns without mentioning the lovely Nothochlænas, which have all the appearance of Gold and Silver Maidenhairs, but none of their comparatively delicate constitution. Nothochlæna chrysophylla, sometimes also called N. flavens, is an elegant plant with fronds about 12 inches long, greatly resembling those of an Adiantum, even to the black and almost invisible stem, peculiar to the representatives of that popular genus, but the under surface is thickly coated with a yellow powder as thick and as conspicuous as that of any Gymnogramma. N. nivea is a plant similar in growth to that just described, but silvery white instead of yellow underneath. The under side of the fronds of N. sinuata, which frequently attain 24 inches in length, is covered with very minute white woolly scales, which produce the same effect as the white powder in the other species.

In addition to the above-described Ferns a few Adiantums also make very handsome baskets of medium dimensions, principally a crested form of the common A. cuneatum called grandiceps, the fronds of which on account of the heavy tassel situated at their summit show a drooping habit of a particularly graceful character. Then there is the lovely A. amabile of Peruvian origin, with fronds from 15 inches to 24 inches long, of a beautiful pale green colour, thin and membranaceous texture, and assume more gracefully curving lines than those of any other Maidenhair. The drooping character of the plant does not exclusively belong to the fronds, but is equally shared to a similar degree by their pinnæ, which, by their position, are entirely distinct from those of any other Adiantum. On account of its elegant and pendulous habit the charming A. concinnum from the West Indies is also a beautiful object for baskets of medium size. It is only when grown in that way that the real beauty of the foliage of the Polypodium appendiculatum can be appreciated. The crimson venation in the fronds, which average about 15 inches in length, is unique, and although it colours well in any place, still the delicate and charming network becomes more vividly coloured when exposed to the full action of the light near the glass, and the effect is much more enjoyable when the foliage is seen from below.

Large Baskets.

The Ferns used for large baskets in the warm house, though not so numerous, are, however, sufficiently plentiful, and all of a very striking character. Foremost among them is the beautiful Goniophlebium subauriculatum, a native of the Malay Islands; it should be grown in every stove fernery of large dimensions where a basket can be suspended. It has no equal for elegance among all the Ferns in cultivation, its gracefully green pinnate fronds usually attaining from 6 feet to 10 feet in length. It is of very easy culture, and is not so particular as to a little sun as most Ferns are.

Among the genus Nephrolepis, which contributes largely to the Ferns adapted for baskets of considerable size, there is the superb N. davallioides furcans from the East Indies. It is a noble Fern, of robust growth, sending forth from a central tuft numerous arching fronds from 3 to 4 feet long. These differ from those of all other kinds by their furcation, which at the base is only rudimentary; but in the fertile pinnæ the furcation is twice, and even thrice, repeated at the extremities of the first division, becoming more complete towards the point of the fronds, which on account of the weight thus produced are more pendulous than those of any other Nephrolepis. The next in usefulness is N. refuscens tripinnatifida. N. davallioides and ensifolia are equally well adapted and frequently used for growing in large baskets, which they fill in a remarkably short space of time. The fronds of the former species, when fertile, are particularly handsome, as their pinnæ are then contracted and elongated, with rounded lobes on each side, and quite peculiar and elegant.

The genus Asplenium also contributes to the list of basket-growing Ferns, though A. longissimum, a species from Penang, with fronds simply pinnate, 3 feet to 4 feet long, of coriaceous texture, and of a pleasing green colour and particularly drooping habit. In A. caudatum we have a noble-growing pendulous species from the East Indies with fronds from 2 to 3 feet long, which, like those of the above species, are proliferous at their apex. These are furnished with pinnæ of a dark shining green colour, elegantly incised and unusually long, ornamented when fertile by two parallel rows of very conspicuous black sori. Microlepia hirta cristata, Phlebodium aureum, the extremely curious Aglaomorpha Meyeniana, Adiantum Williamsi, and several other kinds also make splendid specimens when grown in that way.—T.

Chrysanthemums at Stoneleigh.

I send for your inspection some Chrysanthemum foliage, taken from plants which are being grown on the large-bloom system. I think you will agree that they have ripened well, the enclosed being a fair sample. The foliage is hard and leathery, while the wood also is thoroughly ripe and exceptionally stout. "H. D.," in his remarks anent Stoneleigh in your issue August 26th, informs your readers that he thinks the plants will not ripen well, as we lie too low at Stoneleigh. Were "H. D." to visit us again now I am strongly of opinion that he would alter his opinion.—H. T. Martin, *Stoneleigh Abbey, Kenilworth.*

[The leaves sent by our correspondent, as representing the condition of those on all the plants under his charge, are excellent; indeed, they are amongst the best we have seen. They are wonderfully stout, clean, and very deep in colour. If it were wise to prophesy by leaves we should say there will be some magnificent blooms on the Stoneleigh plants.]

A Note from Ireland.

Once again the season for housing the Chrysanthemums has come. It will be later this year in Ireland than usual, the flowers in general being more backward—indeed, few that I have seen are as yet showing colour. The wet and cold of August seem to have retarded bud formation, but the weather for the past three weeks has been ideal—bright sunshine all day with heavy dews at night. Everywhere the plants look promising, though mildew has been very prevalent in our collection. We are in a very low position in the centre of the Bog of Allen, surrounded by lakes and rivers.

It is very interesting to me to watch the newer varieties swell their buds. Yellow Carnot from second crown buds is very promising, keeping the bottom foliage much better than its parent. One of the worst for losing foliage is Baron A. de Rothschild. The following new varieties have very promising buds, and will probably be seen on the exhibition board this year:—Mrs. G. W. Palmer, Royal Standard, Royal Sovereign, Mrs. C. Keyser, Madame J. Chaure, Australian Gold, Modesto, Mr. A. G. Hubbock, Mrs. D. Dewar, and M. Gustave Henry. Some plants of W. Wright seem very late, also Joseph Brookes, Mrs. R. Jones, Mrs. J. Shrimpton, and Mrs. H. Weeks, the latter pinched the first week of February, and some plants only setting their buds during the past week, although The Queen, pinched at the same time, set at the end of August. —W. T.

Seasonable Notes.

In consequence of the varying conditions under which Chrysanthemums are grown owing to the difference in the practice of cultivators and in the climatic conditions of districts, it is somewhat difficult in referring to the treatment naturally grown plants for the production of exhibition blooms should receive, to fix on a starting point. Much depends on the strength of the plants, the firmness of the wood, and the treatment they have hitherto received.

At the outset I will call attention to a matter of the greatest importance, and that is the application of a rich top-dressing. We top-dress our plants at the end of July or early in August, a space of about 2 inches being left at the final potting for this purpose. About an inch of the material to be used is placed on the surface of the pots and pressed down rather firmly, the application being made when the soil in the pots is moderately dry, so that it does not work into a paste. The mixture used for top-dressing consists of one part of loam, one part of decayed manure, a small amount of old mortar, and a sprinkling of bonemeal. For some time afterwards the plants are watered with a can, to which a rose is affixed to avoid the risk of the top-dressing being washed out of its place, or, indeed, being greatly disturbed.

Whatever feeding the plants may have had previous to this surface dressing should be continued afterwards, as the top-dressing has no immediate effect unless a fertiliser of quick action be added to it. But the addition of manure that will act rapidly I do not think absolutely necessary, although I used it previous to last year. Now if the surface material be examined about three or four weeks after the application, strong healthy roots will be found working their way through it, and when the time arrives for housing the plants the surface will be seen to be more or less covered with these healthy vigorous feeders. In my opinion nothing can be of greater assistance in the taking up of supplies of food so essential to the plants during the development of the buds than these newly formed fibrous roots. This may at first appear to have little bearing on the future treatment of the plants. I have, however, explained this to show the condition the plants must be in as regards root action.

Having, then, secured a number of newly formed rootlets for the taking up of the food, we now feed chiefly with Clay's fertiliser and Thomson's Vine manure. These we use alternately, at intervals of about eight days, but in this matter we are guided by the state of the weather. If prolonged dull wet weather sets in, the manures must be used more sparingly, so as not to cause too quick a growth, or the flower stems will be weak and the blooms lacking in substance.

The feeding is continued after the formation of the flower buds, with an occasional watering with liquid manure from the cesspool, as a change of food is, I believe, very beneficial to them. The water used is previously placed in a large tub standing in the open, fully exposed to atmospheric influences; hence it is maintained at a somewhat similar temperature to that of the soil about the roots. As a still further assistance to the plants a bag containing soot is placed in this tub. This bag is refilled with soot about once a fortnight, as the goodness is found to be washed out of the soot in about that period. The plants are fed in this way until the blooms commence to expand, when all feeding ceases, excepting when the bloom is late. Then a little sulphate of ammonia is applied. But I do not advise the use of the sulphate excepting for the purpose of assisting in bringing forward late varieties, as it tends to shorten the durability of the blooms after their expansion.

Mildew is a most troublesome disease, and generally makes its appearance with us early in September. Sometimes it attacks the plants earlier, and this season they were attacked at the end of August. My garden is situated in a low-lying spot, and consequently the Chrysanthemums are more subject to its attacks than are those grown in gardens occupying a higher and drier situation. On its first appearance every plant is dusted with flowers of sulphur, usually early in the morning when the leaves are wet with dew, as the sulphur will then adhere to the under surface. This is a very important point, as the rain cannot remove it from the under surface as it does from the upper surface. We seldom have to repeat its application, and I have not on any occasion since adopting this practice been troubled with mildew after housing the plants. Also after the plants are housed and before the blooms commence expanding we fumigate slightly two or three times to free the plants from aphis that may remain.

Late varieties are placed on the side stages of the greenhouse over the hot-water pipes, and by means of flower pots are raised as near to the glass as possible. These receive a little sulphate of ammonia twice a week, and when the solar influences are not favourable a little artificial heat must be applied. The cultivator must use his own judgment as to the time of housing his plants, taking into consideration the locality in which he resides and the state of the buds (whether late or early), and also what means at his command for coaching them. These are important points which will repay a little study, and certainly cannot be ignored by those who would achieve success in a close competition.

Having stated how our late varieties are treated, I will allude to the general collection. The earliest varieties, which require very little fire heat—*i.e.*, only sufficient to maintain a dry atmosphere, are placed in an early vinery; and those that are naturally a little later are arranged upon the centre stage of the greenhouse. All are raised as near to the glass as possible by means of planks laid on drain pipes placed in an upright position on the stage. The plants are placed on the platform thus provided, the tallest being arranged at the back and the dwarf ones towards the front. The plants nearest the front are raised by means of various sized flower pots, so that when all is complete they form a very sharp slope to the south. By this arrangement the upper growth of every plant receives a full share of light and air—a matter of great importance if good blooms are expected. Again, every bud can be seen when the cultivator is standing in front of them, so that should they require attention a plant or two can easily be removed for that purpose.

In conclusion, I should like to refer to one further important point, and that is arranging the colours on the exhibition board. I have noticed scores of stands arranged with sometimes as many as four, and even six, blooms of a bronze or other dark shade placed together. This is not as it should be, for by judicious intermingling of the light and dark shades of colour each bloom will add to the effect of its neighbour, and consequently to the attractions of the exhibition table. It may also make all the difference between a first or second place in a close competition. —D. J.

THE CHRYSANTHEMUM SEASON.

The advent of October brings us on the very threshold of the interesting period during which the ever-welcome Chrysanthemum commences its annual reign. There is reason to hope that the season will be a good one. Plants on every hand appear to be in a flourishing condition. Strong growths have been made, and where these have been thinly disposed leaves of firm substance developed, buds appearing at or near the proper time. Though the month of September has not been of the driest and warmest character, there has been an absence of devastating gales. Several periods of very wet weather have rendered the roots and soil moist without giving supplies of water for a day or two; nor could feeding with liquid manure be carried out. However, advantages lost in one way were gained in another. The foliage received a thorough washing, and plants are better for the cleansing.

Housing.

The most important work at the present time is housing the plants. Few varieties except late plants, which may be kept out some time yet, derive any advantage from a longer sojourn in the open air. What is needed is a steady progressive swelling of the buds in a continuously regular temperature. Plants which are left out must be afforded some protection during a spell of frosty nights, which, if not coming sooner, may be expected during the last three weeks of October.

It is advisable to prepare for housing in good time, so that there is no rush and hurry at the last moment. The arrangements ought to be such that plants may be taken in and placed in a position most suitable for them to occupy, in order that the buds may swell and the flowers develop without damping. Damping is frequently caused, though it may not be the only cause, by plants being placed too near the glass, especially in a

low unheated structure. Atmospheric conditions in such a house vary considerably. When sudden changes do occur, the tender tissues of the petals are injured, and the result is decay. Fungus probably takes possession, and damping is complete. The best way to avoid this is to place the plants at a reasonable distance from the glass, and to ventilate freely at first. When the flowers are opening, and there is damp dull weather at the time, apply a little fire heat, which causes the atmosphere to be brisk by counteracting the extra moisture. Always, however, admit air. On very bright and sunny mornings afford shade to well-advanced flowers, which may prevent injury.

When housing the plants, the pots should be washed and the drainage holes cleared of dirt, which might prevent the escape of superfluous water. Dead leaves on the plants, weeds, and rubbish on the soil provide a harbour for earwigs. All such ought to be cleared away. A little hint may also be worth recording, that the hollows above the upper culms or joints in Bamboo sticks are admirable hiding places, too, for the well-known earwig. Those who did not adopt the precaution of stopping up the holes will find it advantageous to do it now.

The foliage of any variety affected with mildew ought to be dusted with sulphur, as a means of checking the fungus. The Japanese variety, W. Tricker, is subject to it, so plants of that variety will almost certainly require sulphuring. After housing give water carefully. In dull weather little will be required for several days, if plants were adequately moist when conveyed in.

Continue to disbud terminal shoots, or to take late crown buds. The best results, even for decorative purposes, are to be had from one bud on a shoot of all the large-flowering varieties.

Feeding—Artificial Manures.

When outdoors showery weather is a suitable time to feed the plants with sprinklings of artificial manure, but feeding must be continued after housing, though very little the first week. Take precautions, however, not to apply those of a hot burning character, such as guano, without mixing with soil, so that active young rootlets near the surface may not be damaged.

The easily dissolved salts, such as sulphate of ammonia and nitrate of soda, ought not to be applied direct to the surface, but dissolved in water at the rate of ¼ oz. to the gallon. These are special manures, and furnish quickly in a readily available form one important element of plant food—namely, nitrogen. Both are highly stimulating, and being so, but few applications at wide intervals are necessary. The high-class general artificial manures supply most of the essential elements of plant food, and may be given more frequently to well-rooted plants.

Animal Manures.

It is a commendable plan to alternate general and special manures with solutions prepared from animal manures obtained in a fresh condition. The manures employed may include horse, cow, sheep, and fowl manure. They may be used separately or in combination, but preference ought to be given to the use of them separately. A peck of each to 30 gallons of water forms rich and sustaining food, giving first one and then another for a few days. Dilute to a safe strength, and use clear, this being best assured by tying up the manure in a coarse bag.

Soot Water.

This solution forms a clean and valuable liquid if prepared properly. Place a quantity in a canvas bag, sinking in a tub of water. When well mixed throw in a shovelful of lime. Stir well and allow to settle. A scum will appear on the surface. On removing this the water below will be of a rich, clear wine colour, due to the lime clarifying or making it clear. If too rich or strong, dilute it to the colour of beer, and apply in rotation with other liquid food. Soot water gives a deep, dark colour to the leaves, and a richer, fuller colour to the flowers. It contains nitrogen in the form of sulphate of ammonia.

After a prolonged course of weak applications of liquid, somewhat stronger doses may be given with advantage, especially to vigorous, strongly rooted plants. The last swelling and the commencement of the unfolding of the buds is a period when abundance of food should be within the reach of healthy, hungry roots, gradually reducing the supply to clear water as the flowers are becoming fully developed.—E. D. S.

ROOT-PRUNING FRUIT TREES.

When quite a beginner I was much perplexed to hear and read of gardeners pruning the roots of trees—notably fruit trees. It seemed to me a most absurd practice, because I knew a tree could not live without its roots. As I became older, however, I began to inquire into the "why and wherefore" of this subject, and learned that in supposing the practice to be bad I was entirely wrong. The necessity for root-pruning is brought about by several different causes, among them being careless or improper planting, vigorous rootstocks, and shallowness of fertile soil.

We will consider the planting first, as upon it largely depends the future of the tree. The most common mistake, probably, is planting too deeply. If this is done the roots are of necessity placed farther away from the modifying effects of the sun and air, and are consequently in greater danger of dying or remaining inactive. It is then the mischief is being contracted. While the surface roots are inactive the lower and stronger roots are pushing straight down into the subsoil. Thus the advisability of shallow planting becomes clear to every thoughtful gardener.

Too vigorous rootstocks was the next point I mentioned. It often occurs that trees are grafted on stocks much more vigorous in constitution than the scion or graft. This is done in order to make a weak growing tree more productive than it would be on its own roots or on a stock of medium strength. But it also has a tendency on shallow soils to induce sappy growth by the roots entering the subsoil, hence the need of root-pruning.

A shallow surface soil is no fault of the gardener, and it is under such conditions that root-pruning becomes a periodical necessity where satisfactory crops of fruit are desired. It is, therefore, well for us to have, if possible, a knowledge of the depth and nature of the soil as well as of the stocks and constitution of trees we are dealing with before planting largely.

Having considered what makes root-pruning necessary, let us see what results are obtained from pursuing such a course, and why it should be done at all. When does a tree require to be root-pruned, and what are the signs to go by? What is the best time of the year to do it? Which roots shall we sever? These are questions which puzzle the uninitiated. Briefly, the real object of root-pruning is to make the trees more productive of fibrous roots as near the surface as possible. These will tend to produce wood of medium strength that will mature properly and produce plenty of fruit buds instead of sappy growths, which no amount of autumn sun will mature. Of course it does not follow that every tree requires its roots checked, for it would be absurd to tamper with those of one that was bearing heavy crops of fruit annually. Rather give such a specimen help in the shape of mulchings and liquid manure. It is trees that produce nothing but long succulent growths till late autumn which indicate to a careful observer that something is wrong somewhere, and one may rest assured the mischief is at the roots.

The best time to do this work is as soon as the fruit has been gathered, as the new roots will then have time to lay hold of the fresh soil before the advent of hard weather. It is an operation which requires to be done quickly and well. Commence about 4 to 6 feet away from the bole of the tree and remove the soil with a fork to a depth of 2 to 3 feet, according to the size of the tree and depth of fertile soil. Retain all the fibrous roots, severing the thick ones with a sharp knife, always making the cut from bottom to top, so that the cut side will face downwards. After getting down to the required depth proceed to undermine the tree in the same careful manner, making a clean cut wherever it is necessary, as jagged ends will cause the roots to decay. It is important, too, that as many of the severed portions of roots as possible be removed, as if left in the ground they are favourable to the growth of fungi, which will in time attack the living roots.

Replace the soil firmly, adding to the staple a liberal quantity of good turfy loam, which will induce the formation of the root fibres so essential to a good crop of fruit. Give a mulch of half-decayed manure and the work is finished. During this time the tree must not have been allowed to flag, being freely syringed and shaded occasionally if necessary until the roots take hold of the fresh compost. A tree thus treated will in most cases be found to give entire satisfaction in after years with an ordinary share of attention.—T. P.

PREPARING SOILS.

The successful planting and establishment of hardy trees, shrubs, and plants of all kinds depends in a great measure on previous and thorough preparation of the soil. It is true there are other essential conditions—namely, the judicious preparation of the subjects to be planted. Trees and shrubs are best planted when of portable and medium size. They should be well furnished with, if possible, balls of fibrous roots, so that they do not suffer from removal. Herbaceous plants ought to be lifted, divided, and replanted with as little delay as possible. Deep and thorough disturbance of soil is only possible when there is no danger of cutting and damaging valuable roots. Hence the desirability of taking extra trouble to trench, dig, and manure before planting permanently.

Soils are of diverse character, but their preparation previous to planting may in one particular—viz., deep culture, be practically the same. Heavy soils are largely improved in mechanical condition by deep digging or trenching. Soils of medium texture have their usefulness increased. Light soils cultivated deeply are able to draw upon the subsoil for moisture when needed. Should the evaporation from the surface in hot weather be more rapid than desirable there are various methods of checking it. The chief plans resorted to are compressing the surface, mulching, and hoeing. The latter is good for all soils, as it affords facility for the free entry of oxygen from the air.

The depth of soil required by high class cultivation is 2 to 3 feet. Trenching is the most complete and effectual method of moving the soil, but there are two ways of carrying out the operation. One is the total reversal of the position of the layers of soil, the other is the moving to a similar depth, but without altering its original position. The former acts well when the whole depth of soil is of uniform quality, or can be advantageously mixed if the subsoil differs from the upper layer. It is essential to carry out the latter method when the subsoil is poor and the upper layer good. Serious mistakes have been made by neglecting to ascertain the respective quality of each. This has resulted in burying the good and fertile upper layer, and bringing to the surface the hungry poor subsoil, in which probably few plants or crops could thrive at first. The best plan is to leave such soil in its original position, but breaking it up well, mixing with it decayed manure or vegetable material.

Heavy clayey soils or heavy adhesive loamy soils are much improved

in texture if they can be roughly broken up and exposed to a whole winter's frost, snow, rain, and wind. There is nothing like the full play of natural elements for pulverising and ameliorating stubborn soils. On such it pays to defer planting for permanent occupation for a season, and give attention to thorough cultivation. Mix with the soil when breaking it down after a winter's exposure the parings and scrapings of roads and roadsides. Any gritty material is useful. Coal ashes and the contents of a smother prove useful.

Sandy soil is hot, dry, and usually deficient in quality because of its inability to retain food. Mixing with strong or clayey loam will improve it. Chalk or lime added freely and pointed in conveys to the soil an essential food it is likely to be deficient in. Cow manure is the best for a light soil, for being of a binding and moisture-holding character it rectifies the heat and dryness natural to a sandy soil.

Land gives certain indications as to its fertility or poor quality. If weeds grow luxuriantly the soil is in good heart, and only needs a minimum amount of manure and deep cultivation to fit it for the growth of vegetables, flowers, and fruit. Small and wiry weeds indicate poor soil. Such ought to have the best spade cultivation and the most liberal manuring. The manure employed for heavy adhesive soils should be of a strawy character rather than well decayed. The strawy part helps to keep the soil open because it is longer in decaying.

Ordinary soil that is fairly good, but needs enriching, should have the addition of decomposed manure and leaf soil as a means of improving it for the planting of herbaceous plants, bulbs, annuals, and biennials.

Fruit trees are not benefited by the addition of much manure to the soil previous to planting. Roses require liberally manured soil, but it ought not to be placed so as to be in contact with the roots when the trees or bushes are inserted. Shrubs and trees, both deciduous and evergreen, need a fair depth of good fertile soil intermixed with manure. For general autumn planting, the sooner digging, trenching, and manuring is carried out the better, so that the soil may become consolidated. —S., *Gravesend.*

CUNILA MARIANA.

THIS, "D. Jameson," is what is known in North America as the Dittany, which is a name that is applied to several different plants. For instance, the Dictamnus Fraxinella is so called, as also are two species of Origanum. Possibly these names have arisen from some fancied resemblance between the plants so designated; but to say the least, the similarity of the Cunila to the Dictamnus is by no means strongly marked. Cunila Mariana, of which an illustration is given in fig. 49, is a tufted dwarf hardy perennial plant included in the Mint family and related to the Monardas and Salvias, though differing materially in general appearance. The plant rarely exceeds a foot in height, and produces its small rosy purple two-lipped flowers in great profusion, in dense corymbose or cymose clusters. According to Gray this Cunila is found in the dry hills south of New York; in England it thrives in any ordinary soil not too wet, and flowers in late summer.

AUTUMN FLOWERS AT HAMPTON COURT.

DESCRIPTIONS of summer bedding in gardens or parks invariably give glowing accounts of the beauty found in every direction when written in July or August. With the advent of lower temperature, colder nights, heavy rains, and wind storms, the later portion of September often tells a different tale. Good bedding plants, or combinations of plants, should, so far as possible, have the merit of looking gay and effective up to the end of the season, indeed right up to the advent of frost. If beds become overgrown, wild, or demoralised in any way in September, especially as so many beds did last year, and again this season, then are such plants or beds of questionable value, charming as they may have been up to a certain, though very limited, period. Thus we saw this autumn, as last autumn, Zonal Pelargoniums quite demoralised early in September, and have been worthless as bedding plants ever since.

On the other hand, we saw last year, and again this, the too much despised and criticised, yet with the general public always popular, carpet or mosaic beds almost more effective under the autumn rains than earlier. These, indeed, are of their kind the successes of the season. This has been the experience at Hampton Court Gardens both with Pelargoniums and carpet beds. I went over there on the 20th purposely to see how the bedding plants had fared, and found these to be as described. A rather foolish Jubilee design worked out with diamond, crowns and monograms in one of these beds attracted so much notice that the grass for some 3 feet wide round the bed became almost bare. Probably that sort of design will not be repeated.

Single Begonias of the large-flowered section were florally the best weather plants, although it was evident that the earlier beautifu B. Worthiana, so pretty then as an edging plant, but always so heavy in a mass, was quite washed out, and all beauty had departed. Scarlet or crimson Begonias on carpets of Königa variegata—really a beautiful mass of soft silvery white when in bloom—on Sedum glaucum, and on Mesembryanthemum cordifolium variegatum, and yellow Begonias over Viola Duchess of Sutherland—here so long misnamed Mrs. Turner—were all still bright and effective, although yellow and white Begonias never stand so well as dark coloured ones do. Besides Duchess of Sutherland Violas, so singularly beautiful, the old Blue Bell, planted freely amongst Carnations, which make such poor bedders, was full of bloom, as also was Ardwell Gem, apparently here named Yellow Prince. Some few other Violas, Countess of Kintore especially, were blooming well, and fully displayed their great value as summer bedders.

Petunias and Verbenas had become wild, and almost flowerless. Fuchsias generally had lost colour and brightness, also making rather too strong growth. It is questionable whether these plants would not be best plunged in good sized pots, to check strong growth after heavy rains. Heliotropes were still fairly good. The leaves of Gladioli, amongst those Souvenir de la Malmaison, were getting brown and unsightly, but Montbretia Pottsi around them was blooming charmingly. The Gladioli should be relegated to the mixed border another year. Beds of mixed

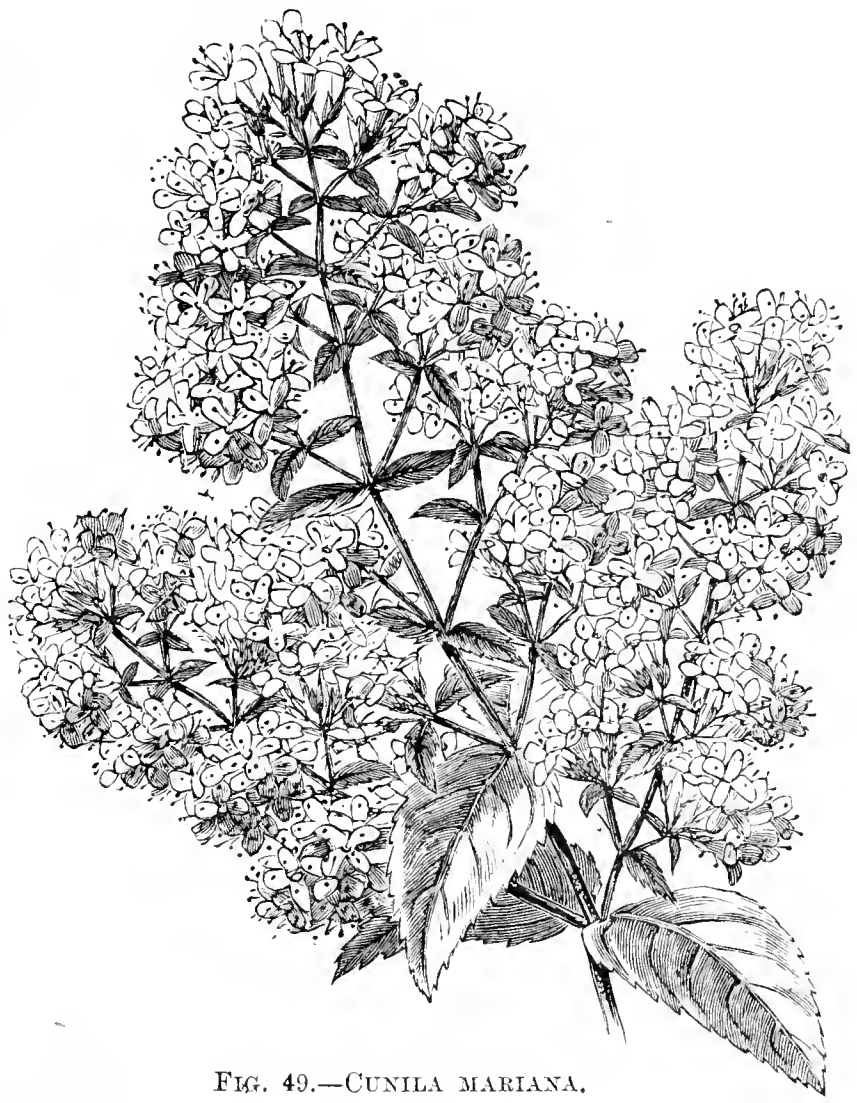

FIG. 49.—CUNILA MARIANA.

flowering and foliage plants had become overgrown, and not at all attractive; but some of the sub-tropicals, though rather dull, were, all the same, in capital form. Some large masses of bedding Dahlia Flambeau, brilliant scarlet, especially one having white Marguerites intermixed, were very effective; so also, blooming profusely, were the lemon Marguerite Etoile d'Or.

Silver variegated Pelargoniums kept fairly well, especially Flower of Spring, mixed with blue Viola and the yellow Crystal Palace Gem, dotted with Verbena venosa, was also very good. Of course edging plants of foliage form kept very well, but blue Lobelia was quite over. Lobelia cardinalis Queen Victoria and seedlings were exceedingly attractive, and gave rich colouring at this time of the year. A bed of white Begonias, dotted with the tall scarlet Lobelia, was excellent. Abutilons, too, came out well. The golden marbled Thompsoni kept wonderfully good colour, and on a bed of scarlet Begonias, set in a carpet of variegated Königa, Abutilon Souvenir de Bonn was telling, its green foliage, broadly edged with cream, telling effectively. These plants, however, generally seemed planted too formally in rows running parallel with the beds.

A bed of Lilium tigrinum, blooming freely, was rather marred by an intermixture of white Tobaccos that do not harmonise. Some dwarfer plant would have done better. A huge bed of early blooming Chrysanthemums, chiefly Madame Desgrange, because rather close under trees, had the plants tall, and both late and irregularly blooming. Tying these up also gave them a formal appearance. A broad margin in front of Aster amellus in full bloom was very effective. On the mixed borders single and Pompon Dahlias were very floriferous, and clumps of really first-rate double African Marigolds were most telling; but a large number of a wretched strain that never should be grown were horrid. These are but a few hurried notes of effective late autumn plants in these gardens. They show, in any case, that there is still much beauty in them, rough as the weather has been. That the new superintendent means to do his utmost to render the gardens attractive there can be no doubt.—A. D.

PLANTING DAFFODILS.

THERE is perhaps no better month in the year for planting the majority of Daffodils and Narcissi than early October, though some growers make a start even earlier. Such, however, are exceptions, and not the rule; indeed, amateurs have not the opportunity of proeuring their bulbs much before this date. With regard to lifting and storing them, I will only say that it is too late to attempt it if not already done, as many are already rooting freely that have not been disturbed, therefore to lift them and lose all their new roots would be a serious error. But now a few words as to planting them and their general cultivation.

Regarded collectively, the majority of Daffodils, and particularly the grand Trumpet varieties, which belong to the magni-coronatæ group, delight in a deep rich fertile loam, such as fresh turf from a pasture. In this they thrive, though it is not forthcoming in a great many instances, and they have, therefore, to be planted in something else. They are by no means a fastidious group, however, as may be gleaned from the manner in which some thrive in cottage gardens that have not been disturbed for years, where they have grown into large masses, too crowded, it may be, to flower with their wonted freedom when under good cultivation; for let it be borne in mind that while these cottage garden clumps appear to thrive, the number of flowers will be very small as compared with the number of bulbs.

Like all other plants, Daffodils cannot grow to perfection when left alone. If one of these large clumps be examined, it is most likely there may be fifty or a hundred bulbs of all sizes heaped one on another, and probably not a dozen flowering bulbs in the whole. The case is quite different with Daffodils under cultivation, when single bulbs (I allude more particularly to the old double Daffodil) will produce three, four, and even five flowers each; thus illustrating, on the one hand, the plant in a semi-wild condition, and on the other, the result of high-class cultivation. I mention these extremes to show that Daffodils, even when planted in shrubberies or semi-wild places, are much benefited by periodical lifting and separating.

SUITABLE POSITION.

The majority of Daffodils are very accommodating as to position, and may be planted in the herbaceous border proper, or fringing a plantation of Rhododendrons; on grassy slopes; in shady groves; in the woodland or wild garden, or in fact any place out of doors where a fair depth of good soil may be given them. Not the least important feature in connection with many of them is their adaptability for forcing and for pot culture under glass. Only a few years ago the rich and varying tones of gold and yellow, which are now so much admired in these Daffodils in the early spring time, were considered vulgar. Fashion and tastes quickly change, however, for who would have thought a few years ago that our common double Daffodil would ever become sufficiently popular and valuable that bouquets chiefly composed of them should figure prominently in leading West End florists' windows? Yet it is so, and extremely effective they are when arranged skilfully, and at the same time they are very enduring provided they have not been forced too hard. As pot plants in the conservatory or the drawing-room they are highly ornamental, and are being more eagerly sought after year by year.

IN POTS.

But no matter for whatever purpose they are required, whether it be for pots or for the open, no time should now be lost in obtaining supplies and having them planted at once. For pot culture the best plan to adopt is that which most growers employ for Hyacinths, Tulips, and the like, covering with a few inches of cocoa-nut fibre refuse or coal ashes. In this they will be safe for eight weeks or thereabouts, by which time abundance of roots will be formed, when they may with safety be introduced into gentle heat. The only difference I would make with Daffodils for pot culture would be to bury them completely in planting, and not, as is the case with Hyacinths, leave the apex of the bulb above the surface.

Daffodils when first introduced into heat need not occupy the stages; they may be placed beneath them, provided they are not in contact with or even near the pipes, as that would mean a serious injury to their flowering. If left plunged in the ashes a longer time than I have stated some of the earlier ones may have commenced growth, in which case they should be shaded from full light for a few days. In planting them in the open ground they are not so easily accommodated, unless it be in instances where beds are devoted to them, when the planting is simple enough.

COMPOST.

In all gardens where light sandy loam abounds Daffodils are easily accommodated, and may be planted from 4 to 6 inches deep for the larger bulbs, such as Empress and Emperor, Golden Spur, and spurius, while 2 or 3 inches deep will be ample for such as the Hoop Petticoat section and those generally of small stature. For the more delicate, such as cernuus, cernuus plenus, albicans, odorus plenus, pallidus præcox, nobilis, scoticus, and moschatus, a maximum depth of 3 inches will be sufficient; in heavy, holding, and clayey soils further precautions will be necessary in the shape of abundance of sharp grit, burnt earth, and leaf mould to render the soil as open and light as possible. The stronger varieties do not object to heavy soils provided they are well drained, in which case they are benefited by abundance of sharp sandy grit, which is not so important on lighter soils.

Another important point is that of manure for Daffodils. This is, however, a question which individuals must settle for themselves, depending as it does in its entirety on the condition of the soil. A rich fertile loam will grow Daffodils perfectly without manure of any kind, while a poor, hungry, or gravelly soil will be benefited by a dressing of cow manure worked in 3 or 4 inches below the bulbs, or failing this a good soaking of liquid manure may be given with excellent results when the roots are most active—viz., from September to end of January. The idea of supplying liquid manure in winter to these and other bulbous plants has not received the attention its importance deserves, and is probably overlooked at a season when rain or snow have made the ground sufficiently moist for most things; but not only is it highly beneficial to Daffodils and Narcissi, but to Liliums, Spanish and English Irises, tuberous Anemones, and, in fact, the majority of bulbous plants which make a number of fresh roots annually.

SELECTION OF VARIETIES.

For anyone desiring a selection of Daffodils and Narcissus to form a start, I have given the names of some of the best and most useful. Corbularia conspicuus, the golden Hoop Petticoat; princeps, yellow and sulphur, good for forcing; nobilis, sulphur and yellow, trumpet reflexed and fringed: maximus, deep golden, a fine flower; obvallaris (Tenby Daffodils), the best forcing variety of single Daffodils; Telamonius plenus, the old double Daffodil, grand for forcing; spurius, spurius major, and coronatus, all excellent for a second early batch indoors; Golden Spur, a grand flower for any purpose; Emperor, one of the grandest of all its tribe, too valuable for forcing; Horsefieldi, an exquisite flower, will force steadily; Empress, a noble flower of great merit; rugilobus, a useful variety, very free flowered; cernuus and its double form, moschatus albicans, William Goldring, cernuus pulcher, tortuosus, are all charming in the garden but not suited to growing in heated structures.

Next I would name a choice kind which is always admired—viz., pallidus præcox, a pleasing sulphur shade and most useful; then in the Incomparabile group are Stella, Glow, Cynosure, Princess Mary, and Sir Watkin, each distinct and good. Barri conspicuus is remarkable for its large spreading perianth segments of sulphur and yellow, and cup stained with orange scarlet, this is exeeedingly showy. To those named may be added poeticus ornatus, poeticus plenus, and the sulphur and orange Phœnix; poeticus ornatus is the best white forcing variety in cultivation, and its flowers by the tens of thousands find their way into Covent Garden Market from January to April inclusive. Of course such specialists as Messrs. Barr & Sons, Covent Garden, have newer varieties of the most exquisite beauty, particulars of which will be found in their catalogues.—J.

BANBURY ONION SHOW.

THIS annual Show of Mr. Deverill's took place on the 16th inst., and, as usual, proved a great attraction to the inhabitants of Banbury and district. The fine display of herbaceous flowers exhibited in bunches from Mr. Deverill's nursery made a very pleasant addition to the Show, also Dahlias, which I believe this firm has successfully exhibited for the first time this season. Probably owing to the early attack of mildew the Onions were not quite so heavy as usual in the principal classes, although Mr. Bowerman's best exhibits were not much below the average. The cottagers again showed extremely well, in fact several of their exhibits would not have disgraced any exhibition table.

Class I. is called the champion class, and is for the six largest and handsomest specimens of any variety of Deverill's Pedigree Onion. The prize is a medal or timepiece, and was well won by Mr. Bowerman of Hackwood Park, Basingstoke, with Ailsa Craig, weighing 14¾ lbs. Of this variety Mr. Bowerman seems to have a very fine strain. In the next class, for twelve specimens of either Ailsa Craig or Cocoa-nut, Mr. Bowerman was again successful with Ailsa Craig, weighing 26 lbs. clean solid bulbs. Mr. N. Kneller, Malshanger, was a close second as regards weight, but the bulbs were not so well finished as the former. Mr. Masterson, gardener to Marquis Camperdown, Weston Park, Shipston-on-Stour, was third, also showing Ailsa Craig.

For twelve specimens of either Anglo-Spanish, Lord Keeper, Royal Jubilee, or Rousham Park, the first prize was awarded to Mr. W. Keep, The Gardens, Faringdon House, Berks, who showed Rousham Park, weighing 21½ lbs.; Mr. R. Lye, Sydmonton Court, Newbury, was second with Anglo-Spanish; and Mr. Waite, Glenhurst, Esher, third with Lord Keeper. Mr. E. Thorne of Oxford was first with twelve Improved Wroxton, his exhibit weighing 12½ lbs.; Mr. Lye second. Mr. Lye was first with twelve Challenge, and Mr. Waite second.

The competition for the best single specimen of any variety of Deverill's Pedigree Onions was rather limited, but the specimen which secured Mr. Bowerman the first prize was a handsome, clean, solid Ailsa Craig, weighing 2 lbs. 13 ozs.; Mr. Kneller was second with a fine specimen of Anglo-Spanish, weighing 2 lbs. 7½ ozs.; Mr. Lye third with Ailsa Craig, weighing 2 lbs. 1 oz. For six Leeks (Deverill's Oxonian) Mr. Lye was first with clean well-blanched roots, Mr. Bowerman second, Mr. Kneller third.

In the class provided for cottagers, for twelve Onions any variety, there were twenty-four entries, and all most creditable exhibits. The first prize going to Mr. H. Ellmer of Cuckfield, Sussex, for Ailsa Craig, weighing 18¾ lbs.; Mr. Woodcroft, Neithrop, Banbury, was second with the same variety, weighing 14½ lbs.; Mr. R. Horton, Tysoe, Warwick, a close third with Ailsa Craig. Three extras were awarded in this class.

The class for eight kinds of vegetables, five to be of Deverill's specialities, brought some fine produce from Messrs. Lye and Waite, the former just gaining the first award, his Aylesbury Prize Celery and Oxonian Leeks being very good, also Autumn Giant Cauliflower and Carrots. Mr. Waite's best dishes were equally good, Autumn Giant

Cauliflower, Runner Beans (Ne Plus Ultra), Middleton Park Beet, and Exhibition Scarlet Intermediate Carrot. Mr. G. Wells, Tysoe, Warwick, was third, also showing well.

The collection of eight distinct kinds of vegetables shown by amateurs and cottagers, as before remarked, were most creditable, a great advance on any previous show. Mr. G. Wells was first with fine Runner Beans, Celery, and Cucumbers. Mr. Ellmer, Cuckfield, second, and Mr. W. Butcher, Tysoe, Warwick, third.—G. I.

THE YOUNG GARDENERS' DOMAIN.

Palms.

At the present time these plants are recognised as the most useful for house decoration, and it cannot be wondered at, for with care and attention with regard to watering and the position in which they are placed there is no limit to some of the varieties' term of duration. They are grown extensively for conservatory and decoration both in pots and planted out in beds, and large specimens have an imposing appearance.

Palms thrive best in a compost of two parts of fibrous loam, one part of peat, and one part of charcoal and sand, with a little artificial manure added. When potting they should have thoroughly good drainage, and the soil must be well rammed. The base of the plant ought never to be below the surface of the soil, but just on the level, so that when new roots are emitted they will at once enter the compost. During the spring and early summer months a somewhat high temperature is required, one ranging about 80° to 90° in the daytime with sun heat, and not to fall below 65° at night. As the summer advances, and the plants have got well established, more air may be admitted and the plants gradually hardened previous to winter.

Heavy shading is required to secure a rich green colour, also plenty of moisture both at the roots and in the atmosphere. Syringing with weak soot water will impart a dark colour to the fronds, and it may also be given them occasionally at the roots. A top-dressing of artificial manure is beneficial when the plants have plenty of root. Shading may be dispensed with about October, and during the winter months syringing will not be necessary except on bright days, and then only once, about midday. At this period very little water is required at the roots.

The varieties Latania borbonica, Chamærops excelsa, C. humilis, Livistonia rotundifolia, Corypha australis, and Thrinax elegans are strong growing, and especially adapted for conservatories. They have large fan-shaped leaves, often measuring 3 feet across. In the small state they are useful for house decorations. The Chamærops, Latania, and Corypha will stand outside in summer if they have previously been inured to the cooler temperature. Cocos flexuosa is now extensively used in corners and behind screens, where the tall handsome foliage towers above, and shows to advantage near the ceiling, unless the room is extra high. A plant in a 12-inch pot, if in good condition, should be 12 feet high.

To the Kentias falls the chief part of the work both in the house and conservatory, and when in a small state are used for table decoration. The best varieties are K. Belmoreana, K. Fosteriana, K. australis, and K. Canterburyana. Arecas are somewhat similar to the Kentias in growth and shape of foliage, and are equally well adapted for house and table decoration, but do not last quite so long. The best varieties are A. sapida, A. Baueri, and A. lutescens. Of the genus Phœnix, P. rupicola is the best, as the foliage is more graceful than the other varieties. P. dactylifera has stout erect fronds. Two other good varieties are P. sylvestris, and P. reclinata.

Seaforthia elegans and Ptychosperma Macarthuri are two tall growing varieties, with large spreading fronds. Chamædorea Wendlandi, Rhaphis flabelliformis, and R. humilis are three Palms with Reed-like stems, and are excellent for standing rough treatment. Dæmonorops plumosus, Geonoma gracilis, and Cocos Weddelliana are elegant for table decorations, the leaves being very light. They are little used for rooms, as they will only stand a short time. They also require a rather higher temperature than the other Palms.

Scale, thrip, and mealy bug are the worst enemies of Palms, and when these put in an appearance, the plants should be sponged with an insecticide.—Elveden.

Apples in Ireland.

Apples over the most part of Ireland are only a partial crop, odd trees being heavily cropped, while there are no fruits on other trees close by, though often the same variety. The varieties carrying the heaviest crop in our garden are the following:—Ribston Pippin, good on walls and trees in the open garden. Never have I seen the fruit larger or the trees growing better. The wood is clean and free from canker, the Ribston's greatest enemy here as in several other places. Alfriston is another variety having a heavy crop, many of them being of a beautiful red colour on the side next the sun, though most seasons such is entirely absent. Lord Suffield bore splendidly, the trees being now healthy and making fine growth free from canker. They suffered badly when closely pruned every year, which was the practice until the last five years. Bishop's Hero, an Apple very like Lord Suffield, which keeps till Christmas, is bearing a heavy crop of large fruit.

Bedfordshire Foundling never fails, and this year the Apples are larger than usual. It keeps till April, and is then a lovely colour. Cox's Orange Pippin is only a poor crop, most of the flowers having been blackened in the bud. Hoary Morning, Warner's King, Frogmore Prolific, Wyken Pippin, Winter Hawthornden, and several of the Codlins are all carrying good crops. Blenheim Orange is moderate, the same remark applying to King of Pippins, Cockle Pippin, Court Pendu Plat, Mère de Ménage, Stirling Castle, Peasgood's Nonesuch, and a red Apple which I imagine must be a local variety, as I have never seen it elsewhere. Lady Henniker, Gravenstein, some trees of Devonshire Quarrenden, Irish Peach, Early Madaline and Greenup's Pippin are almost failures this year.

I thought the cold wet season would have caused the fruits to be small and poorly coloured, but it is not so. We have had very fine weather for close on three weeks now, which has not only done fruit a lot of good, but also corn and hay.—W. T., *Ireland.*

Bougainvillea glabra.

When in perfect health, trained to the roof, and densely covered with its rosy or pale mauve bracts or flowers, few plants have a more striking effect than this climber. Unlike many others its season is not of short duration, but it keeps up a beautiful appearance for several weeks during the summer if not subjected to too high and moist a temperature. A warm greenhouse is probably most suitable to its culture, although it is generally grown in the stove or intermediate house.

It may be grown in pots, and trained over a balloon trellis, or in a border for covering a back wall, or training to the roof. The Bougainvillea thrives admirably in a compost of light fibrous loam, old lime rubble, with a sprinkling of coarse gritty sand, and a few half-inch bones and charcoal. When grown for training on the wall or roof it should be planted in a border about 3 feet wide and 2 feet deep, properly drained, by placing broken bricks and crocks 6 to 9 inches in thickness, with turves over the drainage to prevent it from becoming choked with loose soil. When filling the border the soil should be made firm, which to a considerable extent prevents the plant from making too gross a growth at first; and for a time after putting out the plant great care must be taken as regards the watering. But as soon as the border has got well filled with roots an abundance of water should be given with liquid manure every third time throughout the growing and flowering season.

Some people, I think, make a mistake in not pruning this plant closely enough. It is better to prune close to the old wood to one or two eyes, and in the early part of the growing season some of the young shoots may advantageously be rubbed off. The drying-off system should not be practised to the extreme, but keep the roots in a moderately moist condition throughout the winter, as is the case with Vines.

Young plants may be quickly reared from cuttings if taken off when a couple of inches long, and with a small portion of the old wood attached. These should be inserted by the side of the pot in a light sandy soil, and placed in a propagating frame. When rooted they must be at once potted, and afterwards repotted when necessary, using a somewhat lighter soil than that previously recommended for making up of the border - in fact till the plants have grown to a good size, and are in a fit state to be transferred to their permanent position.—Young Practitioner.

FRUIT FORCING.

Vines.—*Early Forced in Pots.*—This is the most advisable method of securing a supply of thin-skinned, fresh, ripe Grapes early in spring, which are a necessity in some establishments. The best varieties we have tried are White Frontignan, Foster's Seedling, Black Hamburgh, and Madresfield Court. The great evil in early forcing Vines in pots or anywhere is overcropping, the berries not attaining the size and perfection of colour and finish so essential to their high appreciation. Where bottom heat can be given to start them they will show their estimation of it, and the constant soft glow of moisture given off by the fermenting material in breaking freely. It is desirable to stand the pots on brick pedestals, placing the bricks loose and so high that the rims are slightly higher than the pit edge, the arrangement being such that the pots will be in the centre of the bed, which should be about 3½ or 4 feet wide and as much in depth. Leaves being placed in to fill the pit, a gentle warmth will be afforded the Vines, and the roots will pass from the pots into the leaves, deriving support beneficial to the health of the Vines, swelling and perfecting of the Grapes.

To have Grapes ripe at the end of March or early in April the Vines should not be started later than the early part of November, and they ought to be placed in position by the middle of October, so that they may have about a fortnight of preparation in the way of admitting air freely above 50°, this being secured by artificial means, and then the sap will become quickened, ready for starting the Vines away strongly when forcing proper commences. The canes must be depressed to a horizontal position, or lower, to secure them breaking regularly. Damp the canes morning and afternoon, but not keeping them constantly dripping with water. In an atmosphere kept at a temperature of 50° to 55° the buds will soon begin to swell, then gradually raise it day by day to 60° to 65° when they are breaking, allowing an advance of 10° to 15°

from sun heat. The temperature at the base of the pots ought not to exceed 75°, and it is better to commence with it at 65° about the pots, and increase the warmth as the growth advances. Water must be given very carefully at first, suffice that the soil be kept evenly moist, not in any case wet, as this retards rather than forwards root formation, and it is only when the Vines have leaves and evaporate largely that plentiful supplies of water are required.

Early Forced Houses.—Vines that are to furnish ripe Grapes with certainty next April should be started by the middle of November. It is not an advisable procedure to start Vines permanently planted at so early a season. Very early forcing places a great strain on them through their having to make growth when the natural conditions are at the worst for elaboration and assimilation, and to rest at the hottest part of the year, there being great danger of the foliage collapsing from attacks of red spider, or ripening too early from climatic conditions. This may cause the buds that are to furnish the next year's crop to start into growth at the time the Vines should be resting. It can only be avoided by retaining some lateral growths as an outlet for any sap which the roots absorb, and it will not do any harm, but good, by securing a considerable amount of stored matter, always provided the lateral growths are not allowed to interfere with the free access of light and air to the principal leaves. These laterals should be removed gradually and continually from late August until early September, so as to admit of the Vines intended for starting early in November or December by, or soon after, the middle of September, and they will not bleed, nor will the buds start into growth if the house be kept cool and dry. There is no need to wait until the leaves are all down, as the resting having set in there will not be any upward flow of sap ; but bear in mind this must have been secured by the gradual reduction of the laterals and the resting apparent, otherwise the pruning buds may start. If not already pruned lose no time in performing it, also the Vines to be started in December, not deferring pruning beyond the time the foliage commences to fall, so as to give the Vines a few weeks' rest.

Outside borders are a great mistake in early forcing Vines, especially Muscats, and whether heated below by hot-water pipes, or above by fermenting materials, not nearly equal to due internal provision for the roots. Still there are such borders, and have to be made the most of, or the Vines in them. The old practice of shielding them from the heavy autumnal rains by spare lights has not been improved upon, as it lets the border have the benefit of any sun that may appear, and that without depriving the soil of air. Thus later on the border can be covered with a good thickness of dry leaves or fern, with some litter on top, so placed as to throw off some of the wet, and the heat thus covered up remains most of the winter. Where there may be plenty of leaves and stable litter the well-tried practice of keeping out cold and getting some warmth into the border by placing them on top, renewing them from time to time, answers as well now as ever.

But we do not advise such procedure where better conditions obtain, yet adaptation to circumstances is a fine thing, and marks the cultivator as successful or otherwise. The very old practice of using fermenting material inside early forced vineries has not been bettered, as ridges of sweet fermenting material always give off heat, moisture, and nutrition, favouring good breaking and development of the growths, besides saving fuel. In the heap fashion ridges, like outdoor and indoor, for a very successful Grape-grower uses the stuff for growing Mushrooms and then spreads the beds over the border as a mulch for the Vines. Three parts of leaves, Oak or Beech, and one of stable litter, thrown into a heap a week or ten days before being placed in the house get warm, then placed in ridges on the border as shown in "Mushrooms for the Million ;" allowed to become hot, then turned a time or two, give out all the heat that starts the Vines, and the beds are spawned, earthed, and anon lots of Mushrooms appear, so there is a sweet air for the Vines after they start and the roots come into the sweet material.

The whole thing means abundance of nitrogen, for the old spawn decays along with the manure, prime stuff speedily passing into ammonia, and with occasional sprinklings of air-slaked lime soon gets into nitrate, and better, into the Vines. This may be a wrinkle for someone hard set to make ends meet. Anyway, we advise the ridges of fermenting material in early forced vineries, always using that rare article discriminative judgment where there are plants, sweetening the manure properly, or the foliage may be seriously injured by the vapour given off. Therefore mix well together when thrown into the heap, damping the materials if dry, turning when getting warm, again damping if necessary, and when well warmed through they are fit for placing in the house.

Midseason Houses.—Black Hamburghs, and other descriptions of thin-skinned black Grapes, have the colour taken out of them by hanging, and can only be lessened by keeping a good spread of foliage, or drawing a double thickness of herring-net over the roof lights. The latter is the preferable plan, as lateral growths interfere with light to the principal leaves, and the free access of air so desirable for maturing the wood. Those from which the Grapes have been cut may have the growths cut back to a few joints above the pruning buds, first curtailing the laterals and then cutting back the main growths. This insures the buds becoming plumper, whilst the freer access of light and air affects the wood favourably. A free circulation of air is necessary to expel damp, with a little constantly to prevent the deposition of moisture on the berries, a gentle warmth in the hot-water pipes being necessary when the external air is cold and damp ; but the wood being ripe and the growth matured it will suffice to maintain a temperature of 50°, and the cooler by day the house is kept the longer the Grapes will keep plump. Vines that have not the wood ripe should not have a less temperature than 60°, and this, with a free circulation of air, must be continued until there is no doubt on the point. Keep the laterals well in check, not allowing them to interfere with the chief growths. The border must not be allowed to become too dry, or the Grapes will shrivel, therefore afford a supply of water where necessary, always in the morning and on a fine day, so that air can be given and the superfluous moisture pass off. The watering will not do the least harm, for it is not moisture at the roots, unless excessive, that causes Grapes to spot and decay, but a confined stagnant atmosphere, moisture being condensed, it may be imperceptibly, on the berries that gives moulds their opportunity, which they never let pass by, but grow and multiply under the favouring circumstances. Keep well ventilated, and have no leaks in the roof, then all will be well with the Grapes.

Late Grapes.—Where the Vines were started in good time, say March, and aided in the spring by fire heat, as well as during the summer, the Grapes will be thoroughly ripe, in which state they can only be expected to keep satisfactorily, and the wood thoroughly matured ; all laterals or sprays may be removed down to the main buds, ventilating freely on all favourable occasions. Fire heat will only be necessary to prevent the temperature falling below 50°. Muscat of Alexandria, however, matures better in a temperature of 55°. To prevent dust falling on the berries, raking or sweeping must not be practised. Mats or clean straw laid over the inside borders will to some extent prevent evaporation. Outside borders need not be covered where the soil acts like a sieve, but where composed of somewhat moisture-holding material a covering against heavy rains is advantageous. Glass lights are best, wooden shutters good, and tarpaulin over dry bracken or straw answers well. A thick thatch of bracken or straw is very serviceable. Where the Grapes are not yet ripe the temperature must not be less than 70° to 75° by day and 65° at night, falling 5° through the night, allowing an advance to 80° or 85° from sun heat, continuing this until the Grapes are ripe, at least until the wood is brown and hard, for it is almost hopeless to expect good finish in Grapes that are not so by this time.

Young Vines.—The laterals must now be gradually cut back, letting the sun have a clear effect on the principal growths, not removing them all at once, but by degrees, getting them near the main rod with little further delay, so as to leave nothing but the chief cane or canes, and thus the principal leaves will plump the buds. Those having a tendency to continue growing to a late period may be checked by stopping the shoots moderately, facilitating the ripening by a high and dry temperature by day, starting of the heat and keeping the ventilators, except during frost, open at night. Afford water only at the roots to prevent the foliage becoming limp. This will harden the wood and tend to induce maturity of the growths.

THE FLOWER GARDEN.

Unsightly Flower Beds.—At this season of the year flower beds commence, from varying causes, to present a very untidy appearance, and the sooner the beds are put into a more orderly state the better in most cases. Where the beds have to be filled with shrubs and spring-flowering plants, as much as possible of this ought to be done before November. Dry weather should be chosen for this important work, as then it can be done without unduly disfiguring the walks and turf, and if the beds are a little on the dry side so much the better, nothing ever thriving so well when it is little better than puddled in. Therefore unhesitatingly break up the disfigured beds, and proceed at once with the work of refilling.

Hints upon Planting.—Nearly any kind or variety of Conifer in a small state looks well in masses, but the coloured forms of Retinosporas, Thuias, Cupressuses, Yews, and such like as specially prepared by the leading nurserymen for the flower garden, are by far the most effective. Variegated tree Box, Hollies in varieties, Berberises, Ivies, Osmanthuses, and Euonymuses are also admirably adapted for the decoration of flower beds, and with these may be associated Pernettyas, Cotoneasters, Skimmia japonica, and other berry-bearing plants. Very neat dwarf Rhododendrons in beautiful variety and well set with buds can also be had at a comparatively cheap rate, and these are very gorgeous late in the spring. Handsome trees 18 inches to 2 feet in height of the Conifers named are most effective when dotted among dwarf flowering and variegated foliage plants, and to these may well be added elegant Yuccas and variegated Iris. All transplant readily both now and again next spring, and if taken good care of are available for the beds several autumns in succession. Flowering plants, such as Wallflowers, Forget-me-nots, Silenes, Saponaria, Polyanthuses, Primroses, Daisies, Limnanthes, and others should, if provided in sufficient number, be planted rather thickly, as they seldom make much top growth, after being placed in the beds. See that they are in a moist state at the roots before they are lifted, move with a good ball of soil about the roots, and replant very firmly. Golden Pyrethrum, if not allowed to flower, will be available for replanting, and the smaller Beet from the flower borders or the kitchen garden will give a little colour for several weeks, and if the winter is mild look well till next summer, especially if the flower stems are pinched out. Old Violas should have straggling growths cut away, and if divided and replanted will present a very gay appearance next spring, flowering a little later than summer-rooted plants.

Spring-flowering Bulbs.—Freely used these enliven the flower garden surprisingly in the spring. Narcissi, Hyacinths, Tulips, Leucoiums, Crocuses, Scillas, and Snowdrops associate well with the shrubs and plants already named, or the beds may be principally filled with them and carpeted over with short neat pieces of tree Ivy, Box, Aucubas, Hollies, Laurels, Mahonias, and other evergreens, these presenting a fresh appearance, being a great improvement on the bare soil for several months, and

benefit rather than injure the bulbs underneath. Beds of Hyacinths in one colour edged with either Snowdrops, Crocuses, or Scillas in contrast are very gay, a change being afforded by a mixture of colours. The same remarks apply to Tulips and Narcissi, grouping them together answering better than general mixtures. In large beds circular patches of either Narcissi, Hyacinths, or Tulips might alternate with other flowering plants, or dwarf Conifers and shrubs, or they may be interspersed among the latter when these are thinly planted. If Hyacinths fill the centre of the bed dispose them 9 inches apart each way, while if the surface of the bed is carpeted with other plants, the bulbs may be put out 12 inches asunder with advantage, the crowns being covered about 4 inches deep. Where the soil is of a heavy nature surround each bulb with sharp sand; Narcissi to be treated similarly to Hyacinths. Plant the neat growing Tulips, notably the Van Thols, 4 inches apart and 3 inches deep, but the stronger varieties may be disposed 6 inches asunder. A little fresh gritty soil benefits Tulips, and the choicer varieties ought certainly to receive this extra attention. Snowdrops, Scillas, Crocuses, and Winter Aconite are most effective near the margins of beds, and planted in double lines or circles. Plant 4 inches deep, and not more than 3 inches apart. On light warm soils Ranunculuses may be planted in November, but where the soil is of a cold clayey nature keep them out of the ground till a favourable time arrives for planting in February.

Shrubby Calceolarias.—As yet these plants cannot well be dispensed with in the flower garden, and a good stock ought to be raised. It is not yet too late to insert cuttings. No bottom heat is required, but it is advisable to raise shallow frames well off the ground with the aid of old hotbed material not far advanced in decay; also partly fill the frame with the same and then cover with about 4 inches of light loamy soil, on this placing 2 inches of sifted soil, making this firm and level and facing over with sharp sand. Select short, firm, flowerless shoots; cut these below the third joint, and trim off the lower pair of leaves. Dibble them in at once and just clear of each other, taking care that the cuttings touch the bottom of the holes, fix firmly, and give a gentle watering. Keep the frame close and shaded from bright sunshine till the cuttings freshen up and fail to flag when the sun shines on them, after which ventilate freely in order to keep them as hardy as possible. Protect from severe frosts only.

Bedding Violas.—Autumn-rooted plants of these are by far the best for summer bedding, and properly treated they are unrivalled for brilliancy, especially during the early part of the season. Although much hardier (they are quite hardy in fact) Violas succeed admirably under precisely the same treatment as Calceolarias. Prepare frames as for the latter, and select the young shoots springing from the centre of the old plants; make these into short cuttings, dibble them in rather thickly, and treat exactly as advised in the case of Calceolarias. Failing plenty of the young central shoots make the best of the flowering tops into cuttings, as these will develop into very good plants, fresh growths springing up from below the surface next spring.

THE BEE-KEEPER.

The Season's Review.

At this season, when all is quiet in the apiary, and bee-keepers are comparing notes as to the result of the honey harvest, it may be of interest to state how the bees have fared from a honey producer's point of view in this district (South Yorkshire) when compared with those in the southern and more northern parts of the country. From an extensive correspondence with bee-keepers in many districts one is able to form a pretty correct opinion of what the harvest has been.

Bees throughout the country wintered badly. Never before, even in the most severe winters experienced during the past quarter of a century, were there so many losses chronicled, clearly showing that it was not owing to a low temperature. The winter was very mild; the lowest temperature registered was on January 24th—the thermometer on that date showed 14° of frost. The dull wet autumn of last year was the cause of bees wintering so badly, as during September 4·51 inches rain fell on twenty-five days. The following month 3·61 inches rain fell on twenty-three days.

It is during the autumn that the bees are bred that will live throughout the winter, and provide strong colonies the following spring. If from any cause the queen is prevented from carrying out her maternal duties the stock will suffer in a marked degree. From the above figures it will be seen that the bees were confined to their hives throughout the month of September. The result was at once seen. Breeding was at a standstill. The old bees, with which the hives were crowded, died off, as is usual at this season, in great numbers, and there were not sufficient young bees to take their place. The winter continued wet and mild, many colonies gradually dwindled, and were unable to recoup themselves.

The Weather and its Influences.

The above clearly shows the influence of the weather on bee-keeping, and the necessity of giving the bees assistance at the proper time. Although strong colonies may be well provided with stores to tide over the winter, it is a great advantage to supply each stock with a small quantity of thin syrup daily throughout September if the weather is dull and showery. This will have the effect of keeping the queen laying. I have no hesitation in recommending this plan, as several stocks in my apiary that were treated in this manner last autumn were far away my best colonies in the spring. This is a better plan than uncapping sealed stores in the autumn, although it answers remarkably well in the spring, when sealed stores are plentiful.

Unfavourable weather prevailed throughout the spring. A few fine days about the middle of May started the bees working in earnest. This was followed by dull, showery weather. June 12th and 13th were perfect days for honey production, being bright and warm, a shade thermometer on the latter date registering 86°. White Clover was fast coming into bloom, and as many stocks were strong and crowded with bees there was a great promise of a good honey harvest. Bee-keepers, however, were again doomed to disappointment, as dull weather again set in, and for three weeks the honey collected was only sufficient for the daily requirements of the bees.

The Swarming Mania.

The past season will be remembered by many bee-keepers on account of the swarming propensity of their bees and the number of fly-away swarms, the cause of which is not difficult to trace. During the honey flow, if the weather is warm and bright for a week or two in succession, the bees will settle down to work, and if ample space is provided for them to store a surplus little swarming will take place if due attention is given to shading and ventilation. But if after a day or two of excessively hot and bright weather, as experienced on the above dates, a spell of dull weather sets in, the bees will form queen cells and prepare for swarming, and when this takes place it is very difficult to prevent them doing so.

After three weeks of dull weather it again set in very hot on July 11th, and continued for several days. Bees were swarming in all directions. In an apiary of upwards of thirty stocks not a solitary swarm came off, but three colonies, not 100 yards away, managed on a different system, all swarmed. The queens were removed and the bees returned to their hives.

Late Crop of Honey.

The bright weather that prevailed throughout the country for at least a month from the above date was the means of a great amount of honey being stored. It was too late for the White Clover as the bulk of it was over, but the Limes were in full bloom, and the bees stored freely from this source. The season, however, was soon over, owing to the great heat, and instead of having to chronicle a failure, a really handsome surplus was stored in a very short space of time. In this district there has been quite half an average crop of honey harvested.

A bee-keeper in the West of England, writing early in July, says, "Our bees have done remarkably well; we have a grand crop of honey, and the best in every way we have had for years." Vegetation being earlier in that district, the bees were enabled to store a surplus during the fine weather that prevailed early in June.

In Northumberland and neighbouring counties there has been quite a "record" honey harvest, the White Clover being in full bloom when the bright weather came in July, and as the crops did not suffer as much from the drought in those districts, the bees were enabled to store a much larger surplus than those in the southern parts of the country, where vegetation was very much parched up; and it was only from the early flowers that bee-keepers in the south were able to obtain, in many instances, only a very scanty harvest. The honey generally has been of good quality. In this district it has been the best obtained for several years.—An English Bee-keeper.

TO CORRESPONDENTS

*** All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," **8, Rose Hill Road, Wandsworth, London, S.W.**, and **NOT** to Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Preserving Angelica (*W. Hubbard*). — The stalks of Archangelica officinalis are occasionally candied with sugar, and when so prepared are used in desserts by those who esteem them to "stimulate the stomach." The stalks have been also blanched and used in salads in the same way as Celery. We are unable to give you the details of preserving, but presume they are much the same as for Lettuce stalks and ginger. If any of our readers can supply the necessary particulars for preserving Angelica, we will readily publish them.

Paris Green as a Winter Dressing for Fruit Trees (*A. P. G.*).—It has been found, by many trials and carefully conducted experiments, that Paris green, applied to the stems and branches of fruit trees in October, has absolutely no effect on the eggs of the winter moth. There is nothing to equal the caustic soda and crude potash wash for cleansing branches of filthy incrustations when the trees are in a dormant state (see reply to "Pat"). We are glad you have found Paris green in other ways so beneficial to your trees. Thousands of winter moths have been caught by sticky bands applied towards the end of October or early in November.

Chemical Manure for Strawberries (*Henton*).—Nitrate of soda, 2 cwt.; dissolved bones, 5 cwt.; kainit, 10 cwt.. This very full dressing per acre should be applied as follows :—The kainit and phosphate in autumn, pointing in lightly; nitrate of soda sown broadcast in the following spring after the plants are well started, but before any bloom appears, having it crushed fine, and taking care to apply the nitrate when the leaves are quite dry. Ordinarily half the amounts quoted suffice per acre. We have used a mixture of bone superphosphate and kainit in equal parts in autumn at the rate of 5 cwt. per acre, and 2½ cwt. of nitrate of soda in the spring, with good results, especially on light land.

Destroying Weeds and Moss with Arsenical Preparation (*J. T.*).—Dissolve 1 lb. of powdered arsenic in 3 gallons of cold water, boil, and keep stirring; then add 7 gallons of cold water and 2 lbs. of crushed soda. Stir the whole well whilst boiling, and with a rose watering-pot apply to the walks in dry weather, from March to May inclusive being the best time. The above quantity will be enough for 25 square yards. An inclining board should be placed at the sides of the walks or grass to keep off the hot liquid. If you have Box edgings the soda and arsenical solution must be kept from them, otherwise they will be killed. Caution: Very poisonous. There are other methods of preparation, but why not obtain a ready-made weed killer?

Mushrooms in Pastures (*J. T. W.*).—The insertion of Mushroom spawn in pastures has been attended with good results in some cases, but without success in many others. Both the soil and weather must be favourable for the growth of the Mushroom plant within the soil. The best practice is to prepare some manure as described in "Mushrooms for the Million;" and from the middle of May to the middle of June, just as dry weather prevails, or a prospect of it is likely, take out squares of turf about 3 inches deep and the size of a spade, removing sufficient soil to admit of a large forkful of the manure, and in the centre of this place about a quarter of a brick of spawn, replacing the turf at once and treading and beating it down to make hard and level as before removal. Elevated parts of the ground are better than damp hollows. Crushing and sowing spawn over a field to the extent of a bushel or so provides the requisite legal conditions for prosecuting, as any Mushrooms that appear are then regarded as "cultivated," though the process itself does not bring them. A dressing of salt 5 cwt. per acre in February has been followed by abundance of Mushrooms, and also benefits pastures, especially in dry districts. "Mushrooms for the Million" can be obtained by post from the publisher, 171, Fleet Street, London, in return for 1s. 2d. in stamps.

Large Beans (*No Name*).—It is contrary to the rules of the *Journal of Horticulture* to insert communications from correspondents who withhold their names and addresses from the Editor, though the names of writers are never published against their wishes. It is not, of course, necessary for regular contributors to sign their names on each MS., as they are perfectly well known.

Freaks of Fungi (*J. Smith*).—The small Mushroom-like specimen you send is exactly the shape of those familiar round bread loaves with a small "naggin" on the top. You may call it, if you like, a Mushroom two storeys high. When the small tubercular growths form in a dense mass some of them get displaced by the pressure, and occasionally become piled one on the other, those elevated, if resting closely, being supported through the tissues of others below.

Artificial Manure for Black Currants (*H. T.*).—Sulphate of ammonia, ½ cwt.; dried blood, ¼ cwt.; fish meal, ¼ cwt.; dissolved raw bones, dry and crumbling, 2 cwt.; muriate of potash, 1 cwt.; these = 4 cwt. Apply now, or after the late autumn or early winter pruning, forking-in lightly. For use as soon as the buds commence swelling in the spring - nitrate of soda, ½ cwt., and mineral superphosphate, 37 per cent. soluble phosphate of lime, ½ cwt., distributing evenly when the ground is moist. The dressing is for 1 acre. The dressing is a full one, half sufficing if only moderate growth is wanted.

Keeping Catillac Pears (*A. G. G.*).—A sweet cold cellar inclining to be damp would be better for the fruits than a very dry room. We have more than once found fruits of this Pear that have passed the winter among the grass of an orchard as sound in the spring as when they fell from the trees six months previously. This is mentioned as proving the hardiness of the "Iron" Pear. We have known the fruits to shrivel in very dry rooms. If you keep yours firm they will realise more money in the spring than at the present time. There is not infrequently a good demand for them in March and April.

Apple for Forming a Screen (*R. W.*).—A gardener who has practised at an altitude of nearly 700 feet above sea level says:—The closest growing, hardiest Apple for forming a screen to the north was Hunthouse, a rather small tree, with somewhat pendulous growths, of immense productiveness. The trees were 3 feet apart, cut hard back, and grown exactly like a Thorn hedge, only the knife was used instead of a bill or shears. Inside this was another hedge of Carlisle Codlin, 7 feet 6 inches from it, a free-growing variety when young, but bearing early, soon getting hedge like, and that gave fruit in abundance from August to December. The outer hedge was kept 4 feet, and the inner 6 feet high. In another place, but in one hedge, he had Manx Codlin, fruit in season August till November; Minchull Crab, November to March; and Northern Greening or "Robin," November to April, the object being to get a long succession of useful culinary fruit; but the trees did not succeed well so mixed, as the Northern Greening outgrew the others. As the result of his experience he recommends - for a low screen, Manx Codlin on English Paradise; tree very hardy, remarkably healthy, early and abundant bearer. For a medium-sized screen.—Minchull Crab, also on English Paradise; tree very hardy, not subject to canker or plagues of insects, and an abundant bearer. For a large screen.—Northern Greening on English Paradise; tree very hardy, strong grower, and abundant bearer. Distance, 2, 3, and 4 feet respectively. Perhaps some of our correspondents can improve upon the three varieties, but the condition is they must be of undoubted hardiness.

Growths on Vines (*Pat*).—The small warts, or excrescences, are caused by the piercing of the tissues of the Vine at the junction between spur and rod, where there are probably aërial roots, by the beaks of the Grape Vine louse (Phylloxera vastatrix). There are present in the rough parts the hibernating form, a most remarkable thing, and probably a consequence of the whole border being "sour and bad," so much so with wetness that the insect chose to hibernate on the rods rather than on roots, as usual. Of course, there are other things belonging to this most disastrous insect pest of the Grape Vine, and we are going to tell of a very simple mode of killing it. 1, Remove the warts, or excrescences, such as those you sent us, and burn them; prune early, and then dress every part of the Vines above ground with the following solution—Caustic soda, 98 per cent. purity, 2 ozs.; crude commercial potash (carbonate of potash, or pearlash), 2 ozs.; water, 1¼ gallon. Dissolve each separately in a pint of water, add together, then the remainder of the water boiling. Apply with a clean half-worn paint brush, reaching well into every angle, hole, and crevice, the solution being at a temperature of 130° to 140°, and not used excessively, but taking care to wet every part of the rods and spurs. Loose bark may be removed, but do not peel the rods or spurs into the quick or live bark. Carefully collect and burn all the prunings and peelings. Having attended to the rods, rake off any loose surface material, not injuring the roots, and char it on the rubbish heap. Then water the border with a solution of Little's soluble phenyle, 1 part to 96 parts of rain or soft water—that is, a quarter of a pint to 3 gallons of water, and apply with a rose watering can, giving the amount quoted, or 3 gallons per square yard of the solution duly stirred, then a milk-like preparation. The soil must be moderately moist, so that the solution will enter and moisten the whole evenly, without having to give an extra dose to effect it. It will not matter if the soil be already wet, for the solution will force the excess water out or take its place. The pest chiefly acts on the young roots near the surface, and especially near the stems or collars, therefore apply from these outwards, but to every part of the border. The solution of soluble phenyle may be used again just before the Vines start into growth. It acts as a manure, which will show itself in the Vines next year. Caution: No other form of phenyle or phenol may be used, it being absolutely imperative that this be soluble.

Saccolabium bellinum (*Young Orchidist*).—You will find on page 309 an illustration with a note, which will probably give you all the information you require. If it is not so, write again.

Name of Caterpillar (*Semper Fidelis*).—The specimens sent are those of the Privet hawk moth (Sphinx Ligustri), a species generally distributed over England, but more abundant in some districts than others. It feeds chiefly upon the shrub from which its name is taken, but is also found upon Lilac, occasionally upon Apple. It has been said to eat Laurustinus, but this is rather doubtful. Some seasons the caterpillars are numerous enough to leave signs of their residence on the Privet hedges. While young they are apt to escape notice, being much the colour of the foliage. When nearly full grown they usually mount the upper twigs at night or early morning, and in the day retire to the interior of the bushes, probably to escape hungry birds, to which such a fat caterpillar might be a tempting morsel. During September they descend some depth into the ground, and form a chamber, where the chrysalis reposes till the months of June or July.

Rose of Sharon and Star of Bethlehem (*John Thomas*).—You ask "under what name the Rose of Sharon goes in Johnson's Gardeners' Dictionary." It goes under no name so far as we can see in the last edition of that work. Neither is it included in the list of popular names in Sanders' Encyclopædia; but in this work it is found in parenthesis after "Hypericum." In many districts the name is commonly applied to Hypericum calycinum—a low, half-shrubby evergreen. But this cannot be the plant you have in view, as you say the "bulbs have come from Jerusalem." There has thus possibly been a mistake in writing down the popular name "Rose of Sharon" instead of "Star of Bethlehem." This is given in the Dictionary under its popular heading, with a reference to Ornithogalum umbellatum, a British species. Sanders does not include Star of Bethlehem in his popular name list, but we find it in his work under Ornithogalum, with a reference to O. longibracteatum, the familiar "Onion plant" of cottage windows, and a native of the Cape of Good Hope. The fanciful name Star of Bethlehem seems to have become attached to the Ornithogalums as a genus, but it would seem to be more strictly applicable to O. armeniacum than to the species above named, as this is a native of the country in which both Jerusalem and Bethlehem are situated—Armenia. Your bulbs may therefore be those of the Armenian species. It is hardy, as also is O. umbellatum, but O. longibracteatum is not.

Names of Fruits.—*Notice.*—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. *In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing.* The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. *They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state.* (*W. J.*).—A fine specimen of Hollandbury. (*A. T. S.*)—1, Beauty of Kent; 2, Warner's King; 3, Annie Elizabeth; 4, Tower of Glamis; 5, Potts' Seedling; 6, Beurré Diel. (*I. G.*).—1, Bismarck; 2, Sandringham; 3, Egremont Russet. (*H. R. M.*).—1, Blenheim Pippin; 2, Annie Elizabeth; 3, Lord Derby; 4, King of the Pippins.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*R. B.*).—1, Rudbeckia nitida; 2, Helianthus rigidus Miss Mellish; 3, Anemone japonica alba. (*F. F.*).—1, Helenium autumnale; 2, dead; 3, Adiantum pubescens; 4, Asplenium bulbiferum. (*C. H., York*).—According to your letter the specimens were packed on the 23rd inst., and then misdirected, and had to be reposted, not arriving at their destination till the 28th, a Sunday intervening, with its no postal delivery in London; the natural consequence of such delay was the drying of the samples beyond all possibility of identification.

GARDENERS' CHARITABLE AND PROVIDENT INSTITUTIONS.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—*Secretary*, Mr. G. J. Ingram, 50, Parliament Street, London, W.C.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—*Secretary*, Mr. W. Collins, 9, Martindale Road, Balham, London, S.W.

SWINE FEVER.

WHEN Richard of the Lion Heart ruled, or rather allowed others to misrule in his name, in this pleasant England of ours were vast tracts of unreclaimed forest land, beautiful in its diversity, and affording in its sylvan retreats shelter and food for animals of the chase, as well as those peculiarly adapted for the domestic spit.

What our forefathers would have done without the homely swine we know not. How we ourselves should feel were the pig removed at once and for ever from our list of food supplies, we know very well. In this climate, where we have far more cold days than warm ones, we need a large amount of fatty matter to help keep up our vitality. We have pig served in a hundred ways, and on every table, save those purely Jewish. The fat is not so repugnant to the delicate stomach as the fat of other animals. It is easily cooked, and makes a tasty relish, and above all, on the list of animal food, we find in it so much greater proportion of meat to the bone. This makes it intrinsically cheaper. It can be bought in small quantities at the tiny village shops,

and, well cured, it is not liable to deterioration arising from sudden changes in the weather. Hence arises its popularity, a popularity which it will take a revolution to check.

If we could have wandered in the forests of Rotherwood side by side with Gurth and Wamba, we should have been amazed at the appearance of their porcine charges. The pig now is so truly an animal of the homestead, that we should hardly have identified their long, lean, hungry, wild looking, half savage drove with our sleek, indolent, Barley-fed friends, and yet we doubt not what they lost in flesh, and form, and pedigree, was made up to them by a greater delicacy of flavour. There would be a gaminess about their bacon that we miss. Fancy the nuttiness imparted by an unrestricted diet of acorns, beech masts, and the thousand and one dainties of the woodland banquet. We get weight with our meal and Potatoes, our fore-elders got flavour; just as at the present time there is such an infinite difference between the Indian corned pheasant and his really wild brother. A veritable novice can tell the difference at the first mouthful.

Up to late ears pigs were fairly exempt from all ills save concussion of the brain and sore throat; now we never take up a paper without a record of closed pig markets and a fresh outbreak of disease in some part of the country or another. Swine fever is the name given to this tiresome disease, and it appears that although compulsory slaughter is insisted upon when any case is reported to the authorities, the disease is by no means vanquished, but barely kept in check. Like rinderpest or cattle plague, swine fever is in England a comparatively new disease.

It appears that in the year 1862 there was in Berkshire an outbreak of disease of a most virulent nature, which was specially investigated by Professor Symonds. Unhappily no measures were taken to prevent the spread of this disease till 1878, when the public began to wake up to the fact that something must be done of a preventive nature. In December of that year an order was passed providing for slaughter of diseased swine by the local authority, and also this authority had the power to slaughter swine which had been in contact with the disease. There were also certain regulations respecting the moving of swine from suspected places except by licence.

For four years these measures were carried out, but with little success—*i.e.*, the disease was not really checked. In 1892 there was a certain reduction in the number of cases reported, but the reduction arose from two facts: Firstly, that there were fewer pigs in the country; secondly, because as the local authorities made no compensation to the owners of animals slaughtered, there was an unwillingness on the part of those owners to report doubtful cases.

It seems almost an impossibility that this disease should wear itself out, as some diseases will do. It is of the most virulent nature, both infectious and contagious, and the infection can be imparted from herd to herd in the most unsuspected manner. Things being in this state, the Board of Agriculture appointed a committee to inquire into certain matters relating to swine fever; this was in February, 1893. The committee all agreed as to the very serious nature of the disease, and were unanimous in their recommendation that the work of exterminating the disease should be placed in the hands of a central authority. This central authority should be empowered to slaughter, and pay the cost of the execution of the Act and orders. Slaughter of diseased animals and restriction of "suspects," with thorough and proper cleansing and disinfecting of sties or yards, were absolutely necessary.

Usually the disease is acute and rapid in its action, and again there are cases which are more or less chronic, and would be unnoticed by the casual observer. A pig may appear to be what is called "unthrifty," and yet when a post-mortem examination takes place there may be most convincing evidence of the presence of this disease.

The Board of Agriculture have issued their report for 1896 on the "Diseases of Animals," and we find from that report that swine fever still continues to be the most obstinate of all the zymotics.

This disease continues to break out in the most unsuspected places, and where the source of infection baffles all investigation. Last year the Department examined 23,137 suspected cases, and found 5166 outbreaks. Swine owners appear to be very much on the alert, and by reporting at once any doubtful cases give the inspectors every chance. The report says, "The great factors in perpetuating swine fever will always be pigs which are affected with that disease in the less fatal and unrecognisable form. These animals are constantly distributing the germs of swine fever through their highly infectious evacuations, wherever they may be taken during the whole period of their illness, and the final extinction of the malady must depend upon the possibility of enforcing measures which will have the effect of preventing the movement of pigs affected with swine fever in this particular form."

A word in conclusion. Our losses from actual death and the closing of markets have been enormous. No farmer knowingly keeps a doubtful cow or bullock on the premises an hour longer than he can help. Why not extend the same rule to pigs? We fear it is not the farmer who in this case is to blame, but those hundreds of small pig owners who will doctor and drug ailing pigs as long as there is breath in their bodies, and who are not very careful as to the disposal of those bodies when merciful death at last supervenes.

WORK ON THE HOME FARM.

We have made good headway with autumn cultivation since our last, and a couple more days will see the last of the twitch fired. We shall not plough the land at present, as a few bits near the surface may grow, and another harrowing in October would make a clean sweep of them.

Lea is about all ploughed, and is being rolled with the ring roller. This must not be neglected if a good plant of Wheat is to be secured. A low-lying piece of land, too strong for ordinary autumn dressings and rather foul, is now being ploughed deep and wide with the chilled plough for the purpose of leaving it as rough and open as possible. It will be left thus through the winter, and we hope it will get a thorough freezing.

Not much Wheat is grown now on summer fallow; but where it is to be so grown the sooner it is sown the better. Mid-October is early enough after lea, and on lighter soils a week or two later would be advisable. There is a fashion for winter Oats and Barley, and we often see the seed of such advertised. Winter Oats come to maturity early, and often command a good price. Winter Barley we do not care for.

We still stick to Square Head and Square Head's Master as being the most profitable kinds of Wheat to sow, but for lighter soils we should prefer Royal Stanhope or White Queen. We have heard an excellent character given of the latter by a large Wheat grower.

There has been a good deal of Wheat smut, or, more properly speaking, "bunt" about; this is most likely due to the neglect of dressing the seed before drilling. There are many mixtures recommended for the purpose, every local chemist having one of his own, but as the valuable constituent in them all is blue vitriol, we prefer to buy it in the vitriol form. One pound of finely powdered blue vitriol will be sufficient to dress a quarter of seed. It must be well dissolved in water before application, and after the Wheat must be well turned so as to insure the damping of every grain with the solution.

REMARKS.

19th.—Sunny morning; overcast from 2 P.M.; rain in evening.
20th.—Dull early; bright sun from 10 A.M.
21st.—Rain early; bright sunshine from 9.30 A.M. to 3 P.M.; cloudy after.
22nd.—Fair, but almost sunless.
23rd.—Bright sun all morning; frequently cloudy in afternoon and evening.
24th.—Overcast, with high wind in morning; frequently sunny in afternoon.
25th.—Bright sun from sunrise, but hazy from 10 A.M.; cloudy from noon with frequent drizzle; solar halo at 0.30 P.M.

A dry week, temperature near the average.—G. J. SYMONS.

Journal of Horticulture.

THURSDAY, OCTOBER 7, 1897.

THE JOURNAL OF HORTICULTURE *can be obtained from the Office,* 171, *Fleet St., London, post free for a Quarter,* 3/9. **Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.**

PROGRESS IN FRUIT AND VEGETABLES.

CONSIDERING the nature of the season, and the sparsity of fruit in many districts, the Fruit Show held at the Crystal Palace last week, under the auspices of the Royal Horticultural Society, must have fully equalled, if not excelled, all reasonable anticipations. Though not appearing on the "face of it" so large as the show of last year, it was really larger, upwards of 6000 dishes being staged. The method of arrangement was different, this being governed by the site at disposal, and though the effect may not have been so imposing at a glance as that presented at previous exhibitions, the magnitude of the display seemed to grow on the minds of visitors as the several exhibits were re-inspected, and practically the method of arrangement was more convenient than that resorted to on previous occasions.

With these preliminary remarks, and the registering of a well-deserved compliment to Mr. S. T. Wright of Chiswick, and Mr. G. Caselton, the Garden Superintendent of the Crystal Palace, for their successful exertions in the disposal of the produce, for the convenience of Judges and visitors, we leave the show itself, or rather delegate a description of it to a subsequent page, and pass to a feature in connection with the event that is worthy of prominent attention.

Having in view a great historic fact, which only needs an allusion for its being understood, it will be conceded that the word "sixty" represents the golden number of the present year. There are "sixty" medallists who will receive their decorations one of these days, the exact date of which, if all we hear is correct, is due to an accident, for which the Royal Horticultural Society is not responsible; and then, as was natural under the circumstances, a narrative of "Progress in Horticulture" suggested a theme on which experts might expatiate for the general edification. A "conference" was thus arranged, to extend over the three days of the show—namely, on "Progress in Fruit Culture" during Queen Victoria's sixty years' reign, opened by Mr. G. Bunyard, F.R.H.S.; in "Vegetable Cultivation," by Mr. A. W. Sutton, F.L.S.; and in "Market Garden Cultivation," by

Mr. J. Assbee, F.R.H.S.; and all who had the privilege of attending the meetings will be satisfied that no gentlemen more competent could be found to deal with these important subjects.

Only an outline of the general character of the addresses delivered will be given here. They will presumably be found *in extenso* in a forthcoming issue of the Journal of the Royal Horticultural Society that will be distributed amongst the Fellows; and here let it be said that the contents of the periodical issues of the Society's official organ seem to become more and more interesting, and at least equal in value the amounts of the subscriptions of the great majority of the Fellows to the Society.

Taking the subjects in the order above mentioned, Mr. Bunyard, in his "Progress in Fruit Culture," first gave an outline of the character of a well-kept garden in 1837, mentioning the varieties of fruits that were then generally grown against walls and on borders of diverse aspects. He brought under review Apples, Pears, Plums, Cherries, Apricots, Strawberries, and other kinds which were then the most popular. He pointed out the extreme care of the gardeners of old in the management of wall trees, and feared that such care was rarely exercised now, the modern gardener depending more on under glass produce.

The essayist went on to recognise the work of the old masters in advancing the art of fruit culture, such as Messrs. Ronalds, Thompson, Wilmot, Pearson, and especially Mr. Thomas Rivers—the "father of garden or bush tree culture"—who did such good work in improving the quality of British fruit. Nor were what may be termed legislative and mechanical matters overlooked, such as the abolition of the glass duty in 1845 and the introduction of heating by hot water, with the invention of the tubular boiler by Mr. E. Weeks in 1835, and its subsequent improvement.

Mr. Bunyard also naturally adverted to the exhibitions and conferences of the past as giving great stimulus to fruit culture, especially the Apple Congress at Chiswick in 1883, and the memorable show in the London Guildhall in 1890. There is little doubt that those two events gave a greater impetus to fruit growing in Britain than any other efforts during our good Queen's reign. He did not tell us that the Guildhall Show would not have been forthcoming but for the spirited undertaking, during a "bad fruit year," of Mr. A. H. Smee and himself undertaking to fill the Guildhall if no one else would join in the endeavour, but the fact was brought out in the subsequent discussion.

Brought under review also was the literature pertaining to fruit, prominent place being given to the late Dr. Hogg for his classic work, the "Fruit Manual." The works also of Messrs. Rivers, Bull, Wright, Cheal, and others being cited, as each in its way (as the speaker's own works have done) helped forward the object in view. Amongst workers in the cause of fruit culture the late Sir Henry Scudamore Stanhope of Holme Lacy was justly referred to as a leader, followed by such practicalists as Messrs. Ingram, Jones, Woodbridge, Ross, Speed, Thomas, Woodward, Wildsmith, Ford, McIndoe, Hunter, Goodacre, Luckhurst, and others; while even the gardening press was not overlooked.

As will be perceived, the address was comprehensive, but while the author fully admitted the good work of the past, he looked for, and confidently anticipated, still better work in the future from the skilled and intelligent gardeners of Britain; and so does the *Journal of Horticulture*.

Mr. A. W. Sutton followed the next day (Friday), and in a comprehensive paper dealt with the progress of vegetable cultivation during the Queen's reign. This has, at least, been as marked as in the case of fruits, and with results certainly not less important. It transpired that the grand old octogenarian and founder of the great Reading firm was asked to contribute a paper, but as his physical powers were not equal to his mental activity it was prudent for his son to act in his stead.

Mr. Sutton observed at the commencement that, though the "cultivation" of vegetables was mentioned in the programme, he thought it would not be expected of him to enlarge on that aspect of the question, but rather to speak on the improvement of the vegetables cultivated. This he did for nearly an hour without a tedious moment to his hearers. He commenced with what he called the "Prince of Vegetables"—the garden Pea, mentioning the principal varieties that were grown in the thirties, including the Scimetar and Charltons, tracing improvements step by step to the present day, which have culminated in a revolution.

Mr. Sutton observed that real interest was awakened in the improvement of Peas by the introduction of the famous Ne Plus Ultra, which came out as new under several names during three or four consecutive years—no small tribute to the intrinsic merits of the still favourite of many cultivators. Passing along, the speaker noted a distinct gain effected by the introduction of Veitch's Perfection, Dr. McLean's seedlings brought out by Mr. Charles Turner, and Mr. Laxton's varieties. A special tribute was paid to the work of Mr. Culverwell; and the varieties Telegraph, Telephone, Stratagem, Pride of the Market, and others introduced by Messrs. Carter, were cited as examples of further progress. Sharpe's Queen, Webb's Wonder, and some of Mr. Eckford's varieties, all had recognition, Duke of Albany having a special mark of approval. It was obtained by selection from Telegraph by Mr. Abbott in Mr. Firth's garden at Sheffield.

Nor could the essayist omit mention of the early large-podded Marrowfats on dwarf sturdy stems, plants of which went direct from the Temple Show last year to the entrance hall of Windsor Castle, the varieties having subsequently become favourites at the Royal table. Such varieties as Daisy, Veitch's Maincrop, Alderman, and Laxton's Gradus were also cited as good additions to modern Peas.

Interesting were the remarks on raising and fixing the characters of Peas. As the result of cross fertilisation every pea in a pod may produce a different variety, and these again show variations, so that watchful care and prolonged patience were needed in firmly establishing new varieties. Sending new Peas out too soon results in confusion. The preservation of purity in stocks also, as all seedsmen knew, entailed more labour in sorting and selection than the outside public had any idea of.

Adverting to Broad Beans, Mr. Sutton regarded them as more stationary than most vegetables, but was still surprised the old Mazagan should be so much grown, since there were both earlier and better varieties. For usefulness an approving word was given to the Harlington Windsors. Then there were the continental Longpods, such as the Seville, but the English Giants were hardier and better. We do not know to what particular section Bunyard's Exhibition belongs, nor was it mentioned, but we have seen it win many prizes in large competitions at cottagers' shows. Of French Beans, varieties were mentioned, including Fulmer's Forcing and Negro, that were grown in 1837. Among the greatest advances since were Canadian Wonder and Ne Plus Ultra, though there were newer sorts which have come to stay. A few words of warm approbation were given to the new climbing French Beans, both for their productiveness and tenderness, while the old Scarlet Runner has given rise to forms remarkable for the length of their pods.

Passing reference was made to Asparagus, preference being given to the best selections of Argenteuil for cultivation, while there was room for improvement in the cooking of this delicious esculent.

Ancient varieties of Beet were mentioned, also modern improvements, such as Nutting's, Dell's and Cheltenham Green Crop; while the old flat Egyptian Turnip-rooted was being superseded by the symmetrical globe-shaped forms. Similar improvement was apparent at exhibitions in Carrots, while perfect models were also to be had in Turnips, thanks largely to the selections of Messrs. Dobbie. As to Parsnips, the chief advances were found in Student and Carter's Maltese, but a new variety named Tender and True has recently been exhibited, which is said to exceed all others in quality.

The Brassicas received a goodly share of attention, beginning with the Cabbage. A hint was given that the very early continental varieties, such as Express and others, were like the old Early York, only suitable for spring sowing, for which also the Nonpareil is valuable.

If sown in the autumn the plants "bolt," but not so Ellams' Early, Imperial, Flower of Spring, and Early April, which when true form solid hearts. Brussels Sprouts had mention, and the sportiveness of the Brassica family suggested the possibility of a Brussels Sprout with red buttons, and this brought out the observation by Mr. Bunyard that Red Cabbages were delicious when well cooked. The greatest addition to Cauliflowers during recent years was Veitch's Autumn Giant, while most valuable were the Early Erfurt varieties, as represented by Snowball and First Crop; and as for Broccoli, these were to be had now as clear as the Cauliflower, and white heads of one or the other could be had all the year round.

For improvement in Onions credit was given to the late Mr. Deverill, and for Leeks to Messrs. Dobbie, but in respect to the latter it was remarked that though the gigantic samples were indispensable for exhibition, much smaller stems were far superior to them for table use. Lettuces have been increased enormously in both the Cos and Cabbage sections, and there was now an excellent one partaking of the nature of both. Relative to the trouble of boltiug, the speaker observed that there were now Cabbage varieties such as Favourite and Daniel's Continuity that often refused to produce flower stems at all.

From the White and Black Spine Cucumbers of sixty years ago we had now a host of superior varieties. Rochford's was much sought for, Telegraph highly serviceable, but Mr. Mortimer had raised varieties with the most perfect fruits, such as Progress, Matchless, and others that had been honoured by the Royal Horticultural Society.

As evidence of the striking advance in Tomatoes, Mr. Sutton observed that only one, the Common Red, was to be found in a wholesale seed list in 1852, whereas the trials at Reading now included 200 selections. Some of the best were mentioned, including Mr. Thomas' Frogmore Selected and Golden Jubilee, which had such an imposing effect in the Show. In the course of discussion it was generally acknowledged that though large fruits were in favour for showing, those weighing six or eight to the pound were preferred by general consumers, and Mr. Bunyard remarked that in his view the true Chiswick Conference was one of the most useful.

A reference to Potatoes was left to the last. In 1836 the speaker said 166 varieties were listed by Messrs. Peter Lawson & Sons, and though a few remained, including the Shaws and Dons, only one was generally cultivated—the Early Ashleaf. Others had fallen a prey to disease through constitutional enfeeblement. Mr. Sutton believed that some of the early American varieties, such as Beauty of Hebron and Puritan, had been of great service, and with those and home-raised late varieties the present Potato supply, once in dire jeopardy, had never been equalled. Among those who had brought this about by raising new varieties, appreciative reference was made to Mr. Robert Fenn, Mr. A. Findlay, also to the late Messrs. James Clark and James Paterson.

Broadly speaking, Mr. Sutton thought that greater advance had been made in vegetable cultivation during the last sixty years than in the two centuries preceding the Queen's accession to the throne. Mr. A. Dean, in a few pertinent observations, thought some credit was due to cultivators as well as to raisers, and the meeting appeared to think so too. Mr. Sutton's admirable paper should be read in full by all who are interested in the important subject which he so ably treated.

Saturday brought to the front a different subject, and one in which progress has advanced by leaps and bounds, especially during the later year of the Queen's reign—namely, market gardening. This is a subject, moreover, on which only a comparatively few persons can treat authoritatively and comprehensively. Mr. J. Assbee is well able to do so for two of the best of reasons. First as superintendent of the greatest garden produce market in the world—Covent Garden—he has abundance of materials at command; and secondly, literary ability of that particular kind which enables him to impart to others with great clearness that which he wishes them to understand.

Mr. Assbee commenced by saying that the annual gathering of the Royal Horticultural Society in the famous Gardeners' Palace seemed to afford a suitable opportunity for reviewing gardeners' work. In the production of food from the soil he presumed that every man at the outset was his own gardener, and supplied his own wants as well as he was able. As communities formed and small towns became established many of the inhabitants would purchase what was needed from contiguous land or local market gardens, as was in fact the case now.

As the aggregation of people became greater, resulting in populous towns and cities, shops would become necessary, and these would have to be regularly supplied with large consignments of produce of different kinds in season. Thus market gardens would be formed on a scale commensurate with the demands, and systematic methods of culture acquired and pursued. These gardens would first be situated in the vicinity of towns, as many still are, while many have been driven farther afield by builders.

The development of railways gave wider scope to cultivators, and enabled them to choose distant fields for their operations, while improved methods of production would be adopted. Thus did market gardens grow with the growth and wants of increasing populations, until they have covered their present enormous area. Market gardening has now become an art. It is not a mere speculative undertaking by those who successfully engage in it, but is conducted on sound business principles and carefully considered lines of procedure.

Striking figures were adduced as to the extent of the cultivation of different products. For instance, if we understood rightly, 4000 acres were devoted to the cultivation of Asparagus in Middlesex, which, though the largest is only one source of supply, the yield being 1,600,000 bunches, though much larger supplies came from the Continent. Celery is grown by hundreds of acres in Lincolnshire, and Onions in Bedfordshire; but still as the importations of Onions amount to about 6,000,000 bushels, valued at nearly £700,000, the markets do not seem to be overburdened with the home supply.

The forcing of vegetables was alluded to, mention being made of the enormous output of Leeds Rhubarb, which is brought to London to the extent of 30 tons a day in the season, and enormous supplies are grown in the metropolitan district. The hardy fruit demand and supply have increased marvellously, and not less remarkable is the extension in the culture of forced fruits in the neighbourhood of London, Worthing, and in other centres.

The cultivation of flowers for market has attained to stupendous dimensions. From Snowdrops, through the whole floral range, the public wants have to be met, and both home gardens and foreign fields are placed under tribute to maintain the supply. A wonderful instance was given of progress in Daffodils in the Scilly Isles. Mr. A. Dorrien Smith of Tresco commenced their culture by sending £1 worth to Covent Garden in 1865. This small beginning culminated in a supply of 496 tons during the present year.

In the production of flowers and plants for market many thousands of persons are employed, and the extent of glass devoted to the work and to the forcing of fruits and vegetables in England is computed at 32,000,000 square feet, or equal to a range of 15 feet wide houses 400 miles long. So we seem to be doing a little of something in England after all. Under glass culture is extending, but Mr. Assbee seems to think there is a danger of those amateurs who enter on this work, because they think it a pleasant occupation and profitable investment, not realising anything approaching their anticipations, as in the absence of great business capacity and thorough knowledge of the various details of the work, trouble and loss are more likely to follow than pleasure and profit.

We have given the merest outline of Mr. Assbee's excellent paper, as well as the others, and they must be read in their entirety in the official *Journal*, in which they will in due time appear.

It should be stated that the extremely active King of Siam, after a visit to Southampton on Friday, arrived at the Crystal Palace at 6 P.M., with his retinue, to see the show. He flitted from stand to stand, making no secret of his delight; this perhaps culminated with Mr. Rivers' fruit trees in pots, and after satisfying himself that the fruits were not tied on, observed there was nothing like them in his country. His Majesty, after seeing much in a little time, dined at the Palace, and was presented with a magnificent Pine from the exhibit of the Queen.

TWO NOTABLE KENTISH FRUIT MEN.

We give two portraits in the present issue (figs. 50 and 51) of men who over a series of years have exhibited hardy fruit as well, we doubt not, as it has ever been exhibited at home or abroad. True, they may have soil and climate, which conduce to both the size and the colour of hardy fruit; but neither Mr. George Bunyard the nurseryman, nor Mr. George Woodward the gardener, could have accomplished what they have in the absence of skill in cultivation. As a matter of fact we have seen fruit as small, scrubby, specked, and inferior in Kent as in any other county; and that which is so good is made so by making the best of such natural advantages as exist in climate and in soil. Both these growers and exhibitors have done yeoman's work in hardy fruit cultivation. To enumerate the honours they have won would fill a page, and we shrink from the task of compilation. Maidstone is at present in an unfortunate position, but the fruit-growing area of both our friends is some two to four miles from the town, and though they deeply regret the calamity that has befallen it, they happily feel as safe as if they were a hundred miles away. We congratulate both Mr. Bunyard and Mr. Woodward on what they have done in the past, and trust that health and strength will be vouchsafed to them for not less signal successes in the future.

Fig. 50.– Mr. George Bunyard.

CRYSTAL PALACE FRUIT SHOW.

September 30th, October 1st and 2nd.

Once again the Royal Horticultural Society has to be congratulated upon a very successful exhibition of fruit. Opinions had been very freely expressed as to the probable poorness of the show owing to the adverse weather causing a light crop. Notwithstanding this, the show was a very fine one indeed, and we learnt that 1000 more dishes were staged than was the case last year. This would not strike one as being the case, as the exhibits were arranged in a different manner and place from what has hitherto been the custom. As is well known, on previous occasions the tables have occupied both ends of the centre transept, and thus made an effective and imposing display. This year, with the exception of a few nurserymen's stands in the transept, the majority of the tables were in the central square before the large organ. If the show lost somewhat in effectiveness by this system, the public were the gainers in being able to find the classes much quicker and easier than in former shows.

It is superfluous for us to say that the Apples were the best feature of the whole show. If the fruits were not quite so large as is customary, there was a richness of colouration that easily rivals that of the fruit sent to us from America. A few exhibitors had evidently spent some time in polishing up their specimens, for they shone like burnished gold. It is probable that this polishing is carried a little too far, as we heard several visitors express the opinion that they looked as though they had just come from a fruiterer's shop. However, no one is likely to set up their fruits covered with travelling dust, so the chances are that the polishing will continue to hold the sway. An examination of the Apples showed many of them to be maggoty, which is exceedingly regrettable. Some magnificent Pears were shown as well by private as by professional growers, the colour of many of them being very rich, though as a rule the fruits were smaller than usual. In some of the smaller classes, for both Apples and Pears, the competition was remarkably keen, and the produce staged of excellent quality.

Of the kinds of fruits not yet mentioned the Grapes are the most important, and claim the greatest amount of individual attention. It cannot be said that these were of such high quality as it was thought would be staged; indeed, some of the bunches ought not to have found their way to the Palace. In many instances it is true the berries were of immense size, but the colouring and the finish were not, as a rule, up to the mark. Some of the Muscat of Alexandria were withered and very green, richly coloured berries being very rare. The Madresfield Court were, almost without exception, red at the stalk, while many of the Black Hamburghs were past their best, and rapidly losing colour. Gros Maroc was well staged as regards finish, but the same can hardly be said of Gros Colman, Mrs. Pearson, Lady Downe's, and one or two others. Can it be that exhibitors do not bring their best produce owing to the comparative smallness of the prizes? We trust such is not the case, but it certainly seems to point in that direction.

There is another point which has a very material effect on the value, or otherwise, of the show from an educational point of view, and that is the naming of the fruit. Every exhibition, whether it be of a horticultural nature or not, must be of value for the purposes of education, and the more correct the information the greater the value of the show. Bearing this in mind, we were extremely sorry to see so many names of Apples, Pears, and other fruits spelt wrongly. For example, one exhibitor had printed tickets, and we observed Apple Pott's Seedling instead of Potts', and Pear Nouveau Poitean, whereas it should have been Nouveau Poiteau, while a prominent grower had staged Pears Pitmaston Dutchess. These may seem trivial points, but several visitors copied the names as they were written, and of course there were many examples besides those mentioned. We trust that in the future every exhibitor will make perfectly sure that his cards are correctly inscribed, which may be easily done by consultation of some standard work on fruit. In staging plants and flowers the same rule ought always to be observed.

GARDENERS' AND AMATEURS' SECTION.

Collections.

The principal class in the first division, which included fruit grown either out of doors or under glass, was for a collection of twelve dishes of ripe dessert fruit of at least six kinds; only one Pine, one Melon, one dish of black and one of white Grapes allowed; not more than two varieties of any other kind, and no two dishes of the same variety. Mr. F. Harris, gardener to Lady Henry Somerset, Eastnor Castle, Ledbury, was adjudged the premier award of £7 10s. The stand comprised Grapes Muscat of Alexandria, good in berry but unfinished, and Gros Maroc, in splendid form; a good Smooth Cayenne Pine; Sea Eagle and Prince of Wales Peaches, in capital condition; King of the Pippins and Ribston Pippin Apples, Brunswick Figs, Coe's Golden Drop Plums, and a seedling Melon, with a dish of Nectarines and Pears. As a whole the exhibit was very creditable. Mr. J. H. Goodacre, gardener to the Earl of Harrington, Elvaston Hall, Derby, was a good second, his best dishes being Muscat of Alexandria Grapes, Souvenir du Congrès Pears, and American Mother Apple. Mr. J. McIndoe, gardener to Sir J. W. Pease, Bart., Hutton Hall, Guisborough, was a fair third.

There was a smaller class for a collection of eight dishes of ripe dessert fruit in at least four kinds, Pines being excluded. One Melon, one dish of black and one of white Grapes were allowed, but not more than two varieties of any other kind, and no two dishes of any one variety. Competitors in the larger class were not eligible to enter in this one, and about half a dozen staged. Mr. Geo. Reynolds, gardener to Messrs. De Rothschild, Gunnersbury Park, Acton, was a splendid first with a handsome exhibit. It comprised Grapes Muscat of Alexandria and Gros Maroc, Apple Ribston Pippin, Plum Coe's Golden Drop, Peaches Princess of Wales and Gladstone, a seedling Melon, and Nectarine Pineapple. The second position was adjudged to Mr. W. J. Empson, gardener to Mrs. Wingfield, Ampthill, who showed amongst others Grapes Black Alicante and Golden Queen, Fig Brown Turkey, and Pear Doyenné du Comice. Mr. W. Tidy, gardener to W. K. D'Arcy, Esq., Stanmore, was placed third.

Grapes and Figs.

Seven exhibitors came forward in the class for a collection of Grapes in six distinct varieties, two bunches of each, and in which it was com-

pulsory to include both black and white varieties. Here Mr. G. Reynolds, gardener to Messrs. De Rothschild, Gunnersbury Park, Acton, succeeded in annexing the first prize. The varieties represented were Black Hamburgh, which was losing its colour; Chasselas Napoleon, fine in berry; Gros Maroc, grandly finished bunches; Muscat of Alexandria, not very good, with Madresfield Court and Buckland Sweetwater, both of medium quality. The second position was assigned to Mr. W. Taylor, gardener to C. Bayer, Esq., Forest Hill, whose best varieties were Madresfield Court and Gros Colman. Mr. J. H. Goodacre was placed third, his examples of Black Alicante and Muscat of Alexandria being the most conspicuous.

In the class for six bunches in three distinct varieties, in which no exhibitor in the class immediately preceding was eligible to compete, Mr. F. Cole, gardener to Sir George Russell, Bart., Reading, went to the front with Muscat of Alexandria, Foster's Seedling, and Black Alicante. Mr. J. Jones, Cradley, was a fair second, and Mr. F. Harris third. The class for three bunches of Black Hamburghs was not particularly strong. Mr. W. Mitchell, gardener to J. W. Fleming, Esq., Romsey, was placed first; Mr. W. Taylor, Forest Hill, second, and Mr. G. Reynolds third. Mr. W. Taylor, Forest Hill, staged well in the class for Madresfield Court, his examples being good. Mr. W. Tidy, gardener to W. K. D'Arcy, Esq., Stanmore, was a capital second, and Mr. W. J. Empson, gardener to Mrs. Wingfield, Ampthill, Beds, third.

For three bunches of either Gros Colman or Gros Maroc, Mr. J. Jones, Ridgway Vineries, Cradley, Malvern, was placed first. His variety was Gros Colman; the bunches were ill-shaped and berries large, though not of high finish. Mr. G. Reynolds took the second prize with the same variety, followed by Mr. F. Cole with handsome bunches of Gros Maroc, in which the berries were perfectly finished, but small. Black Alicantes were very evenly shown, the prizewinners being Messrs. F. Cole, J. Bury, Petersham, and W. Howe, gardener to Henry Tate, Esq., Streatham, in the order given. The class for Lady Downe's was not very strong. The first prize fell to Mr. W. Tidy, the second to Mr. W. J. Empson, and the third to Mr. A. Kemp, Horsham. For three bunches of any other black Grape, Mr. W. Mitchell was first with Mrs. Pince; Mr. W. Smith, gardener to R. Ovey, Esq., Henley-on-Thames, second with Alnwick Seedling; and Mr. W. Tidy a very close third with the same variety.

Mr. F. Cole was first in the class for three bunches of Muscat of Alexandria, Mr. J. H. Goodacre being second, and Mr. G. Reynolds third. Neither of these exhibits was perfect. For three bunches of any other white Grape, Mr. G. Reynolds was the most successful with Chasselas Napoleon, followed by Mr. W. Taylor, Forest Hill, with Buckland Sweetwater; and Mr. G. Lane, gardener to Mrs. Ridge, Englefield Green.

FIG. 51.—MR. GEORGE WOODWARD.

A large number of dishes competed in the class for a dish of Figs of any variety, and some of the fruits were very handsome. The first position was awarded to Mr. W. Messenger, gardener to C. H. Berners, Esq., Woolverstone Park, Ipswich; the second to Mr. H. Folkes, gardener to C. E. Strahan, Esq., Hemel Hempsted; and the third to Mr. W. Mitchell. Each of these competitors staged Brown Turkey.

HARDY FRUITS.

For a collection of hardy fruit grown entirely in the open air, and to comprise not more than fifty dishes, the competition between Mr. G. Wythes, gardener to Earl Percy, Syon House, Brentford, and Mr. J. Powell, gardener to Colonel Brymer, M.P., Dorchester, was remarkably keen, the prizes going to them in the order they are here named. The winner's collection was distinctly more varied than his opponent's, while the fruits in each case were most creditable as regards quality. Amongst the best Apples Mr. Wythes staged were Wealthy, Cox's Orange Pippin, Lord Suffield, Small's Admirable, Warner's King, Lord Derby, Alfriston, Blenheim Orange, Ribston Pippin, and Cellini. The most noticeable Pears were Beurré Diel, Louise Bonne of Jersey, Beurré Bachelier, and Beurré Sterckmans. In addition to these there were two or three kinds of Nuts, with Grapes, Cherries, Plums, Peaches, and Damsons. Mr. J. Powell had some grand Apples and Pears, representing many of the leading varieties. The third position was assigned to Mr. Miller, gardener to Lord Foley, Ruxley Lodge, Esher; but his collection was decidedly behind the other two.

Mr. R. Potter, gardener to Sir M. Collet, Bart., Kemsing, Sevenoaks, secured the coveted premier award in the class for a collection of hardy fruit not exceeding thirty-six dishes, grown partly or entirely under glass, to illustrate orchard house culture. The exhibit was well diversified, and comprised some very handsome specimens. The Grapes were Foster's Seedling and Gros Maroc. Amongst the Pears, which were very fine, we noticed Doyenné du Comice, Marguerite Marillat, Pitmaston Duchess, Doyenné Boussoch, and Duchesse d'Angoulême, while the Apples comprised splendid examples of Emperor Alexander, Baldwin, Lady Henniker, King of Tompkins County, Cox's Orange Pippin, Worcester Pearmain, Ribston Pippin, Wealthy, and The Queen. Plums were represented by Automne Compôte, Coe's Golden Drop, and Bryanston Gage. In addition to these there were Figs, Peaches, and Nectarines in good form. Mr. J. McIndoe was a fine second, with a collection representative of good culture and careful selection. The same kinds of fruits were staged as in the preceding collection, but the varieties were, of course, slightly different.

COOKING AND DESSERT APPLES.

The first prize for twenty-four dishes of Apples, distinct, sixteen cooking and eight dessert, was secured by Mr. G. Woodward, gardener to R. Leigh, Esq., Barham Court, Maidstone, with a magnificent collection, every dish being almost perfect. The colouring was particularly attractive. The varieties were Ecklinville, Beauty of Kent, Warner's King, Peasgood's Nonesuch, Stone's (grand) Belle Dubois, Cox's Pomona, Brabant Bellefleur, Bismarck, Mère de Ménage, Alfriston, Emperor Alexander, Tower of Glamis, American Mother, Allington Pippin, Cox's Orange Pippin, Baumann's Red Reinette, Washington, Ribston Pippin, Calville Rouge, and Gascoyne's Seedling. Mr. C. A. Bayford, gardener to C. Lee Campbell, Esq., Glewstone Court, Ross, was second with a creditable collection, though visibly weaker than the former. The best dishes were Peasgood's Nonesuch, Warner's King, Lord Derby, American Mother, Ribston Pippin, Tyler's Kernel, Stirling Castle, Crimson Queening, Potts' Seedling, Cox's Orange Pippin, Duchess' Favourite, and King of the Pippins. Mr. G. Goldsmith, gardener to Sir E. G. Loder, Bart., Leonardslee, Horsham, was placed third with a good, well coloured collection. The best dishes were Flower of Kent, Hollandbury, Peasgood's Nonesuch, Wealthy, and Ribston Pippin. There were six competitors in this class, which it will readily be understood was a most interesting one.

The class for twelve dishes of Apples, eight cooking and four dessert, brought the same number of exhibitors as the preceding one. Here, again, the fruit staged was, as a rule, of splendid quality. Mr. W. G. Pragnell, gardener to J. K. Wingfield Digby, Esq., Sherborne Castle, Sherborne, was placed first with an even exhibit, including Lord Derby, Peasgood's Nonesuch, Warner's King, New Hawthornden, Annie Elizabeth, Bismarck, Emperor Alexander, Alfriston, Sturmer Pippin, Cox's Orange Pippin, Ribston Pippin, and King of the Pippins. Mr. B. Miller, gardener to T. W. Startup, Esq., West Farleigh, Maidstone, occupied the second position. Warner's King, Tower of Glamis, The Queen, Cox's Pomona, Gascoyne's Seedling, and Worcester Pearmain were his best dishes. The third prize went to Mr. J. Hill, gardener to C. R. W. Adeane, Esq., Babraham Hall, Cambridge, who showed good examples of Sandringham, Peasgood's Nonesuch, and King of the Pippins.

Mr. W. Slogrove, gardener to Mrs. Crawford, Gatton Cottage, Reigate, was placed first for nine dishes, six cooking and three dessert. The varieties were Warner's King, Peasgood's Nonesuch, Sandringham, Emperor Alexander, Stone's, Cox's Pomona, Washington, Worcester Pearmain, and Cox's Orange Pippin. Mr. T. W. Herbert, gardener to J. T. Charlesworth, Esq., Nutfield Court, Redhill, was second with good dishes of The Queen, Gloria Mundi, and Cox's Orange Pippin.

COOKING APPLES.

For six dishes of cooking Apples Mr. G. Woodward was again placed first with a splendid exhibit. Warner's King, Stone's, Peasgood's Nonesuch, Lord Derby, Emperor Alexander, and Mère de Ménage were the varieties staged. Mr. W. Lewis, gardener to T. Oliverson, Esq., East Sutton Park, Maidstone, was placed second with good dishes of Peasgood's Nonesuch, Mère de Ménage, Warner's King, and Belle Dubois. Mr. A. H. Rickwood, gardener to the Dowager Lady Freake, Fulwell Park, Twickenham, was third with a very clean exhibit.

For three dishes, distinct, Mr. G. Goldsmith secured premier honours with an exceptionally fine exhibit, showing Peasgood's Nonesuch, Warner's King, and Lord Derby. Mr. J. Powell, gardener to Col. Brymer, M.P.,

Ilsington House, Dorchester, was second with the same varieties. Mr. A. Brook, Mereworth, was third. For six dishes of Bramley's Seedling, Mr. W. King, gardener to J. Colman, Esq., Gatton Park, Reigate, was placed first; Mr. J. Turton, gardener to J. Hargreaves, Esq., Maiden Erleigh, Reading, second; and Mr. H. H. Hurnard, Gurney Manor, Higham, third.

Dessert Apples.

The class for six dishes of dessert Apples brought out eight competitors, Mr. G. Woodward being first with a grand exhibit. The varieties were Gascoyne's Scarlet Seedling, Washington, Baumann's Red Reinette, Ribston Pippin, American Mother, and Cox's Orange Pippin. Mr. B. Miller was placed second with good dishes of Worcester Pearmain, Cox's Orange Pippin, Ribston Pippin, and King of the Pippins. Mr. G. Goldsmith third, with smaller, but well coloured, fruits.

For three dishes of dessert Apples Mr. C. A. Bayford was first with King of the Pippins, Washington, and Ribston Pippin; Mr. A. Kemp, gardener to C. R. Scrase Dickens, Esq., Coolhurst, Horsham, second with good Ribston Pippin, Cox's Orange Pippin, and American Mother; Mr. R. Potter, gardener to Sir Mark W. Collet, Bart., Kemsing, was third. There were eleven competitors in this class.

Pears.

Six competitors contested the class for twelve dishes of Pears, Mr. G. Woodward securing the premier place with a grand exhibit. The varieties comprised Marie Benoist, Durondeau, Pitmaston Duchess, Doyenné du Comice, Emile d'Heyst, Beurré Hardy, Duchesse d'Angoulême, Princess, Gansel's Bergamot, Doyenné de Merode, Beurré Superfin, and Beurré Baltet. Mr. G. Goldsmith followed with a worthy display, his best dishes being Marguerite Marillat (grand), Beurré Bachelier, Pitmaston Duchess, and Doyenné Boussoch. Mr. J. Powell was third.

Mr. W. Cotterell, gardener to Sir W. N. M. Geary, Bart., Tonbridge, was first for nine dishes of dessert Pears in a good competition, showing Beurré Bosc, Pitmaston Duchess, Duchesse d'Angoulême, Durondeau, Beurré Superfin, Beurré Rance, Beurré Hardy, Louise Bonne of Jersey, and Gansel's Bergamot. Mr. W. Jones, gardener to G. Brougham, Esq., Wallington Bridge, Carshalton, was a very close second. Beurré Bachelier, Pitmaston Duchess, Duchesse d'Angoulême, Madame Treyve, and Beurré Superfin were well shown. Mr. A. H. Rickwood was third with creditable dishes of Beurré Superfin, Durondeau, and Beurré Hardy.

In the competition for six dishes of dessert Pears, Mr. W. Messenger, gardener to C. H. Berners, Esq., Woolverstone Park, Ipswich, was easily first with very fine dishes of Pitmaston Duchess, Beurré Baltet Père, Doyenné du Comice, Durondeau, Beurré Hardy, and Louise Bonne of Jersey. Mr. W. Slogrove was placed second with good even dishes, the best of which were Pitmaston Duchess, Beurré Superfin, and Doyenné Boussoch. Mr. A. Basile, gardener to the Rev. O. L. Powels, Woburn Park, Weybridge, was third, Durondeau and Pitmaston Duchess being most noticeable in his stand.

Mr. R. Edwards, gardener to G. N. Field, Esq., Beechy Lees, Sevenoaks, was first for three dishes of dessert Pears with Pitmaston Duchess, Doyenné du Comice, and Madame Treyve. Mr. Geo. Fennell, gardener to W. M. Cazalet, Esq., Fairlawn, Tonbridge, was second with very fine dishes of Marguerite Marillat and Pitmaston Duchess. Mr. C. Harris, gardener to O. A. Smith, Esq., Hammerwood, East Grinstead, was third.

The competition for three dishes of cooking Pears was limited to four exhibitors, Mr. G. Woodward securing first prize with Grosse Callabasse (good), Triomphe de Joidoigne, and Catillac. Mr. G. Goldsmith was second, and Mr. R. Chamberlain, gardener to F. M. Lonergan, Esq., Reading, third. The chief prize for one dish of cooking Pears was secured by Mr. C. Harris with a grand dish of Catillac; Mr. H. Beames, gardener to H. Stock, Esq., Petersham, being second with Uvedale's St. Germain, and Mr. John Webb, gardener to H. Padwick, Esq., Horsham, third.

Peaches and Nectarines.

There were ten competitors for the three dishes of Peaches. Mr. Woodward was well ahead with Sea Eagle, Nectarine Peach, and Princess of Wales. Mr. F. Harris, gardener to Lady H. Somerset, Eastnor Castle, Ledbury, was second with a very even display. Mr. W. Mancey, gardener to Mrs. Druce, Merstham, was third. Mr. W. Mitchell, gardener to J. W. Fleming, Esq., Romsey, received the premier award for a single dish with a fine exhibit of Sea Eagle. Mr. G. Lane, gardener to Miss Ridge, Englefield Green, was second with Stirling Castle; and Mr. G. Goldsmith third with Sea Eagle.

Mr. F. Harris was the only exhibitor of three dishes of Nectarines, and was awarded first prize. Mr. W. Strugnell, gardener to the Right Hon. W. H. Long, M.P., Trowbridge, was first for a single dish with Victoria. Mr. J. Hill was second with Pineapple; and Mr. P. Bradley, gardener to F. W. Morter, Esq., Byfleet, third.

Plums.

A very good display of Plums was brought together. For four dishes of dessert varieties Mr. H. Folkes, gardener to C. E. Strachan, Esq., Hemel Hempstead, was first with Coe's Golden Drop, Reine Claude de Bavay, Late Transparent Gage, and Cloth of Gold. Mr. J. Vert, gardener to Lord Braybroke, Saffron Walden, was second; and Mr. Strugnell third. Mr. J. Vert was first for a single dish of a dessert variety with Coe's Golden Drop. Mr. J. Turton was second with the same variety, and Mr. W. Lewis third. There were about a dozen and a half dishes staged.

Cooking Plums were well represented, in spite of the scarcity this season. Mr. J. H. Goodacre, gardener to the Earl of Harrington, Derby, was first for four dishes, with good examples of Archduke, Monarch, Goliath, and Pond's Seedling. Mr. C. Sim, gardener to T. Gooch, Esq., Hemel Hempsted, was second, and Mr. Jas. Day, gardener to the Earl of Galloway, Garliestown, N.B., third. In the class for one dish of cooking Plums Mr. B. Osborn, gardener to Rev. H. G. Palmer, Reading, was first with a grand dish of "Le Mott Sang;" Mr. C. Sim was second, and Mr. J. H. Goodacre third.

Mr. W. Messenger was placed first for a single variety of Gage Plums with a fine dish of Reine Claude de Bavay. Mr. Herrin, gardener to Lady L. Fortescue, Dropmore, was second with Brahy's Late Gage, and Mr. B. Osborn third. Mr. G. Fennell exhibited the only collection of Damsons and Bullaces, and was awarded the first prize.

Apples and Pears—Single Dishes.

The competition in the many single dish classes for Apples and Pears is generally the keenest in the show, and this proved to be no exception in this respect. There were over a dozen competitors in the classes for some of the most popular varieties, and it is almost needless for us to say that many of the specimens were of the very finest quality. Perhaps they were not quite so large as some we have seen, but this is accounted for by the season. Colour and form were, however, both splendid, and the section as a whole was one of the most interesting in the exhibition.

Adams' Pearmain was splendidly staged by Mr. W. Camm, gardener to the Duchess of Cleveland, Battle Abbey. The specimens were of fine form and colour. Mr. G. Goldsmith was a capital second, and Mr. G. Woodward third. Mr. J. Powell went to the front with Allen's Everlasting, and was followed by Messrs. W. H. Godden, Sawbridgeworth, and J. Spottiswoode, Brighton, who were second and third in the order here given. The several dishes of Baumann's Red Winter Reinette made a particularly handsome display, as almost all the specimens were finely coloured. Mr. J. McKenzie, gardener to F. S. W. Cornwallis, Esq., Linton Park, Maidstone, was a creditable first; Mr. C. Ross, gardener to Captain A. J. Carstairs, Welford Park, Newbury, a good second, and H. C. Prinsep, gardener to Viscountess Portman, Buxted Park, Uckfield, third. The class for Blenheim Orange was, of course, very strong. The first prize went to Mr. W. H. Godden, the second to Mr. G. Chambers, Moorcock's Farm, Mereworth, and the third to Mr. W. King, each of whom showed well. Messrs. G. Woodward, H. C. Prinsep, and W. H. Godden secured the prize in the order named for a dish of Brownlees' Russet, while for Claygate Pearmain this order was maintained by the same competitors. The class for Court Pendû Plat was an attractive one. Mr. J. Tallack, gardener to E. Dresden, Esq., Livermere Park, Bury St. Edmunds, was a fine first; Mr. C. Ross, second, and Mr. R. Chamberlain, third, both staging well.

Amongst the score or so of dishes staged in the class for Cox's Orange Pippin there were some splendid specimens, good alike in form, colour, and size. The premier dish was staged by Mr. W. Messenger, who was followed by Mr. W. King and Mr. G. Woodward in the order named. Mr. B. Miller was first in the class for Egremont Russet, the only other contributor being Mr. G. Goldsmith, who received the second prize. For Fearn's Pippin the number of exhibits exceeded a dozen, and some very beautiful fruits were noticed. Mr. J. C. Tallack had a grand first prize dish, and was followed pretty closely by Mr. J. McKenzie, and Mr. W. King, gardener to G. R. Brougham, Esq., Carshalton Bridge. Mr. J. McKenzie went to the first position of the half dozen exhibitors of Gascoyne's Scarlet Seedling. The second prize was taken by Mr. J. Hudson, gardener to L. de Rothschild, Esq., Gunnersbury House, and the third by Mr. G. Woodward. As may be imagined this display was strikingly beautiful owing to the brilliance of colour possessed by this variety. Mr. J. C. Tallack's premier dish of King of the Pippins was quite perfect, while those of Mr. J. Powell and Mr. C. A. Bayford were not very far behind. There were quite eighteen dishes staged. In the class for a dish of King of Tompkins County, Mr. T. Turton, gardener to J. Hargreaves, Esq., Maiden Erleigh, Reading, was first with handsome fruits. Mr. J. C. Tallack was second, and Mr. J. Hill third. Mabbot's Pearmain only brought forth two competitors, Messrs. J. McKenzie and H. C. Prinsep, who were respectively first and second.

The prizes offered for Mannington's Pearmain were much more keenly contested, there being six or seven dishes shown. Mr. G. Woodward was a fine first, Mr. J. McKenzie second, and Mr. T. Turton third. Half a score came forward with Margil, and the dish which won for Mr. G. Woodward the first prize was a grand one; the second prize went to Mr. J. McKenzie, and the third to Mr. C. A. Bayford, each of whom showed very creditably. American Mother made a conspicuous class, though only half a dozen dishes were staged. Mr. C. A. Bayford was an undisputed first, Mr. J. McKenzie being second, and Mr. G. Goldsmith third. As usual, that old favourite Ribston Pippin was in great force, upwards of a score of dishes being staged, many of them of more than average excellence. Mr. G. Woodward was a grand first, Mr. J. McKenzie an exceptionally close second, and Mr. C. A. Bayford third. Mr. J. Hudson, who staged Scarlet Nonpareil in practically perfect form, was accorded the first prize, the second going to Mr. C. Ross, who also showed well; and the third to Mr. J. Hill. The prizewinners in the class for Sturmer Pippin were Messrs. W. G. Pragnell, R. Chamberlain, and C. Ross, each showing well. About eighteen brought Worcester Pearmain, and these made a most attractive class. Mr. W. King was first with beautiful specimens; Mr. G. Woodward second, and Mr. W. Messenger third. The class for a single dish of any other variety was a very strong one, some twenty-four dishes being exhibited. Mr.

J. McKenzie was first with handsome fruits of St. Edmund's Pippin; Mr. G. Goldsmith second, with Gravenstein in fine character; and Mr. G. Woodward third, with excellent fruits of Washington.

Alfriston was the first in the schedule of the single dishes of cooking Apples, and of it some fine specimens were shown. Mr. J. McKenzie was a splendid first, Mr. G. Woodward a good second, and Mr. W. Lewis, gardener to J. Oliverson, Esq., East Sutton Park, Maidstone, third. It will be observed that though about seven dishes were staged, all the prizes went into the Maidstone district. Mr. R. Cbamberlain staged Beauty of Kent in capital form, and received the premier award. He was followed by Mr. G. Woodward and Mr. A. Basile, gardener to the Rev. O. L. Powells, Weybridge. There were nearly a dozen exhibits of Bismarck, and the beautiful fruits shown by Mr. J. McKenzie thoroughly deserved the first prize that was awarded to them. Mr. G. Woodward also staged handsomely for the second prize, while Mr. C. Ross' third prize dish was not a great deal inferior. Bramley's Seedling was a comparatively small class, only four dishes being staged, but as all were good, quality made up for quantity. Mr. C. A. Bayford was first, Mr. S. Lyon, gardener to J. Salmon, Esq., Rowton, Chester, second, and Mr. J. Hill third. Cellini was staged largely and well. Mr. G. Goldsmith was first with magnificently coloured fruits, Mr. C. A. Bayford second with almost equally good specimens, and Mr. J. Powell third. The seventeen or eighteen dishes of Cox's Pomona made a very handsome collection. Mr. J. McKenzie's first prize fruits were exceptionally brigbt; while Mr. J. Powell, second, and Mr. G. Goldsmith, third, both showed well. Duchess of Oldenburg did not make a particularly good class, as the specimens were so very divergent in character. Mr. J. Culton, Castle Douglas, N.B., was a good first; Mr. T. W. Herbert, gardener to J. Charleswortb, Esq., Redhill, being second; and Mr. G. Goldsmith third.

Tbe justly popular Wellington, or Dumelow's Seedling, was magnificently staged. There were nearly eighteen dishes, out of which the wonderfully fine examples shown by Mr. J. McKenzie were selected for the first prize. Mr. W. G. Pragnell, also showing well, was placed second, and Mr. C. A. Bayford third. Very attractive were tbe Ecklinville Seedling exhibited by Mr. J. McKenzie, and for which he received the premier award. Mr. J. Spottiswoode was second with fine examples, and Mr. G. Woodward third. Very bright were the fruits of Emperor Alexander in the class for that variety. Mr. J. McKenzie's specimens were clean, of good shape, and beautifully coloured. Mr. G. Woodward was second, and Mr. G. Goldsmith third, each showing in a highly creditable manner. Mr. J. McKenzie secured the premier position in the class for Frogmore Prolific out of half a dozen exhibits. Mr. C. A. Bayford was second, and Mr. W. G. Pragnell third. The shapely fruits of Golden Noble made a fine display. Tbere were about a dozen exhibitors, of whom Mr. G. Chambers was adjudged to have the best examples. Tbe second and third prizes went to Messrs. G. Woodward and J. McKenzie respectively. Golden Spire was not so numerously shown. Mr. G. Woodward's first prize dish were of exceptional quality. Mr. G. Goldsmith was second, and Mr. W. Lewis third. There were only three dishes of Grenadier, staged by Messrs. C. Herrin, W. Lewis, and J. Hill, who secured the prizes in the order given. New Hawthornden again made a small class. Mr. G. Woodward staged well for the first prize, and was followed by Mr. A. Brooks, Mereworth, and Mr. T. W. Herbert as mentioned. Mr. J. McKenzie was first, and Mr. J. Hill second, for Hormead Pearmain, of which they were the only exhibitors.

Rather over a dozen dishes were brought of the highly appreciated Lane's Prince Albert, and it is superfluous to add some grand examples were shown. Mr. C. Ross, for the premier prize, staged well coloured fruits of great size. Mr. C. A. Bayford was second with good specimens, and Mr. G. Woodward was third. Lord Derby was magnificently shown by Mr. G. Fennell, gardener to W. Cazalet, Esq., Fairlawn, Tonbridge, who was accorded the chief prize. Mr. R. Edwards, gardener to G. Field, Esq., Beechy Lees, Otford, was a creditable second, and Mr. C. Herrin third. Lord Grosvenor was not largely shown, but better examples than those of Mr. G. Woodward, wbo took the first prize, need not be wished for. Mr. C. Herrin was second, and Mr. F. Harris third. Lord Suffield was more numerous, over a dozen contestants bringing fruits. Mr. J. McKenzie annexed the first prize with wonderfully fine specimens, and was followed by Mr. G. Woodward and Mr. R. Chamberlain, each showing in good form. Mère de Ménage was magnificently exhibited as regards quality, but not quantity, only seven exhibitors coming forward. Mr. J. McKenzie was a grand first prizewinner, Mr. C. Ross a good second, and Mr. G. Woodward a capital third. The palm to any individual variety in the show must go to the renowned Peasgood's Nonesuch, which was staged by nine different growers, most of whom were in grand form. Mr. J. McKenzie deserved his first prize, for the fruits were far above average quality. Mr. W. A. McKenzie, gardener to the Bishop of Bath and Wells, Tbe Palace, Wells, was a splendid second; and Mr. G. Powell, The College, Swanley, a good third.

Messrs. J. R. Pearson & Sons, Chilwell, offered generous prizes in two classes for Newton Wonder, but in neither instance was the competition good. In the first case the class was confined to growers in the counties of Cardigan, Radnor, Salop, Stafford, Warwick, Northampton, Bedford, Cambridge, Essex, and north thereof. From such an enormous area only two competitors came, these being Mr. J. Hill, Babraham Hall; and Mr. H. H. Hurnard, Higham, who received the first and second prizes. In the other class, open to exhibitors south of the counties named above, there were four dishes shown. Mr. R. Edwards was placed first, Mr. G. Goldsmith second, and Mr. J. Harris, gardener to P. Crowley, Esq., Waddon House, Croydon, third. The specimens were of fair quality throughout. Almost a dozen dishes of Potts' Seedling were shown, and very beautiful were many of the fruits. Mr. T. Turton was a fine first, Mr. G. Woodward a good second, and Mr. J. Hudson third. Nine exhibitors showed Sandringham, and Mr. J. McKenzie was accorded tbe leading position with grand fruits. Mr. G. Wythes, gardener to Earl Percy, Syon House, Brentford, was a splendid second; and Mr. C. Ross a good third. Of Spencer's Favourite only four dishes were shown, that belonging to Mr. G. Woodward being the best. Mr. W. Jones was second, and Mr. B. Miller third. Stirling Castle was staged up to its best standard by Mr. J. McKenzie, who secured the first prize from about nine opponents. Mr. W. Strugnell, gardener to the Hon. W. H. Long, Rood Ashton Park, Trowbridge, was a creditable second; and Mr. W. King a fair third.

Mr. J. McKenzie went to the front in the class for a dish of Stone's Apple or Loddington Seedling, and was followed by Messrs. G. Woodward and A. Brooks in the order named. Of The Queen some very handsome fruits were staged, especially by Mr. J. McKenzie, who was again first. Mr. G. Woodward was second, and Mr. C. Herrin third. Mr. J. McKenzie's dish of Tower of Glamis was perfect. Mr. A. Brooks was second, and Mr. C. A. Bayford third. In all eight dishes of this variety were staged. Three exhibitors only showed Tyler's Kernel, these being Messrs. J. McKenzie, J. Hill, and A. Basile, who received the prizes in the order in which their names are given. Some two dozen growers brought Warner's King, and it will be admitted that many fine fruits were seen. Mr. J. McKenzie was again first, Mr. G. Chambers second, and Mr. G. Woodward third, all the prizes going to exhibitors from within a short distance of Maidstone. There were about a dozen and a half of competitors in the class for a dish of any other variety, and Dutch Codlin from Mr. J. McKenzie secured the first prize. Mr. W. Camm was second with Lady Henniker in good character, and Mr. G. Fennell third with Castle Major.

Pears.

Turning now our attention to the Pears we found there were upwards of thirty classes devoted to them, and in almost all of which there were exhibits. In some of the classes the numbers staged were very large, and the competition remarkably keen; whilst in others there were only two or three dishes shown. As a whole the quality was good throughout, though tnere were occasional specimens of more than average merit, and a few considerably below it. Many varieties were represented by specimens clean in the skin, of perfect form, and very beautiful in colour. Below will be found the names of the prizewinners in the major portion of the classes, but not in those where tbere were only one or two competitors.

Tbe first to be examined was Bergamotte Esperen, in the class for which we found about eight dishes of varying qualities. Mr. J. Powell secured the premier position with shapely fruits, and was followed by Mr. C. Ross in the second position, and Mr. G. Woodward in the third. About the same number of exhibits of Beurré Bosc were tabled. Mr. G. Goldsmith was a capital first; Mr. W. Cotterell, gardener to Sir W. N. Geary, Bart., Tonbridge, second; and Mr. B. Osborn, gardener to the Rev. H. G. Palmer, Holme Park, Reading, third. Of Beurré Diel there were upwards of a dozen exhibitors, and several of them staged in handsome form. Mr. G. Woodward secured the first prize with large shapely specimens; Mr. G. Wythes was a very close second, and Mr. G. Goldsmith third. Some fine dishes were to be seen in the class for Beurré Hardy, the first prize being taken by Mr. G. Woodward with good fruits; Mr. H. C. Prinsep was second, and Mr. W. Messenger third. There were seven or eight dishes staged. One of the most popular classes was that devoted to the luscious Beurré Superfin, of which eleven dishes were shown. Mr. G. Woodward showed splendidly for the first position, as did Mr. G. Goldsmith, who was second. Mr. J. Webb, gardener to H. Padwick, Esq., Manor House, Horsham, was third. The only exhibitors of Comte de Lamy were Messrs. T. Turton, T. W. Herbert, and G. Goldsmith, to whom the prizes were awarded in the same order as the names are given here.

Five contestants came forward with Conference, and Mr. G. Woodward, with specimens in excellent character, was adjudged tbe leading position. Mr. W. Slogrove, gardener to Mrs. Crawford, Gatton Park, Reigate, was a good second; and Mr. J. Powell third. Conseiller de la Cour was represented by about half a dozen dishes, the best of which was exhibited by Mr. J. C. Tallack, who was in splendid form. The second prize was won by Mr. A. Basile; and the third by Mr. C. A. Bayford. The highly esteemed Doyenné du Comice brought out nearly a dozen exhibitors, some showing strongly, while others were a trifle weak. Mr. J. Powell was a grand first; Mr. B. Calvert, gardener to Col. Archer Houblon, Bishop's Stortford, a good second; and Mr. G. Woodward third. A splendid display was made by the eight dishes of Durondeau, which was exceptionally well shown. Mr. G. Woodward, with beautiful examples, was first; Mr. W. G. Pragnell second; and Mr. W. Cotterell third. Of the six or seven competitors staging Easter Beurré Mr. B. Calvert was placed in the highest position with typical specimens. Mr. G. Woodward was a good second, and Mr. J. Powell third. There were only three competitors in the class for Emile d'Heyst, and of these Mr. G. Woodward was a good first, followed by Mr. W. Strugnell and Mr. G. Goldsmith. Tbe exhibits of Fondante

d'Automne again were not numerous, there being four only. Mr. A. Basile, staging well, took the first award ; Mr. T. Turton the second ; and Mr. G. Goldsmith the third.

Mr. G. Woodward, with superb fruits, took the chief prize in the class for Fondante de Thirriott, Mr. W. Messenger being second, and Mr. J. Nicholson, gardener to J. Melles, Esq., Sewardstone Lodge, Chingford, third. Of Glou Morçeau some grand fruits were staged by several of the nine competitors, who were headed by Mr. J. Powell with well-nigh perfect specimens. Mr. G. Woodward was a highly creditable second, and Mr. B. Calvert a good third. Rather over a dozen dishes were shown in the class for Josephine de Malines, and it is almost superfluous to say that amidst such an array there were some splendid fruits. Mr. J. Powell was first with a fine dish, and was followed by Mr. T. W. Herbert and Mr. B. Calvert in the order named. There were about ten dishes of Louise Bonne of Jersey, and several of the fruits were exceptionally good in colour. The splendid specimens shown by Mr. J. Coles, gardener to H. Walker, Esq., Balcombe, Sussex, gained the premier prize. Mr. W. Messenger was second, and Mr. G. Goldsmith third, each showing in highly creditable form. Three exhibitors came forward with Marie Benoist, and of these Mr. G. Woodward was adjudged to have the finest examples. The second position was occupied by Mr. W. Messenger, and the third by Mr. G. Wythes. The newer Marguerite Marillat was only represented by two dishes, but these were both of splendid quality. Mr. G. Goldsmith was first, and Mr. R. Edwards second.

Needless to say Marie Louise was shown in fine form by several of the ten competitors. Mr. B. Osborn was a splendid first, Mr. G. Woodward a comparatively close second, and Mr. G. Goldsmith a good third. About half a dozen dishes of Marie Louise d'Uccle were shown, the best coming from Mr. W. Cotterell. Mr. G. Woodward was a good second, and Mr. G. Goldsmith third. Mr. G. Woodward was the most successful of the five exhibitors of Nouvelle Fulvie, followed by Mr. G. Goldsmith and Mr. G. Wythes in the order named. Only three or four dishes of Olivier des Serres were staged. Mr. G. Goldsmith took the leading position, Mr. G. Woodward the second, and Mr. J. Nicholson the third. One of the very best classes in the Pear section was that for Pitmaston Duchess, and amongst the dozen dishes staged there were several of superb quality. Mr. W. Cotterell was a grand first. Mr. G. Woodward a splendid second, and Mr. C. Harris, gardener to O. A. Smith, Esq., East Grinstead, a good third. Mr. C. Ross was a decided first of the trio who showed Seckle. Mr. T. Turton was second, and F. Harris third. Of Thompson's, four or five dishes were exhibited, the prizewinners being Messrs. J. Powell, W. Cotterell, and W. Slogrove. A splendid dish gained Mr. G. Woodward the first prize for Winter Nelis. Mr. G. Goldsmith was a good second, and Mr. F. Harris third. There were twelve competitors. In the class for any other variety Mr. G. Woodward was first with Gansel's Bergamot in superb form, Mr. J. Spottiswoode second with fine Duchesse d'Angoulême, and Mr. G. Goldsmith third with Rivers' Princess. About a dozen and a half exhibitors competed in this class.

NURSERYMEN'S SECTION.

In this section, which was confined to nurserymen, there were seven classes, and there were exhibits in all but one of these. The classes were considerably larger than the majority of those in the section with which we have already dealt ; but, of course, there were not nearly so many contestants in each. Of the most magnificent quality was a considerable proportion of the fruit exhibited, and these few classes alone made a beautiful and exceedingly interesting display. Instead of money prizes, medals of the Royal Horticultural Society were given in this section. The class in which there was no competition was that for a collection of fruit-bearing branches or sprays of any kind or variety of various fruit bushes or trees, to occupy a table not exceeding 24 feet by 3 feet.

The first class scheduled was for a collection of fruit trees bearing fruit in pots, and to which a footnote was added, permitting exhibitors to place gathered fruits or nuts between the pots, but of which no notice was to be taken by the Judges. Messrs. T. Rivers & Son, Sawbridgeworth, were the only exhibitors in the class, and they were rightly adjudged the gold medal. The trees were beautiful in shape, and were carrying grand crops of fruits. The Apples included Bismarck, Bramley's Seedling, and Cox's Pomona ; while Pears were grandly represented by Charles Ernest, Pitmaston Duchess, Conference, Durondeau, Bergamotte Esperen, Doyenné du Comice, and several others. Besides these there were Plum Coe's Golden Drop and Peach Golden Eagle, with some Crabs. Taking advantage of the permission conveyed in the schedule, the space between the pots was very profitably occupied. Beneath a bell-glass was a specimen of Pitmaston Duchess, which the ticket told us weighed 2 lbs., and which was the subject of much admiration from the visitors. The Grapes staged were quite as good as any in the show as regards colour and finish. There were bunches of Golden Queen, Muscat of Alexandria, Gros Maroc, and Black Alicante, each in fine condition. Then there were Peaches Golden Eagle and Lady Palmerston, with Plums Coe's Golden Drop, Rivers' Primate, Jefferson, Grand Duke, and Golden Transparent. Besides these we noted some splendid Apples, including Peasgood's Nonesuch in grand character, Emperor Alexander, King of Tompkins County, Cox's Orange Pippin, Ribston Pippin, Washington, and Worcester Pearmain, with such Pears as Souvenir du Congrès, Doyenné du Comice, and Louise Bonne of Jersey in the best of condition. It was a matter for regret that this was the only exhibit in the class, as the more competition there is the more instructive and interesting an exhibition becomes.

Messrs. G. Bunyard & Co., Royal Nurseries, Maidstone, were the only exhibitors in the class for a collection of hardy fruits grown partially or entirely under glass, to illustrate orchard house culture, and a very handsome and creditable display they succeeded in making. As representing the first prize a silver-gilt medal was awarded. Running the whole length of the centre of the table were fruit trees in pots, and these showed evidences of excellent culture. There were Grapes, Apples, Pears, and Figs. But it was amongst the fruits in the dishes that the very best specimens in the exhibit were to be observed, some of them being of magnificent quality. Such Apples as Wadhurst Pippin, King of Tompkins County, Worcester Pearmain, Peasgood s Nonesuch, Cox's Orange Pippin, Warner's King, Gascoyne's Scarlet Seedling, Potts' Seedling, Belle de Pontoise, Lady Sudeley, Gloria Mundi, American Mother, Lane's Prince Albert, Grenadier, Emperor Alexander, Stone's, Wealthy, Washington, Golden Noble, Twenty Ounce, Cox's Pomona, and The Queen were in exceptionally good form. The best of the several Pears were Duchesse d'Angoulême, Doyonné Boussoch, Souvenir du Congrès, Doyenné du Comice, Pitmaston Duchess, Marguerite Marillat, Conference, Marie Louise, Beurré Fouqueray, and Marie Benoist. In addition to these there were Grapes, Figs, and Tomatoes in dishes. As usual in the Maidstone fruits the colours were marvellously rich and clear.

Following up their success in the preceding class Messrs. Bunyard and Co. annexed the gold medal in the class which, to quote the schedule, was for a "collection of not less than seventy-five, or more than 100 distinct varieties of hardy fruits, in baskets or dishes, grown entirely in the open air ; to be arranged on a table of about 24 feet by 6 feet, or an equivalent space ; foliage plants may be added, and branches of any fruit-bearing trees or bushes." The exhibit was undeniably a handsome one, but there was a suspicion of formality in the piles of fruit that occurred at intervals, and each of which was surmounted by a Palm. Again the quality was of the very best, and well worthy of the firm. Although several varieties of Apples were the same as in the foregoing class, we observed in particularly good condition Bismarck, Royal Jubilee, James Grieve, Cornish Giant, Allington Pippin (splendid), Bramley's Seedling, King of the Pippins, Mrs. Barron, Grenadier, Col. Vaughan, Baumann's Red Winter Reinette, Yorkshire Beauty, and Newton Wonder. Of Pears there were Beurré Hardy, Beurré Superfin, Beurré Diel, Nouveau Poiteau, Doyenné Boussoch, Pitmaston Duchess, Gansel's Bergamot, Souvenir du Congrès, Conference, and Marie Louise. Mr. H. Berwick, Sidmouth, received the second prize. His collection was comprised of most of the leading varieties of Apples and Pears, the former predominating. In shape and colour the Sidmouth Apples were wonderfully good.

The silver-gilt medal offered as a first prize in the class for a collection of not less than thirty, or more than fifty distinct varieties of hardy fruits, in baskets or dishes, grown entirely in the open air, to be arranged on a table of about 24 feet by 3 feet, or an equivalent space, and to which foliage plants might be added, and branches of any fruit-bearing trees or bushes, was well won by Mr. J. Colvill, The Nurseries, Sidmouth. The second prize was taken by Mr. A. Wyatt, Hatton, Middlesex, who was the only other exhibitor. Amongst his Apples Mr. Colvill staged Mère de Ménage, Cox's Pomona, New Hawthornden, Beauty of Kent, Lane's Prince Albert, Worcester Pearmain, Lord Suffield, Newton Wonder, The Queen, and Gascoyne's Scarlet Seedling. Of Pears the following varieties were represented—Brockworth Park, Pitmaston Duchess, Grosse Calebasse, Marie Louise, and Beurré Clairgeau, while in addition there were Plums, Peaches, and Medlars. The fruit in this stand again was richly coloured.

Mr. H. Berwick was apparently the only exhibitor in the class for a collection of not less than thirty or more than fifty distinct varieties of Pears. They had to be staged either in baskets or dishes, and must have been grown entirely in the open air. The table space allowed was 24 feet by 3 feet, and foliage plants or branches of fruits were permissible. The specimens were not, as a rule, very large, but they were clean, even, and of good colour. Amongst others noted were Durondeau, Fertility, Pitmaston Duchess, King Edward, Doyenné Boussoch, Beurré Capiaumont, Brown Beurré, Beurré Clairgeau, Beurré Diel, Autumn Bergamot, and Beurré Superfin. The first prize was a silver-gilt medal.

In a similar class for Apples, the silver-gilt medal went to Mr. John Basham, Fair Oak Nurseries, Bassaleg, Newport, Mon., who staged some superb examples, excellent alike in colour and in shape. Though some varieties were not, of course, quite so good as others, there was scarcely a weak dish in the whole exhibit. Amongst the best were Tyler's Kernel, Warner's King, Duchess of Oldenburg, Manx Codlin, Peasgood's Nonesuch, Sandringham, Ribston Pippin, Frogmore, Lane's Prince Albert, King of the Pippins, Lord Derby, Sturmer Pippin, Beauty of Kent, Bismarck, Newton Wonder, Ecklinville Seedling, Lord Grosvenor, Cox's Orange Pippin, and Tower of Glamis.

MISCELLANEOUS EXHIBITS.

Though miscellaneous exhibits are not particularly encouraged by the authorities at this show, they on the present occasion made a very fine and extremely diversified display. There were several splendid stands of flowers, as well as several of fruit, but we cannot give extended notice to them owing to so much of our space having been taken up by the competitive section.

Messrs. Paul & Son, the Old Nurseries, Cheshunt, had a large exhibit of pot Roses, baskets of Roses, and herbaceous plants, including Phloxes, as well as an assortment of Apples and Pears. Messrs. J. Laing & Sons, Forest Hill, staged an imposing and representative display of hardy flowers and Dahlias, the whole forming a very attractive exhibit. The Begonias also shown fully maintained the reputation of the firm. Messrs.

Harkness & Sons, Bedale, exhibited a very attractive display of Gladioli, Phloxes, Gaillardias, and a variety of hardy flowers. A grand exhibit of Roses came from Messrs. W. Paul & Son, Waltham Cross. They were chiefly Teas and Chinas. In the latter section Queen Mab was very noteworthy. A special feature was made by the varieties introduced by the firm during the Victorian era, which included Empress Alexandra of Russia, Sylph, Enchantress, Medea, and Corinna.

Messrs. Sutton & Sons, Reading, exhibited a choice collection of Tomatoes, including several novelties. Sunbeam, Perfection, Eclipse, and Prince of Wales were very fine indeed. Peachblow and Pomegranate, both novelties, were well shown, but the colour is hardly likely to meet the popular taste. Mr. B. Wells, Crawley, had an exhibit of Apples, including Peasgood's Nonesuch, Bramley's Seedling, Bismarck, and Worcester Pearmain. A pleasing change was provided by Mr. W. Wells, Redhill, who showed early Chrysanthemums, Harvest Home, Lady Fitzwygram, and Rose Wells being well represented. Mr. W. Horne, Cliffe, Rochester, staged a good collection of Apples.

From Mr. Owen Thomas, the Royal Gardens, Windsor, came a regal display of Pines, Grapes, Pears, Apples, and Tomatoes, all effectively arranged and affording a very pleasing exhibit. Messrs. H. Cannell and Sons, Swanley, had a group of Physalis Franchetti in good form, also a fine group of Cannas somewhat formally arranged. Messrs. J. Veitch and Sons, Ltd., had a very attractive show of Nerines grown in small pots, arranged with Palms and Maidenhair Ferns ; also a large exhibit of the leading varieties of Apples and Pears, with baskets of Physalis Franchetti and bunches of Rosa rugosa. The Horticultural College, Swanley, sent an exhibit of fruits both fresh and bottled, the latter consisting of Raspberries, Gooseberries, Currants, Plums, and Cherries.

Messrs. J. Cheal & Sons, Crawley, had an imposing display of Apples and Pears in dishes, also a number of cordons, to illustrate the free-bearing character of the varieties. The same firm showed Dahlias, including the Pompon, Cactus, and single sections. Messrs. Fisher, Son, and Sibray, Sheffield, staged a large collection of Apples and Pears, as also did Messrs. J. Peed & Sons, Norwood. Messrs. Gaymer & Sons, Attleboro', Norfolk, exhibited a collection of Apples and cider bottles, the latter for the most part empty, though some were filled with the necessary contents.

Messrs. A. W. Young & Co., Stevenage, had a display of ornamental Gourds and Tomatoes, also a large exhibit of hardy flowers. A very large and attractive collection of Apples and Pears was staged by Messrs. S. Spooner & Sons, Hounslow, comprising all the leading varieties. A collection of Pears and Grapes came from the Royal Horticultural Society's Gardens, Chiswick. This exhibit included the largest bunches of Grapes in the Show. The variety was Gros Guillaume from the large vinery at Chiswick.

A VISITOR'S COMMENTS.

ALTHOUGH there can be no doubt but that the Directors of the Crystal Palace may be assumed to know their own business best, yet their way of arranging the recent great fruit show did materially detract from the fine effect which otherwise would have been produced could the whole of the exhibits have been blocked into the centre transept, rather than broken into three sections, which not only detracted from the effect, but also materially from the pleasure such a fine show might be expected to furnish. Judging by the rather small attendance on the second day, it seems as if the firework attractions on the first day, when the attendance was large, were even greater with the public than the show. Somehow we never can at the Palace, grand a place as it is, get the crowds which went to see the famous Guildhall Fruit Show, but that was at least a gratuitous show, and was centrally situated.

I can hardly regard the Conferences on the two first days as successes. I could not attend the third. It seemed as if the public present at the Palace were not notified of the proceedings, either by means of prominent notices in the Palace or the distribution of small handbills. Unless these functions provoke more interest in the future they may not be worth keeping up. Probably they suffered somewhat from the fact that the papers read, though full of interest, were yet rather retrospective and descriptive than practical or controversial, but that was another of the products of a jubilee year that is happily nearing its end. Any future arrangements should require papers not exceeding twenty minutes duration on topics likely to arouse active interest and promote what is sometimes so lacking – free and full discussion. It would be well if, also, persons present would send in their names on paper if they wished to take part in the discussion, and that preference should be given to new men, or strangers, as in that way more widespread information is obtained. It is questionable whether the Conferences would not be better attended about 6 P.M., rather than in the afternoon, just after lunch, when everyone wants to enjoy the show.

No doubt from some quarters, especially from those who like to croak about the decadence of gardening, we shall hear that the Grapes were not up to the proper standard. Grape-showing seems to be like the exhibiting of other products, very much depends on the value of the prizes offered. Something also depends on the time of year when a show is held, and a good deal depends also on the duration of the show. Growers from a distance find that to bring fruit to the Crystal Palace means leaving home on the Wednesday, and getting back on Sunday or Monday. It is thus a long and a costly outing. Also the exposure of Grapes for three days takes the gilt off them very much. Such things make subjects for consideration, and big prizes are needed to encourage the bringing of the finest bunches. Yet all the same, there were many fine samples present, such as served to show that Grape-growing is far from being a lost art ; indeed, some of the best bunches shown would have been hard to beat anywhere. It is true size is a great point with so many persons, but Grapes have much higher qualities than is found in size of bunch, such as handsome massive contour, size of berry, finish, bloom, and flavour. These were features found in many directions at the Palace, and no doubt will be so long as the fruit show endures.

In very few cases were there disqualifications arising from non-observance of the classification of Apples, Pears, and Plums published in the schedule. That fact serves to show that these classifications were studied and observed. Their value is great, because they leave no room for dispute, should any arise, during the show. In Plums, one dish was disqualified because it was Monarch, shown as Kirke's. One wonders whether the exhibitor, after all, might not have been misled by receiving the wrong variety from the nursery. That there was any intention to do wrong no one believes. A prominent exhibitor was in one case, with fine fruit too, disqualified for showing Baumann's Red Reinette as a kitchen Apple, whereas it is now definitely classed by the R.H.S. as a dessert variety. As the classified lists run to seventy each of dessert and kitchen varieties, there is little need for making mistakes, the range of selection being so great.

Very interesting, as a rule, are the single dish classes, especially of Apples. Out of the twenty-three devoted to the dessert varieties, four only were poorly filled. The general entry in a class soon tells not only whether a variety is widely grown, but also whether it is good. The poorest represented were Allen's Everlasting, Egremont Russet, and Williams' Favourite ; indeed, these varieties are little known or grown. Surely there are many much more popular varieties than these worthy of all encouragement. I did not see in either anything specially worthy of notice, or showing that they were meriting the honour paid them. Rosemary Russet, Cockle's Pippin, Braddick's Nonpareil, Golden Pippin, Golden Russet, and Wyken Pippin are all better and well worthy of a place with the best. Few new dessert varieties can excel them, many are not nearly so good. There should be a variation of several varieties in the list every year.

Of kitchen varieties, there being no less than thirty-eight classes, a pretty comprehensive selection, a few seemed to be hardly worth the honour. There is Golden Spire for instance, a singularly ungainly Apple of the most wasteful description to grow, totally devoid of exhibition excellence, and one that rarely crops up in a good class selection. We have much better than that. Seaton House was indifferently seen ; and a very poor Apple, as its flesh is so very hard, though it is handsome to look at, is Spencer's Favourite or Queen Caroline. Such varieties as these, if anyone has decent samples, can always find their place in the class for any other variety. Hormead Pearmain might also be omitted, as it brings such poor competition. Far finer for ordinary use or for exhibition are Dutch or Catshead Codlins, Gloria Mundi, Waltham Abbey Seedling, and either of the Beefings, as really useful for keeping. I wonder how many grow St. Edmund Pippin, which two years, though I am not sure of in succession, took the first prize in the class for any other dessert variety. It has a brown russetty cover on a rather yellow skin, and makes a nice sample ; but it after all differs very little in appearance from Golden Russet, and I do not know in what respect it is better. If in this class judgment is to be for pure dessert purposes, the test should be flavour. I do not think any such test was applied at the recent show. I notice we have not seen the variety in the competition for Messrs. Veitch & Sons' flavour prizes yet.

Some useful information might be obtained were a census of the best twelve dessert or kitchen Apples and twelve best Pears in every case for succession, for cropping, and general excellence, either at the show or taken from the Society's single dish classes. We have not yet, so far as I know, obtained any general opinion on these things since the Chiswick Apple and Pear Congresses.—A. D.

ISLE OF WIGHT HORTICULTURAL ASSOCIATION.—The monthly meeting of the above Association was held at Newport on Saturday last. Dr. J. Groves, J.P., presided over a large attendance of members. A paper was read on "Fruit Culture in the Isle of Wight," by Mr. S. Heaton, Hon. Sec. of the Association, and Horticultural Instructor for the Isle of Wight County Council. There were excellent collections of fruit staged by Messrs. G. Bunyard, Maidstone ; T. Collister, Bembridge ; C. H. Snork, Shanklin ; A. J. Munson, Brading ; Geo. Williams, Gatcombe ; W. Cooke, Wootton ; R. Parsons, W. Scott, C. Orchard, H. Webber, C. Russell, J. J. Limington, Newport; T. E. Mole, Chillerton ; and the Rev. H. R. Venn, Newtown. Mr. J. H. King, Blackwater, staged bottled fruits of Currants, Gooseberries, and Plums ; Messrs. F. Guy and T. E. Mole, Tomatoes ; and Mr. J. Niblett, Niton, Peas, Cauliflowers, and Cactus Dahlias. Mr. W. Matthews, Carisbrooke' showed Apples and blooms of Dahlias ; Mr. H. Webber, a collection of Carnation Margaret, and Mr. Martin Silsbury, Shanklin, seedling blooms of Chrysanthemums. The Adjudication Committee awarded several of the Association certificates for the meritorious exhibits, and named a large number of dishes of fruit which had been staged for that purpose. A vote of condolence was passed with Mrs. Spittal and family in their sad bereavement in the loss of the Rev. J. Spittal, late Vicar of Haven Street, who was an honorary member of the Association from its commencement, and a prominent rosarian and horticulturist. Thirty new members were elected, which brings the total number of members up to 213. The next lecture will be on "Chrysanthemums," by Mr. J. Barkham, of Haven Street.

Notes & Gleanings

EDITORIAL NOTICE.—It is particularly desired that all communications, parcels, catalogues, and newspapers intended for the EDITOR, be sent direct to 8, ROSE HILL ROAD, WANDSWORTH, S.W.

EVENTS OF THE WEEK.—London horticulturists will have a busy day on Tuesday, the 12th inst., that is to say if they attend each of the three events that are fixed for that date. The Committees of the Royal Horticultural Society will meet at the Drill Hall, James Street, Westminster. The second show of the National Chrysanthemum Society will open on that day and continue over Wednesday and Thursday; while in the evening of Tuesday the United Horticultural Benefit and Provident Society will hold its annual dinner at the Holborn Restaurant under the presidency of Mr. H. B. May.

—— WEATHER IN LONDON.—On the evening of Wednesday, the 29th ult., a terrific thunderstorm passed over London, being more severe in the northern suburbs. Much damage was done, and the rain fell in torrents. Thursday, Friday, and Saturday were fine, but heavy rain fell during the early hours of Sunday morning, the day, however, proving dry though dull. Several drizzling showers came at intervals on Monday, while on Tuesday it was fine, and Wednesday opened foggy.

—— WHO SPLICED THE GRAPES AT THE CRYSTAL PALACE?—I am quite sure that all readers of the Journal who are interested in the above will feel indebted to "A. D." (page 312) for the explanation given on behalf of the unfortunate exhibitor as to how and why the bunches of Grapes had been tampered with. What a rough and ready young assistant! for in a previous issue of the Journal (page 196) I notice "On-looker" states that each bunch had been spliced to the tune of one, two, and three pieces. I cannot help thinking that the assistant, though clumsy, must nevertheless be rather smart to be able to put together broken limbs so successfully. Surely he would do well in another profession.—OBSERVER.

—— A FINE ONION BED.—One of the finest beds of Onions I have seen this season was in the gardens of Lockinge Park. Several varieties, such as Ailsa Craig, Lord Keeper, and others, were growing side by side, and a more even bed could not be desired. All the bulbs of Ailsa Craig ranged about the same size, as did those of the other variety named. It was apparent that the soil had been excellently prepared, while the after attention also must have been of the closest. Over the bed was spread a light mulching of half-decayed horse droppings, and it cannot be doubted that the bulbs have received a considerable amount of benefit therefrom. The bulbs, when I saw them, were ripening off beautifully, and no difficulty would have been experienced in securing three or four dozen bulbs fit for the show table of either of the varieties. This bed, like the rest of the vegetable garden, is a credit to Lord Wantage's diligent gardener, Mr. W. Fyfe.—VISITOR.

—— EMIGRANTS' INFORMATION OFFICE.—The October Circulars of the Emigrants' Information Office and the annual penny Handbooks show the present prospects of emigration. There is no demand for anyone in Canada at this season of the year. There is no demand for more labour in New South Wales. The drought has been terribly severe in nearly all parts, except those watered by the coastal rains; the Riverina district has perhaps suffered worst of all. Though there has been a more general fall of rain recently, the heavy losses of stock, and the consequent decrease in the output of wool, must seriously affect for some time the demand for labour. The drought in Victoria also has been exceptionally severe, and there is no demand for more labour. The carrying on of the Mildura Irrigation Colony is now practically assured, and the Government will bring in a Bill to authorise a guarantee of money for five years. In all the farming districts of Queensland a good demand exists for competent ploughmen and farm labourers. In Western Australia the demand for mechanics, farm and general labourers, miners, and female domestic servants continues. In Tasmania there is no actual demand for labour. During the next few months there will be a demand in New Zealand for good men accustomed to all kinds of farm labour. Further information may be had from the Emigrants' Information Office, 31, Broadway, Westminster, S.W.

—— GARDENING APPOINTMENT.—Mr. W. Simmons, gardener for the late K. R. Murchison, Esq., Brockhurst, East Grinstead, Sussex, has been appointed gardener to C. Page, Esq., Woodside, Burstow, near Horley, Surrey.

—— ASTERS AT MORTLAKE.—Travellers on the South-Western Railway, between Mortlake and Richmond, will doubtless have noticed the large beds of Asters on the nursery ground by the line side. This was an extensive trial, that has been conducted by Messrs. Jas. Carter & Co., High Holborn, and some beautiful colours could readily be perceived. The recent rain storms have, however, played havoc with the blooms, whose beauty has now departed.

—— POISONOUS PROPERTIES OF DAVALLIAS.—In reply to your correspondent, "Journeyman," page 313, respecting the poisonous properties of Davallia fijiensis, I may mention that several varieties of that beautiful Fern possess the peculiarity of which he speaks. D. Mooreana is far the worst variety I have had experience with. We have a large plant in our collection; each time we have occasion to move we experience an unpleasant sensation, similar to that described by "Journeyman." In my case the acute smarting is accompanied with itching and sneezing. The young men are affected in much the same way. We attribute it to the spores, which, being released from their cases through the shaking of the fronds, settle upon the skin and cause the irritation.—T. L.

—— KEI APPLE AS A HEDGE PLANT.—I was pleased to read the paragraph referring to the Kei Apple on page 266. There are certain good points which make one wish for a better acquaintance with this evidently useful hedge plant. The fact that it is an evergreen will recommend it to many; again, its 6-inch thorns are suggestive of its being much preferred to Thorns for field hedges. Have any of your readers any experience of this plant in Great Britain? I should much like to give it a trial, but am at a loss to know where to look for a supply.—T. D. S. [The paragraph was taken from one of the excellent Bulletins that are issued by the Kew authorities. Perhaps if you wrote to the Director, Royal Gardens, Kew, he would be able to assist you with information.]

—— DAHLIAS AT KINGSTON.—Through the kindness of Mr. S. Mortimer of Farnham, who is undoubtedly now one of the champion Dahlia growers and exhibitors, I was enabled on Saturday evening last, on the occasion of giving the first of our fourteenth session of Winter Saturday Popular Entertainments in Kingston, to show the people a really splendid display of Dahlias, such as had never before been seen in the town. The spectators literally opened their eyes in astonishment at the wonderful size and form of the Shows, the beauty of the Pompons, and the singularly lovely Cactuses. The group was 30 feet long, and comprised some 170 Show varieties, and about 30 of Cactuses and Pompons, backing the boxes. Whilst the Shows included every good class variety, the Cactuses comprised A. Deal, the new scarlet; Starfish, Cycle, Lady Penzance, Miss A. Nightingale, J. A. Frewer, Harry Stredwick, Harmony, and others; and the Pompons included Winifred, E. J. Trucker, Gipsy, Vivid, Arthur West, Lady Blanche, Tommy Keith, and Little Julia. Announcement of the Dahlia display helped to cram the Great Hall of St. James to its very utmost, scores being unable to obtain admission. Kingston district has no summer flower show, and many beautiful popular flowers are here in consequence seldom seen. —A. D.

—— DEVON AND EXETER GARDENERS' ASSOCIATION.—The annual meeting of this Association was held last week in the Council-room of the Guildhall, Exeter, under the chairmanship of the President, Mr. E. A. Sanders, J.P. There was a numerous attendance, including the Right Worshipful the Mayor of Exeter (Mr. Alderman R. Pople), Mr. P. C. M. Veitch, J.P., and others. After the adoption of the report Mr. Sanders was re-elected President, Mr. Andrew Hope Secretary, and Mr. W. Mackay Hon. Treasurer. The following Committee of Management was also elected, on the motion of Mr. R. J. Mills, seconded by Mr. G. Anning:—Messrs. J. Abrams, W. Andrews, J. Baker, W. R. Baker, W. Charley, G. C. Crabbe, J. Lacon, J. Luxton, J. Rogers, W. Rowland, S. Radley, and J. Weeks. All the elections were unanimous. Mr. P. C. M. Veitch said he felt sure all the members present would like to thank the Mayor for the encouragement he had given the Association during the time he had held that office, and for his kindness in granting them the use of the Guildhall for their assembly. Mr. G. B. Carlile seconded the vote of thanks, which was carried unanimously. The Mayor observed that it gave him a great deal of pleasure to grant the loan of the Guildhall, and he had taken upon himself to grant them the use of it for another year.

—— The Royal Horticultural Society. — We are informed that Mr. J. Weathers has resigned his position as Assistant Secretary to the Society. He was appointed to the post about eight years ago.

—— Russellia juncea.—Though not one of the showiest of our greenhouse plants, this is certainly worthy of a place in every collection. It is specially serviceable where hanging plants are required, and owing to its pendulous habit it can only be shown to advantage in this way. The flowers, which are trumpet-shaped, about 1 inch long, and of a brilliant scarlet colour, are freely produced nearly all the year through. The numerous long, rush-like, branching stems are clothed with small linear or lanceolate leaves. It is a plant of comparatively easy culture; it can be grown either in pots or baskets, and delights in a light, moderately enriched soil. A house, where a night temperature of 55° to 60° is maintained during the winter months, will suit this plant well. The most convenient method of propagation is, says a writer in the "Garden and Forest," by cuttings made from the little branchlets taken off with a heel. These root readily in sand or sandy soil in a propagating case with gentle bottom heat.

—— New Recreation Ground for Richmond.—We hear that the negotiations between the Town Council and the Crown authorities for the purchase of a large portion of the famous Old Deer Park as a public recreation ground are almost completed, and the hope is expressed that the "new lung for Greater London" will be ready for public opening on the 10th October. The Town Council will acquire nearly 90 acres of the park, and a deputation from the Council will this week wait upon the Chief Commissioner of Works in order to settle the final agreement. The new ground will meet a long-felt want of the local cricket and football clubs, in addition to affording one of the most picturesque open spaces on the banks of the Thames. During the week a meeting of the representatives of the local athletic clubs will be held for the purpose of forming a ground committee to assist the Town Council in regulating the park, and it is hoped it will be possible to secure a member of the Royal Family to perform the opening ceremony.—("Garden.")

—— Dahlias at Rothesay.—Messrs. Dobbie & Co. of Rothesay have this season at their famous nurseries 3 acres of Dahlias, with 15,000 plants in magnificent bloom. Every autumn I am becoming more enamoured of the Dahlia. Though it has not the fragrance of the Lily, the Carnation, or the Rose, for floral impressiveness, when planted with a view to artistic effect, its qualifications are supreme. I like it even better than the early flowering Chrysanthemum, and that is saying much. In my own garden the only varieties of the Dahlia much cultivated are the Single and the Single Cactus, which do not attract earwigs quite so much as their stouter sisters; and while they have also a much more graceful and refined appearance, are considerably less disturbed by the somewhat trying visitations of the equinoctial blasts, which generally make havoc of our gardens unless very strongly sheltered, at this period of the year. It is very unfortunate for these and other fine autumnal flowers, such as the Hollyhock, the Speciosum Lily, and the early Chrysanthemum, that they should, just when they reach the culmination of their beauty, be treated by Nature so very unmercifully.—David R. Williamson.

—— Potato Crop.—This year the crop of Potatoes in Great Britain has had devoted to it 352,365 acres in England, 32,609 acres in Wales, and 119,940 acres in Scotland, the total for Great Britain being 504,914 acres, consequently England possesses 69·8 per cent. of the tuber area, Wales 6·5 per cent., and Scotland 23·7 per cent. The total decrease on the year amounts to 58,827 acres, consisting of 47,739 acres in England, 1239 acres in Wales, and 9849 acres in Scotland. Each of the English counties participated in the diminution except Devon and Rutland, which gained 100 and 11 acres respectively. The decline in Lincoln is 7641 acres, which more than balances the increase of 5754 acres in that county in the preceding year. Other noteworthy declines, according to a contemporary, are those of 3448 acres in the West Riding of Yorkshire, 3179 acres in Essex, 2951 acres in Kent, 2533 acres in Lancaster, 2505 acres in Cambridge, 2295 acres in Bedford, and 2180 acres in Chester. The largest county areas under Potatoes in England are 50,197 acres in Lincoln, 37,053 acres in Lancaster, 23,252 acres in Chester, 23,152 acres in the West Riding, and 19,847 acres in Cambridge. The area under Potatoes shows a decline in all the counties of Wales except Montgomery and Radnor, in which the increases are 60 acres and 2 acres respectively. The largest county area under Potatoes in Wales is 5936 acres in Cardigan. Except Nairn, which has the small increase of 11 acres, all the Scottish counties show decreases. The highest county areas of Potatoes are 13,326 acres in Fife, 11,429 acres in Forfar, 11,416 acres in Perth, and 7343 in Ross and Cromarty.

—— Sussex Rainfall in September.—The total rainfall for the past month at Haywards Heath was 2·82 inches, being 0·31 inch below the average. The heaviest fall was 0·54 inch on the 5th. Rain fell on thirteen days. Total for the nine months 23·23 inches, 2·96 above the average. The maximum temperature was 71° on the 29th, the minimum 36° on the 19th. Mean maximum, 64·15°; mean minimum, 47·03°; mean temperature, 55·59°, a little above the average.—R. I.

—— September Weather at Driffield.—Mean temperature at 9 A.M. (corrected) 54·74°. Wet bulb 52·42°. Mean maximum 60·57°; mean minimum 45·08°. Highest, 66·8° on the 24th; lowest, 36·6° on the 12th. Mean of maxima and minima 52·82°. Mean radiation temperature on the grass 41·22°; lowest, 30·5 on the 4th. Rainfall 2·780 inches. Number of rainy days, fifteen. Greatest amount on one day, 0·710 on the 1st.—W. E. Lovell, *Observer, York Road, Driffield.*

—— September Weather at Hodsock Priory.—Mean temperature, 53·5°. Maximum in the screen, 67·9° on the 13th; minimum in the screen, 34·5° on the 19th; minimum on the grass, 26° on the 19th. Frosts in the shade, 0; on the grass, 10. Sunshine, 115 hours, or 31 per cent. of possible duration. Rainfall, 2·02 inches. Rain fell on twelve days. Maximum fall, 0·47 inches on the 1st. Rainfall from January is 17·54 inches. Difference from average – 0·77. A cool but otherwise normal month. After some rain on the first few days dry weather set in.—J. Mallender, *Worksop.*

—— South Wales Weather.—The following is a summary of the weather here for the past month:—Mean maximum temperature, 66°. Highest reading, 85° on the 12th; mean minimum, 40·4°; minimum 29° on the 9th. Total rainfall, 5·79 inches. Greatest fall, 1·27 inch on the 29th. Rain fell on eighteen days. There were six sunless days. The wind was in the S.W. and W. on eleven days, and in the N.W. on eight days. The last sixteen days of August and the first five days of September rain fell every day, making a total for the twenty-one days of 7·43 inches. The early part of the month the wind was very strong, but for the latter part the wind was quiet. Total rainfall up to date, 41·61 inches, which has fallen on 164 days.—Wm. Mabbott, *Dowlais.*

—— The Weather Last Month.—September gave us a period of nine fine days in succession—5th–14th. The remainder of the month was wet. No frost occurred during the month. The wind was in a westerly direction twenty days. Total rainfall amounted to 2·13 inches, which is 0·19 inch below the average for the month. This fell on nineteen days, the greatest daily fall being 0·48 inch on the 5th. Barometer (corrected and reduced) highest reading 30·533 inches on the 13th at 9 P.M.; lowest, 29·273 inches on the 1st at 9 P.M. Thermometers—Highest in the shade 67° on the 26th; lowest, 34° on the 10th. Mean of daily maxima, 61·30°; mean of daily minima, 45·10°. Mean temperature of the month, 53·20°; lowest on the grass, 30° on the 10th; highest in sun, 127° on the 9th and 11th. Mean of the earth at 3 feet, 55·96°. Total sunshine, 135 hrs. 35 mins. There were three sunless days.—W. H. Divers, *Belvoir Castle Gardens, Grantham.*

—— Coal Ashes for Mulching Fruit.—An exchange says that coal ashes from both hard and soft coal have been tried as a mulch for Gooseberries and Currants with excellent results. We have used them around Peach and Pear trees, and thought it a considerable benefit to the fruit and the tree, retaining moisture as well as adding to the fertility. But, says an American contemporary, we selected the ashes made in summer, when about as much wood was burned as coal, the latter being used during the times when there was washing, ironing, or baking to be done, and only wood used for preparing the light meals of the day. Perhaps that was better than the ashes made in winter, when no wood was used, as the fires did not go out for weeks at a time.

—— Darlington Park.—Mr. Morrison, the Darlington Park Superintendent, has been the recipient of a gratifying communication from her Majesty the Queen in connection with the commemorative devices which have formed such an attractive feature of the Darlington Park during the Jubilee year. It will be remembered, says the "Northern Echo," that Mr. Morrison, whose devices in carpet bedding have earned for him a more than local notoriety, determined this year—the sixtieth of her Majesty's remarkable reign—to surpass his former efforts, and in this he succeeded in a remarkable degree. The central device is a large representation of the Royal arms of England, with the proper heraldic colouring, and on either side are medallion portraits of her Majesty, one as a young girl of eighteen, with the date "1837" below; and the other representing her at the present time, with the date "1897."

CAMASSIA ESCULENTA.

CAMASSIA ESCULENTA (fig. 52) is not a very widely known plant, but it has some claims to recognition which it may be well to advance. In the first place, when it has pushed up several stout stems surmounted by racemes of bright blue flowers in summer it is an object which most persons admire, and in the second place it is no delicate or tender plant, requiring careful nurture to bring it to perfection, but it is vigorous, hardy, and accommodating. To these recommendations it may be added that the bulbs are cheap and very easily grown. We first made the acquaintance of this plant in the garden of a great flower lover, an amateur whose love of gardening had concentrated itself in an intense passion for hardy flowers. He thought very highly of it, finding it not only extremely decorative in the garden but of considerable value for cutting. We also admired it greatly, and returned thanks for the promise of a few bulbs in the autumn, but which promise was not kept. They are to be bought from the majority of seedsmen in autumn, and could no doubt be had now from most advertisers of bulbs. They should be planted at once towards the middle of the border, as they grow about 18 inches high, well working the soil previous to inserting them, and covering them 2 inches deep. They may also be grown in pots, placing them half an inch below the surface, employing rich porous soil, and plunging in cocoa-nut fibre refuse for a few weeks prior to placing in the greenhouse. On looking up the habitat of Camassia esculenta we find it is a native of North America, and the bulbs are said to be eaten by the Indians, hence, presumably, its specific name. The tastes of the Red Man are not, however, such as we care to copy, and we can very well content ourselves with growing the Camassia for the sake of its flowers, which, as the engraving will indicate, are extremely attractive.

NOTES ON BULBS.

HYACINTHS.

WHEN the last instalment of these notes came to a conclusion on page 288, we had brought the bulbs to that stage where feeding was commenced as they advanced to the flowering stage, and we would now take up the line from there. Opinions vary very considerably on the question of staking, which is in almost all cases an absolute necessity, for the spikes when well grown are too top-heavy to stand in an upright position. Some growers use pieces of stout wire cut to the desired length, but for my own part I prefer neat wooden stakes, either green or white. Whether painted or not, it is obvious that they must be put as closely to the spike as possible, or they will become unsightly. To obviate this the sticks should be very sharp-pointed, when they may be forced into the bulb itself and will not do it any material injury, provided they are not pushed in too far. For tying, of course the thinnest pieces of raffia ought to be used, and these can with patience be so hidden by the bells as to be absolutely imperceptible. If the plants are to be exhibited their good appearance is enhanced by placing the pot containing the bulb within a larger one, surrounding it with damp moss and surfacing the whole with natural furnishing moss. This acts admirably as a foil for the flowers, and the colour effect is considerably heightened.

Let us now pass for a moment to the varieties, of which there are scores of all colours amongst the singles, and lesser numbers though still plenty for selection of the doubles. Some growers go in for the greatest possible number of distinct, or so-called distinct, varieties, but this has never been my practice, as I am strongly of the opinion that with a reasonably limited selection the best results can be achieved. I have one or two prime favourites of red, white, blue, and yellow, and of these I grow several bulbs, while of others not so popular the stock is restricted to two or three of each, these being desirable for the sake of change. For example, of La Grandesse we always have two or three dozen and the same of La Franchise, and thus insure a number of pure and tinted whites of the first quality. Similarly Grand Maître and King of the Blues receive good attention amongst the blues, while reds are represented by the charming Von Schiller and the brilliant Vuurbaak. As the yellows of the best quality are much scarcer the only one grown in quantity is Ida, which if older than many is certainly one of the most useful. Doubles we are not very much entranced with, as the majority of them produce spikes that are somewhat loose, but below will be found a brief selection of the best that we have tried of this section. As few growers will confine themselves to half a dozen varieties we purpose now naming several others that can be recommended strongly for their excellent properties, if sound bulbs are procured from a reliable source.

Giving precedence to the blues as being alphabetically first on the list, we shall find abundance of material from which to choose. Let us not omit to insert here Grand Maître and King of the Blues, to which we will add ten to give a dozen, as this will be more than enough for the majority of people. Czar Peter, usually described as porcelain blue, is a first-rate variety, as is Grand Lilas, which can go as a companion to King of the Blues, this latter being Oxford and the former Cambridge blue. For a rich purple we have not found one superior to Souvenir de J. H. Veen, though several have been more recently introduced. King of the Blacks needs no descriptive word. Blondin is old, but undoubtedly good, its greyish blue flowers with their silvery sheen being very beautiful. The white-edged bright blue bells of Lord Palmerston are always admired, as are the handsome light blue spikes of Leonidas. The veteran William the First is still worthy of inclusion amongst the dark, as is the equally aged Charles Dickens, which is blue shaded with purple. This bring us to eleven, and as a twelfth we will add Lord Derby, which when seen in good form is quite equal to any of the foregoing.

In making a selection of a similar number of reds we would add to the two already named Queen of Hyacinths, carmine in colour and very pretty; Belle Quirine, bright rose with lighter stripes; Cavaignac, a soft pleasing salmon; and Countess of Rosebery, dark red, to make the first half dozen. Then we would follow with King of the Belgians. This is a very good variety, the colour being bright red and the bells well set on the spike. The large trusses of Fabiola would be missed if omitted, as would the delicate pink-hued flowers of Gigantea, which is one of the closest in the truss that we have grown. Linnæus, deep carmine, and Macaulay, carmine striped, are both worthy of inclusion, while to exclude Diebitz Sabalkansky, scarlet, would be an error.

There can be no necessity to grow as many as a dozen varieties of white varieties, so the number named will be restricted to eight, and we will make up the dozen with four yellows. Madame Van der Hoop, though really a pure white, shows traces of a slight tint occasionally; but this rather adds to than detracts from its beauty. Another, with large bells, is Mont Blanc, and the same may be said of Alba Maxima. Very charming too are Grandeur à Merveille and Leviathan, which are both blush in colour, and these, with Alba superbissima, and the two already noted, will give us our selection of eight. Of yellows we should add to Ida, Bird of Paradise, King of Holland, and La Pluie d'Or, each of which is very good in its way. The violet and mauve varieties we do not touch, as they are not popular in our establishment, and mention has only been made of those of which we have had personal experience.

Our collection of doubles is always limited to one dozen varieties, allotted in the following manner:—Four each red and white, three blue, and one yellow; and though we do not grow exactly the same each year, the best results have been achieved with the undermentioned. Still giving the blues the premier place, we commend to all Laurens Koster, rich purple; Blocksberg, light blue; and Charles Dickens, blue with a shade of purple, as forming a good trio. First of the whites must be La Tour d'Auvergne, which is early and excellent for forcing, while to it we would add Princess Alice, Bouquet Royal, and Lord Anson, the first two being pure white, and the latter pair tinted. Of reds we always grow Koh-i-Noor, and usually Noble par Mérite. For two others try Grootvorst, blush, and Louis Napoleon, bright red. The double yellow with which we have had the most persistent success is Jaune Supreme. With these the list may be closed, and we think that well-grown plants will be certain to give satisfaction. It will be observed that no very expensive varieties are included; this is because our annual allowance for bulbs will not permit of the purchase of those which cost 2s. or 3s. apiece. Like many others, we have to cut according to our cloth.

In the issue of the *Journal of Horticulture* for August 19th, page 171, there appeared over the initial of "S." an excellent article on the culture of Roman Hyacinths, so that it will be superfluous for us to give details here. Suffice it to say the treatment there recommended has been proved to be in all its details good. Our earliest Romans are making good growths, but it is not until Christmas and the New Year that we experience any particular demand for them, though they are much appreciated earlier.—H. ROSE.

(To be continued.)

THE PLEASURES OF FRUIT GROWING.

(*Concluded from page* 306.)

THE other example is of a different character, but not less interesting. A farmer determined to test for himself the possibilities of hardy fruit culture, and commenced the investigation cautiously but judiciously. He had experienced the difficulties of ordinary farming, and possessing the freehold of some 20 acres of land, he thought that planting a portion of this with fruit would furnish him with change and recreation, while it might yield his family some return in after years. The result has been that in about a dozen years he relinquished his original occupation, and now devotes himself entirely to fruit growing, with manifest satisfaction to himself from every point of view. The employment was a pleasurable study to him at first, and it now combines both pleasure and profit, the latter in a degree that had not been anticipated.

The soil is heavy and difficult to work, but fertile, and the situation is well elevated, and for this reason escapes the spring frosts experienced in low-lying districts. Planting was commenced with standard Apple and Pear trees, but these have given the least satisfaction up to the present time, though a few are now beginning to yield

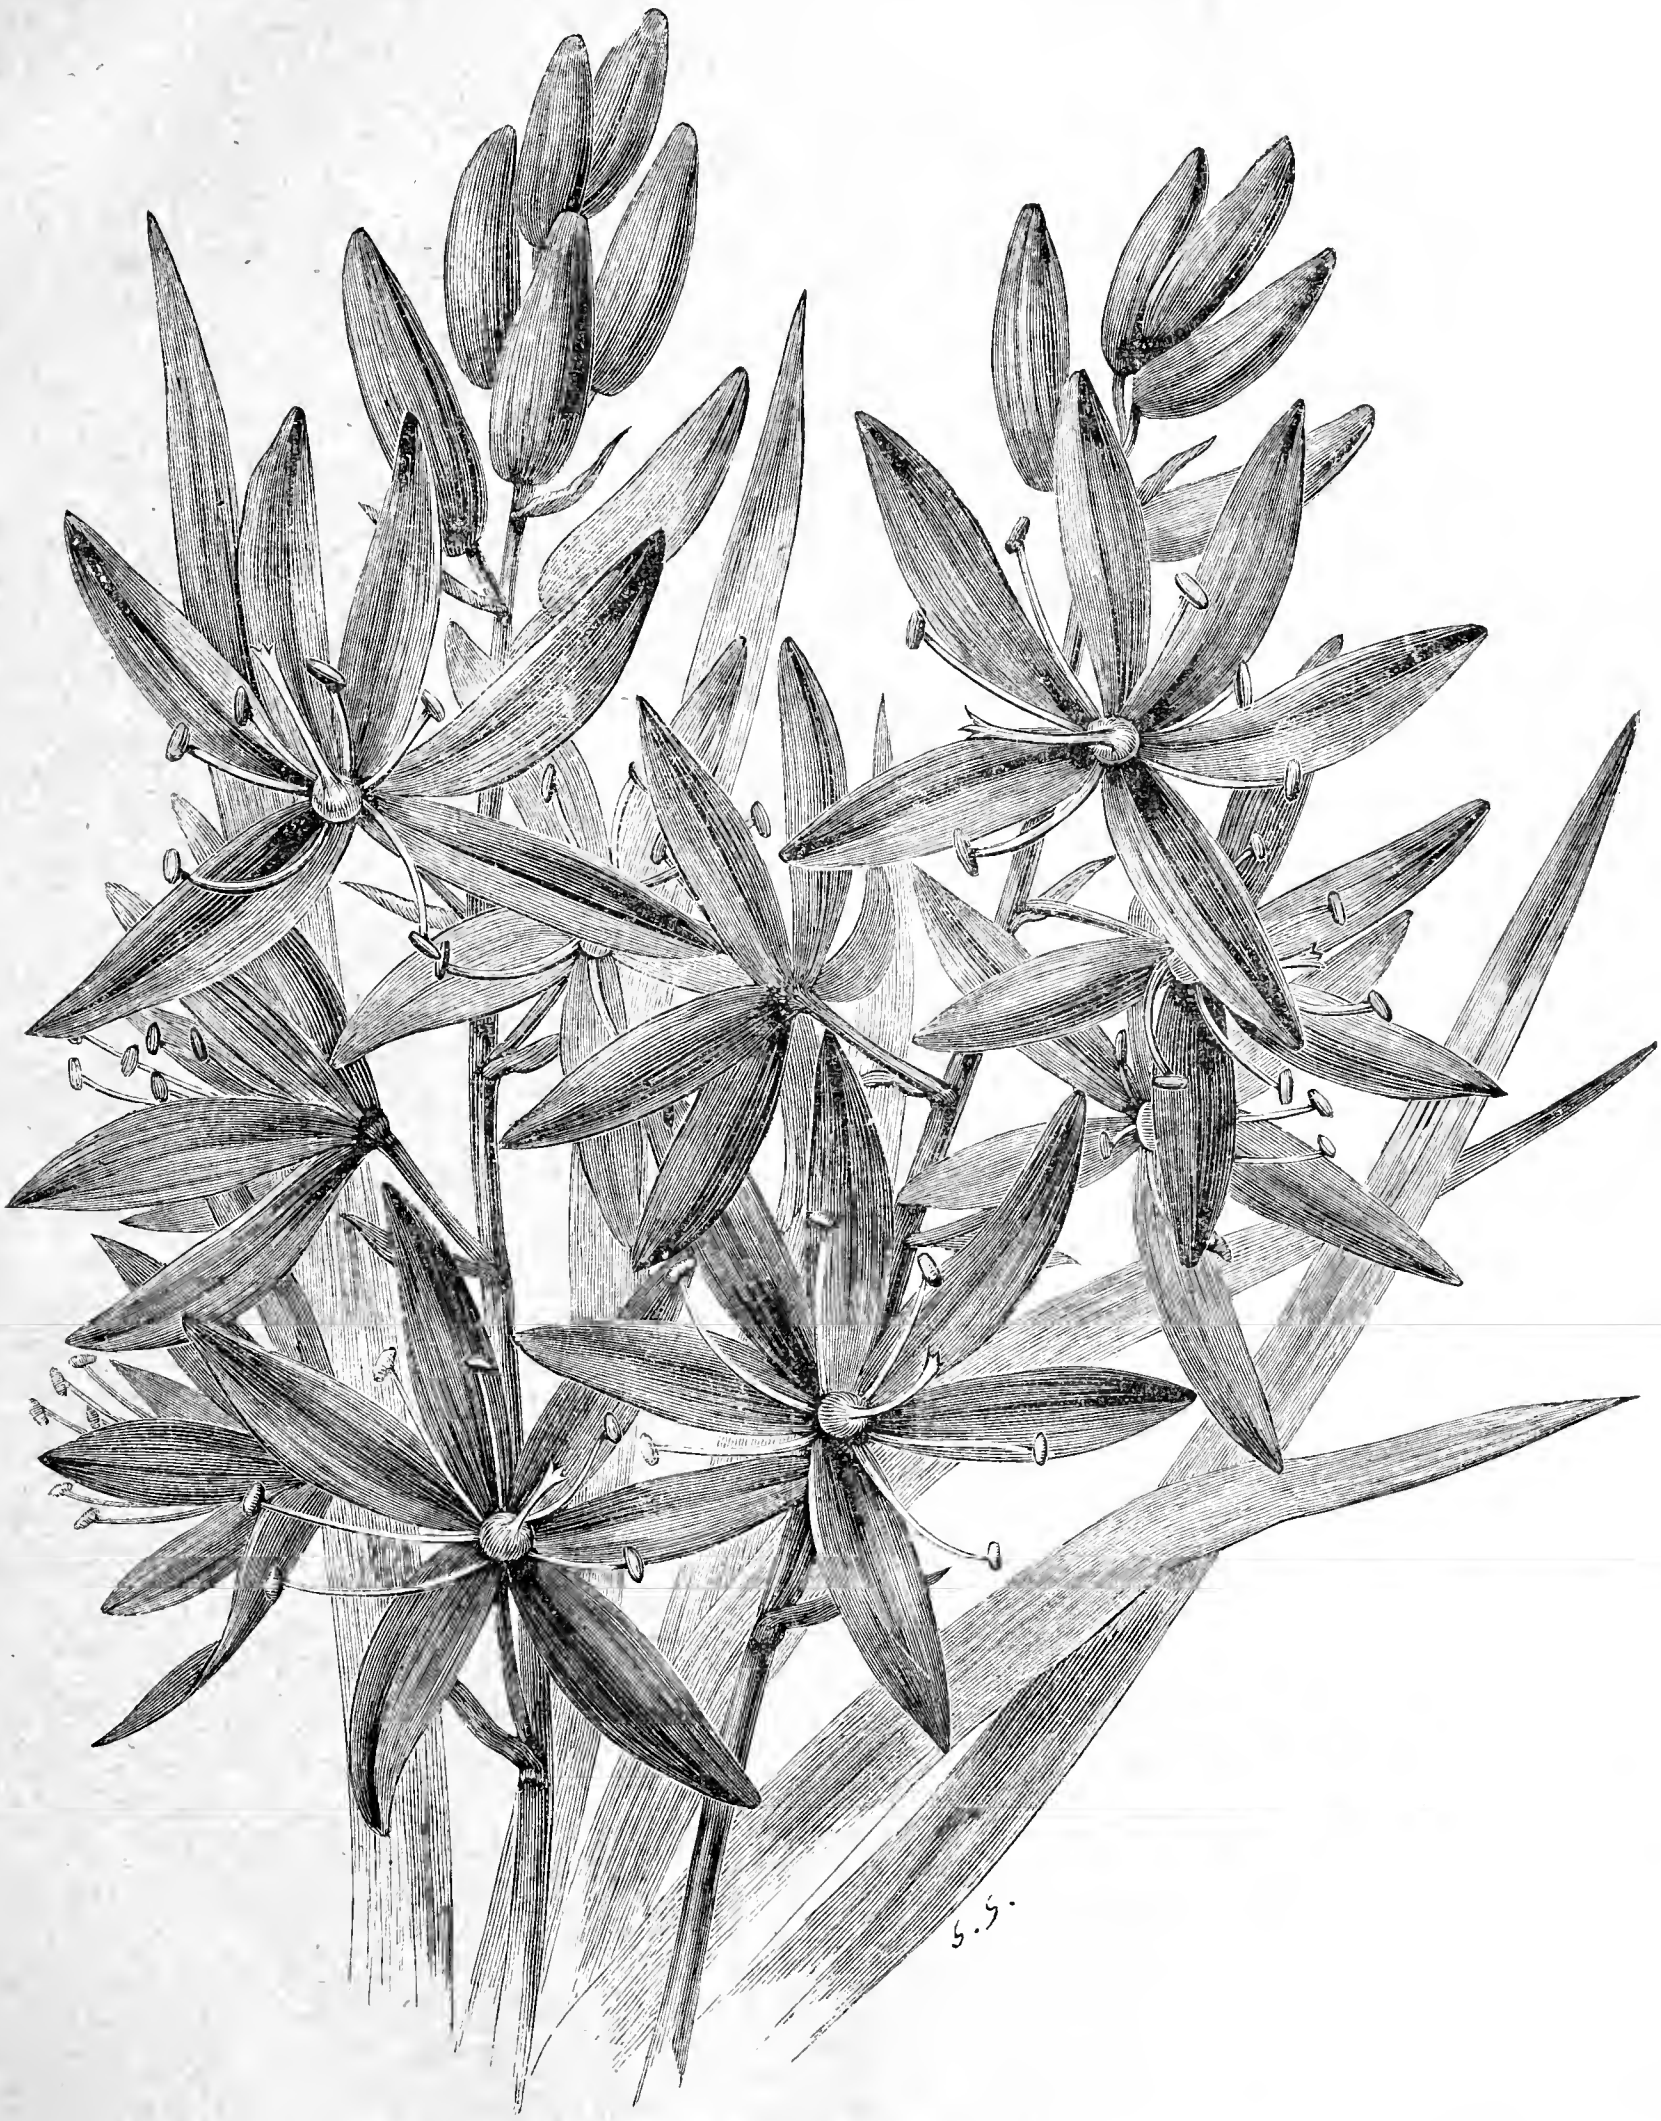

FIG. 52.—CAMASSIA ESCULENTA.

something like profitable crops. Dwarf Apples and Pears, with half-standard or bush Plums, have afforded by far the best returns, and the majority are now in excellent condition, yielding in fair seasons bountiful crops of clean well-developed fruits. For several years the owner regarded his fruit plantation as a hobby pure and simple, and in consequence indulged in many experiments, that would perhaps not have been otherwise undertaken. Yet to a man of close observation, a real student of Nature, these have yielded considerable interest, and proved of practical value also.

The result of some twelve years' experience may be summed up in a few words, and though all his conclusions may not be in accordance with the opinions of others, he has certainly had ample justification for them in his own practice.

First, as to the age of the trees to be planted, Mr. A. (as we may call him) is emphatically of the opinion that, allowing for the difference

in cost, maiden trees will give as good results in five years from the date of planting as will three-year-old trees. This in itself is an important subject, and requires careful consideration where a large area of land is to be planted. I have tried trees at different ages, and must confess to a decided preference for those three years of age, which have been subjected to careful preparation in a nursery until that time. These, when carefully planted and tended, are soon established, and a crop may be had in the second year, the chief point being to prevent free-cropping varieties bearing heavily enough to interfere with their after progress. Mr. A. contends, however, that the two years in the ground undisturbed, which brings the trees to the same age as the three-year-olds, is all in their favour as fruit bearers, and they are consequently able to bear larger crops and greater strain with safety. The subject is a wide one, and conclusions must be modified to some extent by differences of soil, situation, and varieties, but the bearing upon the prime cost of planting orchards is so great that it is worthy of close attention. Mr. A. has certainly succeeded with his maiden trees, and I do not question his results; but a careful comparison under similar conditions is needed to convince me that planting maiden trees is the most profitable, for my experience tends in an opposite direction, though if the question of decreasing the first outlay is the only consideration, the younger trees have the advantage.

Another point is in regard to planting, and here Mr. A. has formed a strong opinion founded on his own experience. He advocates and practises planting trees upon a firm base where the soil is heavy, not disturbing the soil below or digging holes, but simply heaping the soil over the roots and adding to this with weathered soil every year. Much can be said in favour of this treatment under similar conditions, for there is no doubt that digging holes in heavy clayey soil and planting in these is often productive of the worst results. In another respect it is contended that planting on the surface is beneficial; for example, it forces the roots to spread in a horizontal direction, and Mr. A. believes—and he points to many trees in proof of his observations—that this induces a corresponding spreading habit of growth in the branches, thus helping to keep the trees open and free from crowding.

Still a third matter demands notice respecting Mr. A.'s practice, and that is with regard to pruning. He maintains that young trees are cut far too often and too hard, and in many cases beyond the first shaping and subsequent thinning, or the removal of crossing branches, his trees have been free from the knife for some years. He directs attention in many cases to the fruit buds and spurs studding the lower parts of the branches and gradually extending upwards year by year, and contrasts these with others where continued pruning has resulted in increased but sterile growth.

In the matter of manures opinions have also been formed at variance with some accepted notions, but they are worthy of record because they have been proved by experience, in this case at least. Heavy soils are generally regarded as possessing abundance of potash, and theoretically it is unnecessary and wasteful to supply this as manure, yet on his heavy soil Mr. A. has found for many years that nothing gives such a good result as potash. Nitrogen in various forms he has tried and discarded for some time, and now relies exclusively upon superphosphate and potash in the proportion of 2 cwt. of the former to 1 cwt. of the latter, supplied as kainit. In the production of healthy but fruit-bearing growth this system of manuring has given the greatest satisfaction; no stable or farmyard manure is now employed, and only in a few instances of exceptional weakness has either sulphate of ammonia or nitrate of soda been used.

Such, in brief, are a few of the subjects of investigation which have yielded Mr. A. much pleasure in past years, and at the present time he has the satisfaction of reaping the results of his work in a more substantial way. At a future time something farther may be said in regard to this plantation, for it is full of interest in connection with the behaviour of certain varieties.—Observer.

DECORATIVE WORK.

(*Continued from page* 308.)

This paper, as premised in our last, pertains to what may be considered, from a gardener's point of view, the most important, as it is in various details the most comprehensive, phase of our subject—viz., the decoration of a private mansion upon some festive occasion. The decorator having received timely notice, and possibly some general outlines, which may be little more than the particular use to which certain reception or other rooms will be devoted to, will at once, even if months prior to the event, commence preparations in every available way. As no two houses are alike, no two men are alike in their methods, and season and circumstances vary considerably, it will, for our purpose, be sufficient to give one illustration which, though drawn from memory, will be as close to detail as possible. Very probably, too, the case in question may furnish ideas to a greater number of young workmen under our heading than any other, being as it was, and so often is, one of apparent difficulty by reason of a somewhat limited amount of choice material to draw upon, and the scene of intended operations necessitating a rigid economy of space. In this instance, some 300 guests were expected for the nonce to be comfortably accommodated within a pretty English home not palatial in size. Lest it should be inferred, however, that there was little to do it with and little to be done, it must be said that such was not the case—this case. Our head gardener was a man who veritably gloried in difficulties, each difficulty being his opportunity.

The preliminary operation consisted of a conference between mistress and man at an early date, with a general survey of the whole routine of operations; the latter taking notes upon the spot of those salient points where it was possible for a cunning hand to contrive an especially good effect. There was sufficient confidence placed in him as a man of resource; henceforward he had *carte blanche*, no further questions being asked or orders given. Coming to the eventful day when in a few hours all was transformed into what one distinguished guest was pleased to call "Fairyland," neither hurry nor confusion was apparent, and two hours were yet to the good when the host, after a critical survey of the completed work, said to our friend, "You have surpassed yourself!" Before going into details one thing must be impressed, obvious as it may be—viz., that the "head" had studied and planned every detail to the extent that all which worked so smoothly, and everything which seemed to fit so admirably into its place, was, in fact, as regards plans, the survival of the fittest, affording the best possible under the circumstances. It must also be added that his hands—his own hands—had fashioned considerable addenda to the general effect in the way of some amateur carpentering; but of this more anon.

At the entrance porch some room was afforded in one corner for a bold group of evergreen shrubs, sufficiently tall, and not crowded out of character. A younger hand at the work would possibly here have placed something more elaborate, if not more showy, yet less suited to the exposed position, and thus begin big at the beginning. To do so would be a mistake. It is always better to do as an old friend does in showing his houses, begin modestly, and lead up to the highest and best. In the entrance hall, a square space, and somewhat limited for room, two graceful groups were disposed in the facing angles, each consisting of a central plant of a light feathery Bamboo, springing from a cluster of Ferns, encushioned in moss, these Bamboos being sufficiently tall to arch over the folding doors. The inner hall and staircase from their greater importance were more lavishly treated. This hall, being heated by some half-dozen circular coils, enclosed in ornamental cases, with flat marble tops, they served admirably as pedestals for fine specimen Palms in tubs, throwing them well up into space. One such near the staircase foot was utilised as a vantage point for a noble Dicksonia antarctica, the plant in this position having an almost unique effect.

The tubs of these large specimens when stood upon the coils admitted of no other concealment than the virgin cork with which they were permanently covered; nor in fact did anything else appear necessary, although a few sprays of Ivy, secured by small tacks to the cork in a natural manner, was a pleasing adjunct. For brightness each available nook in this apartment contained within a circumscribed space a group of gay flowering plants, chiefly white and shades of red, all nicely fringed and interspersed with Ferns. The plan of keeping each variety of plants employed distinct in groups was commendable, giving a decided character tone, to which indiscriminate mixing is inimical. This apartment being for the occasion used as a promenade, seats and lounges were arranged to form a part of the general scheme. A turn on the staircase at right angles was not, as a vantage point, overlooked, and doubtless interested visitors wondered how such a marvellous specimen Bamboo grew in the high, narrow, cork-covered box, made to fit the angle. However, there are tricks in all trades, and a little making up at a pinch (including splicing) is quite justifiable on these occasions.

The more restricted space of a corridor leading to the principal rooms admitted the introduction on one side only of a single line of Rex Begonias banked in moss, the moss being retained in its place by two parallel lines of string which, when stretched tightly, was invisible, and prevented its being swept astray by ladies' dresses. A simple device which should be invariably employed for all floor groups where the contingency is likely to occur. Rising from the line of Begonias, at intervals some cork-covered stems were gracefully entwined with climbing Asparagus, and surmounted with a plaut of Nephrolepis exaltata, to hold which the cork had been left sufficiently high above the rustic stem. A dozen shields, cut from ¾-inch boards, and faced with red baize, hung upon the walls of this corridor at the eye level, and had a particularly good effect. These were outlined with a single row of Golden Holly leaves, each leaf partly overlapping its neighbour, thus hiding the tacks with which they were secured. In the centre of each shield a monogram had been neatly worked in the same material—Holly leaves. This, and other similar work, had been done at leisure intervals some days beforehand.

In the reception room proper, where the hostess received her guests, little extra to the usual drawing-room decoration was employed, cut flowers in vases and a few choice plants being the chief objects, with the exception of one table, upon which crimson and white Chinese Primulas were arranged *en masse*. From this the ball-room led, and here no grouping was permissible, although the ingenuity of our decorator had been requisitioned to hide a huge fireplace which had been called "particularly ugly." To fill it with plants would have been leaving it a fireplace still, not to speak of some encroachment upon space. The difficulty was overcome by improvising a screen to fill the whole space. This consisted of a skeleton frame, upon which wire netting was tightly stretched, the whole being closely interwoven with small sprays of common Yew, the same monogram previously noticed being worked out with similar sprays of the golden variety, and standing out in good relief on the dark background.

The margin is so narrow between success and failure in forming letters, monograms, or anything of this kind, that it must be here noted our artist was in this work *facile princeps*, and should any decorator doubt his power to execute similar designs, it is better not to attempt it. The head gardener in this case of decorating was, however, no mean draughtsman, and what is equally to the purpose, had acquired a trained eye which could not mislead him. Work of this kind is subjected to the highest criticism, and with those who would excel, mediocrity in the form of "amateurish" results is intolerable. Perhaps there was no more severe critic of his own work than himself, and he had, too, that rare gift of asking an opinion without seeking for praise. An improvised orchestra in the ball-room need not detain, it was suitably enclosed by a screen, such as that described in the decorations of a public hall. We have now two apartments to glance into, one the refreshment room, the other the supper room, and the former, in which the tables were laid as buffets, needs but brief mention. Pretty plants of Geonoma gracilis in vases, and finished off with Panicum variegatum, were disposed at intervals upon the tables, and home grown fruit was tastefully dished up with the foliage of an old Barbarossa Vine, glorious in its dying tints. These were the chief features, although an elegant centrepiece on a principal table, composed of Grapes with the wood and foliage attached, cut from the same old Vine, was worthy of notice.

In the supper room a contrast was provided to anything hitherto noticed by the use of one colour only. Candles, candle-shades, cut flowers, were all in harmony, yellow being the colour. This, of course, had been one of the arrangements made in the *pourparlers* 'twixt mistress and man, and the time and season allowed for a quantity of the common Daffodils being forced for the occasion. As centrepieces on the chief tables, and generously distributed in small vases with an ample supply of their own foliage, a bright, fresh, and pretty effect resulted, whilst the mirrors of a large overmantel were lightly and gracefully adorned with long pendent strings of Smilax. In the peaceful retreat of a conservatory near at hand, which had for the nonce been deprived of most of its larger plants, our decorating hand had been chiefly employed as an illuminating one; the remaining plants had been temporarily grouped to afford as much clear space as possible. Taken as a whole, nothing could have been better done, and the infinite variety and good taste in evidence left nothing to be desired.—DECORA.

(To be continued.)

WALL TREES AGAIN.

A SEARCH FOR GOOD SAMPLES.

THE self-complacent, semi-caustic, tone which "H. D." seems fit to adopt, and his fruitless, fishy superfluities on page 334, may exhibit a certain amount of controversial cleverness, and thus, perhaps, serve their purpose, but yet he seems to shudder at, and would teach a lesson on, the avoidance of "bad form!" A youthful gardener who poses as an Alexander of old and conqueror of all, crying for more victims—for "Traveller" and "Invicta," or whoever may have the temerity to come forth to be slain—will find, as he gets older, that this is not the "form" on which he will congratulate himself then, any more than others with matured minds will congratulate him now. It is evident he has not, as he vainly imagined, frightened a "Traveller" away, and even "Invicta" may possibly be heard of again. I, as one who commenced the training of fruit trees fifty years ago, and am training them still, cannot be supposed to know so much about the subject as one whose chief boast, so far, rests on his training (and what a confession it is) "Morello Cherries!"—planted and formed by somebody else. A great feat surely, is this, and even such as a garden boy of the olden time, if he were a little extra "pert,' might glory in.

But justice must be done even to one who has learned so much more in a short career than others have in a long one; for this short service man tells us that the training of some other trees, not named, stand as "monuments" of his skill. We hear something from time to time of the self-assertiveness, not to say vanity, of the "new woman," but the question is now opened whether new mannism is not the greater phenomenon of these modern days.

"Traveller," I had thought, was a little too severe in his pointed reference to "mutual admiration associations." That they exist is well known, but it had not occurred to me that there were many of them in the community of gardeners. But "H. D." has forced to the front the suspicion that there may possibly be even self-admiration societies, each composed of one member.

Not content with indulging in up-to-date cynicisms in one article, and feeling safety, probably, in the senility of an "old" gardener, the member of one of these societies gets on his bike, and on another page tells us he went in search of evidence in support of his contention of the present superiority of wall trees over those of the past. A society on a bike fishing for creditable wall trees is not a common occurrence. But why the necessity for this search? Were there no well-trained fruitful trees at home? If there were, why the "risky undertaking?" One thing seems clear—namely, that Mr. Kean has better trained and more productive trees than have been raised by a whole society. It is a great compliment to him. They are good trees, and possibly the daring biker has proved a little too much. He did not pause to think, in the exuberance of his spirits, that, notwithstanding his discovery, somebody else had been there before him, and is able to say emphatically that those trees do not represent the miserable mongrels that are now so common in gardens. They are among the exceptions which prove the rule of the prevalence of the jumble of crooked and crowded branches on what are called "trained trees" in hundreds of British gardens. Their discoverer (second hand) is compelled to admit he would have to go "a long way before finding their equals." Just so, that is precisely my point. Really good wall trees are, indeed, too few and far between; yet those cited are not above the average of examples which were grown in nearly all gardens during the period when as much thought, care, and skill were devoted to wall trees, root and branch, as are now applied to Chrysanthemums, table decorations, or other work that absorbs so much attention.

Nor is such fancy work as this, however well and creditably done, a valid excuse for the unsatisfactory state of so many garden walls at the present day. It is a mistake to suppose that all experts in one kind of work are either incompetent or negligent in other kinds. First-class Chrysanthemums and wall trees are to be found in gardens where decorations are also conducted on an extensive scale; indeed, there are far more examples of spoiled trees in gardens where Chrysanthemums are grown in third-rate style, and "decorations" are of the most moderate character, than where the exact reverse is the case in respect to the two last named features.

The fact is, if a man has the knowledge and the will to grow and train wall trees well, so that they will be the pride of the garden, he will not rest contented to neglect them, and beyond all question the better they are trained the less time is required to keep them in order. Every man who has had actual experience with both kinds—the straight equi-distant and properly distanced branches, and the crude jumble of shoots laid in on the anyhow plan—of trees which he has had to bring into the most presentable and best-bearing condition knows that the facts are as stated, and whoever disputes them does so either through perversity of mind at the moment or through the misfortune of not having been properly trained himself in the work in question.

It is in all respects as easy to have the branches of fruit trees straight, as it is to have the rods of Vines free from awkward twists and turns this way and that, with the terminals pointing anywhere; and if there are ten of these well guided Vine rods at the proper distances, instead of twenty bent and huddled in anyhow—obviously the ten not only require about half the time spending on them that the twenty do, but the lesser number bear the better crops. It is precisely the same with well-managed wall trees, simply because there cannot be any other result; and if the trees do not develop the best of blossom buds on the best of wood, that of itself is evidence of faulty management of branches or roots, or both. It is generally both; but this is not the fault of the managers, say the excusers of those who fail, but of the "decorations," or whatever may come in handy for the purpose.

The parrot cry of well-trained trees being the most costly to manage has gone on long enough. The idea is fallacious. It were as reasonable to say that more time is required to draw a straight drill than a crooked one. It may be to a novice or a bungler, but every good workman would laugh to scorn the very absurd proposition.

The object of not a few modern growers of fruit seems to be to rush up the branches to the top of walls and trellises in the shortest possible time, and they may gain in the fruit supply during the first year or two. It may even pay them to do this with Peaches, Pears, or Vines, and to uproot and replant every few years; but that is not the way to furnish garden walls as they used to be, and ought to be, furnished, for affording, not pleasure only to the trainer, but satisfactory yields of fruit over a long series of years.

Mr. Williams' Pears, above alluded to, were *not* "run up" in the rampant style with strong central branches reaching the top of the wall in "no time," and the lower ones dwindling away, leaving blanks to be filled up by Tomatoes, and calling it "making the most of the space." This may delude the frisky colts, and perhaps their young masters, but not the old "hunters" in gardening.

Having now stated facts which cannot be overturned by reformers and discoverers, however young they may be, and refined their taste, however great their self-sufficiency, or glib their pens, I retire and leave this particular one "H. D." to combat, as he longs to do, foemen more worthy of his steel, in "Traveller," "Invicta," or whoever may dare to meet him. It would, if they are also young, be a greater honour to vanquish them than the tottering rheumaticky old gardener who commenced work in the forties, and is shambling along yet, as well as he may, after his little "run."—MELTON.

TRAINING FRUIT TREES.

ON page 310 "S. B. O." has contributed some very seasonable and sensible remarks on the above subject. He does not record his vote in favour of my previous arguments; but that is a small matter. We want to arrive at the truth, even though the pet theories of some are roughly treated during the process. "S. B. O." is, however, labouring under two wrong impressions, which I think I can prove to be such.

In the first place, he does not think that increased floral decorations can have led to decadence in the training of fruit trees because the men entrusted with decorative work do not attend to the training of trees. That is just the point. At one time, in both large and small establishments, the young men in the houses used to turn out *en masse* during the winter time to prune and nail in fruit trees; now, in consequence of the time they are obliged to spend in floral arrangements at the mansion, they have a hard struggle to scramble through the work of the glass department. There is no time while daylight lasts for them to attend to outdoor trees.

In his concluding paragraph your correspondent asserts that good fruit is as much admired as any floral arrangement on the dinner table. "S. B. O." is evidently not up to date in this matter, for although—from a gardener's point of view—I much regret it, yet it is nevertheless a fact that in the "highest circles" fruit is seldom—in many cases, never—placed upon the table. The only opportunity guests have of admiring it is when it is handed round.—H. D.

PRIZES FOR WILD FLOWERS.

I THINK it is an important question, and one which demands the serious attention of all societies, as to whether prizes for wild flowers should be continued at shows. I have heard several botanists say these prizes do a great deal more harm than good. If prizes were given for botanical specimens properly named I could see some object in the prizes being offered. It is certain that wild flowers are getting more rare every year.—A SECRETARY.

[It is not from any fear of children who compete for the prizes offered for bouquets and collections of wild flowers at summer shows exterminating the wildings by cutting them that we object to the competitions which generally prevail. They do not take the roots. We object to the system in vogue because it teaches nothing, not even good taste in arranging flowers. The huge, closely packed bundles for which prizes are awarded are nothing less than floral monstrosities; and the thoughtless manner in which prizes are given for so many bundles, leads children to think the more flowers they can gather and pack together the better.

We have seen pleasing exhibitions of wild flowers of twelve distinct kinds, with names attached, one kind only in a bunch, and the bunches not too large for wineglasses if these were deep enough for holding them. We have also seen classes for the most tastefully made bouquets of wild flowers and Grasses, to be loosely disposed, not closely packed, and the bunches not more than 6 inches across, result in creditable competition. The gathering of wild flowers for showing on those lines becomes an educational exercise, and would be unlikely to result in their extermination.

Danger in that direction lies not in the plucking of stems of attractive spikes by children, but in the digging up of roots by searchers for and collectors of rare kinds. These "collectors," as was said not long ago in one of the daily papers, are apt to become deadly foes of the true lover of Nature, and an incident was cited as an example. One of these searchers, as likely as not wearing spectacles, was taken to see a solitary specimen of an uncommon plant growing in a meadow. He regarded it for a moment to make sure of its identity, then said, "I congratulate you, sir, on having such an interesting species in your district," and forthwith went down on his knees and—dug it up. Those kind of individuals are the real Vandals.

The present system of exhibiting wild flowers, and granting prizes for them, is in our opinion indefensible, but to afford the young in rural districts no inducements for studying the flowers of the field and the wayside, or for arranging them in a pleasing manner, would seem to be going to the other extreme. If judges or others interested in the subject have any proposals for amending the stereotyped bundling system they will, no doubt, be welcome to other secretaries of shows besides our correspondent.]

ROSE MAMAN COCHET.

HAVE any of your readers noticed a curious disease on the leaves of this Rose? A friend found it on his plants and asked me to examine mine, when I discovered it on all my plants. It seems peculiar (at least, in my friend's garden and my own) to Maman Cochet, and under the microscope looks like a sort of crystallised salt. Specimen enclosed.—J. T. STRANGE, *Aldermaston*.

[On close examination the white matter on the upper surface of the leaflets was found to be mainly oxalate of lime and potassium, confined to that side. This, for some reason, has passed from the organic into the mineral form, probably from an excess of acid in presence of lime with a deficiency of potash for its utilisation. The appearance is common on the leaves of the Dog Rose in some seasons, especially on calcareous soils. The lower side of the leaflets is quite green, the upper side discoloured and covered with salt-like minute dots and splashes. Some call it "silver leaf," but this is a spring and early summer, not a late summer affection. A supply of potash and iron gives good results, of course, along with phosphate. We used three parts dissolved bones, two parts muriate of potash, one part sulphate of magnesia, and half a part sulphate of iron for a similar affection, applying 4 ozs. of the mixture per square yard in the autumn, pointing it in lightly.]

IS GARDENING DECAYING?

"TRAVELLER" has re-appeared upon the scene in the "nick" of time, for while one writer was wondering what had become of him he seems to have been penning his jubilant note. He writes in a style which many might consider carried conviction with it, but I am not sure that he has really convinced himself of the soundness of his despondent theories; they seem to me to be advanced as so much good-humoured "chaff." If "the men who are heard at the shows loudly glorifying their productions" are not taking up the matter in the way "Traveller" would like, it is not because their side of the case is the weaker one, but because they think they are doing something more to their advantage.

Is gardening decaying? Certainly not; it is only changing in form, as it has ever been changing. It is also greatly expanding in various directions. Grand plants in small pots are now grown by the thousands where formerly they were only produced by units. For a very moderate outlay, the dwellers in our large towns can now purchase such splendidly grown plants as only came within the reach of the affluent many years ago. A keen love of gardening is abroad among the masses; it is in innumerable instances making them contented and happy, it is bringing brightness into countless homes, where nothing but drudgery and want prevailed in the "good old times."

Can a "Traveller" point to any period in his long and, I think, useful career, during which Apples, Pears, and Peaches were better grown than they are to-day? Can he point to a time when perfectly coloured handsome bunches of Grapes were more numerous than they have been during the last ten years? Old exhibitors know well enough that the quality of the Grapes which used to win them first prizes would have to be considerably improved to win a third prize now at many provincial shows. Do not be too jubilant, "Traveller;" your "shell" has alarmed no one, and the only damage it seems to have done is to have stirred up the dust—which you show will not "help us to see daylight."

I see that special objection is taken to the remarks of one writer, who advances the increase of decorative work as the reason why in some places the fruit trees do not get the attention they used to. I can fully endorse that writer's remarks, for it once fell to my lot to manage a garden in which decorations on a gigantic scale were continually being carried out, and this had to be accomplished with only a slight temporary addition to the staff employed in the "old earl's time," when very little decoration was wanted. Can any reasonable man call this a "lame excuse" for the neglect of some other department of gardening? It matters not how much "delicate furnishing" there is to be done so long as the staff employed is proportionate to the work required. The order of the day in many establishments has been to reduce the labour and increase the ornamental and unproductive part of gardens. This has been the cause of the serious deterioration of real gardening in many places.

The truth is that gardeners do not now grow plants and crops for their own hobbies; they are obliged to cultivate such things as their employers require. Gigantic Heaths and stove plants used to be popular, few owners of gardens care for them now, as they cannot turn them to account for house decorations; they have, therefore, in obedience to that great natural law, "the survival of the fittest," to a great extent dropped out of cultivation. Orchids, on account of their rich beauty, are in many places the rage. Their culture is so thoroughly understood, that it is now as common to see splendidly grown plants as formerly to meet with miserable starvelings. Talk about the decadence of gardening, let any employer express the wish to have certain plants and crops grown in a superior manner, and he will find plenty of gardeners ready and able to carry out his wishes if the requisite means are forthcoming.

The splendid progress made in the culture of that lovely flower called rightly the "Queen of Autumn" is evidently a thorn in the flesh of "Traveller." The advance has been made by leaps and bounds, and Chrysanthemum men are in consequence justly proud of their achievements. If there is one class of gardeners who love their work more than another, it is those who take special interest in Chrysanthemums. They will work any amount of extra hours to give their plants the attention they require; in fact, the special attention given to Chrysanthemums is invariably done after the ordinary hours of labour. Certainly I have not yet seen a good gardener neglect other things for them; on the contrary, it is usual to find that where these favoured flowers are well grown, other plants and crops are well done too.

The chilly days of autumn are upon us, and we want something to infuse a little brightness into our daily lives. It is to be hoped, therefore, that "Traveller" will carry out the Editorial suggestion, and visit the November show of the National Chrysanthemum Society; he will there find the specialists engaged in "mutual admiration" rather than in "squabbling." If he will quietly fringe the circle, and then disclose his identity, I fancy he will meet with a warm reception, one not the less sincere because of his crushing blows.—CHRYSANTHEMUM LOVER.

RANUNCULUS AMPLEXICAULIS.

THIS is a very distinct and handsome plant, usually growing about 12 inches high. The leaves are greyish. The flowers are pure white, in some varieties stained with yellow towards the base. It flowers in April and May, and is a native of the Alps of Europe. The woodcut represents a spray from a plant of this species whose large white flowers are very freely produced, and are very attractive. They are also useful for cutting, as they remain in good condition for a much longer period than the majority of single-flowered Ranunculuses, and wherever simple flowers are appreciated the plant should be grown. It is a border plant of very easy culture, thriving well without attention in ordinary garden soil.

HYDRANGEA CULTURE.

IT would be difficult to name any hardy flowering shrubs more suitable for growing in pots for the many forms of decoration for which flowering plants are required than Hydrangeas. They are comparatively easy to grow, and amateurs with a frame or a few hand-lights and a greenhouse may grow them to the same excellence as the professional gardener with more glass structures and greater accommodation. The latter by a judicious system of treatment and forcing, can produce them in succession over a period of several months, but with the former this can only be accomplished in a very small degree, and the amateur can succeed in bringing two or three batches into flower at different times so as to form a succession.

In order to grow Hydrangeas well in small pots it is necessary to have a few good plants of two or three varieties placed out in fertile garden soil in an open sunny position. This is the best system for the amateur, while those who want to force the plants into flower early in the season should keep a few stock plants in pots. These should have the protection of a cold frame until the weather is sufficiently genial to turn them outside without injury to the foliage made; in fact, prior to turning them out they must be carefully hardened so that they are not checked in their growth. Those grown in pots will yield cuttings in suitable condition for rooting before those are sufficiently ripe on plants growing outside, which can be rooted a few weeks later, and thus form capital successions to those taken from plants in pots.

PROPAGATION.

Cuttings from plants that have been grown in pots should be taken without further delay, for growth has ceased and flower buds are formed. If left too long the shoots become woody and too hard to root freely; in fact, they are a long time rooting in that condition, and many may fail to form roots; but when taken as soon as growth ceases and the formation of the flower buds has commenced, the wood is moderately soft and will root quickly and freely. The cuttings should be 2 or 3 inches in length, and cut clean below a pair of leaves with a sharp knife. The two lower leaves need not be removed, but inserted with the cuttings into the soil. The cuttings root equally as well without the leaves as when retained, but they assist in the development of the flower bud already formed. They should be inserted into 2-inch pots in a compost of good loam and a little sand; a little of the latter may be used for the base of the cuttings to rest upon. After insertion a good watering should be given, and the cuttings placed under hand-lights where a temperature of 60° to 70° is maintained. The hand-lights should be made air-tight and kept perfectly close and shaded from the sun until the cuttings are rooted. It is possible to root the cuttings by this method without exciting them into fresh growth. I have tried various ways of rooting them without pushing them into growth, and the system devised has answered as well as any. If the plants are left in heat after they are rooted they frequently start into growth, but this must be avoided by gradually hardening them to the conditions of cold frame. If this is carefully done, and the young plants are given cool treatment as early as possible after they are rooted, they will not fail to perfect and ripen their buds and stems.

PREPARING FOR FORCING.

The young plants when rooted should be grown in a cool place until the approach of frost, when they can be placed in a frame where frost can be excluded. Earliest plants usually occupy a position in a vinery at rest until the commencement of the year, the later plants being kept in cold frames, and protected with mats if occasion require. These plants are hardy enough and will bear frost, but it does them no good, and therefore should be avoided, for it frequently ends in the destruction of their foliage, which I endeavour to preserve.

Another, and a very reliable system of preparation for early forcing, is accomplished by rooting a good number of cuttings in the spring. The cuttings are perfectly soft, and thinned out from the plants in cold frames after they have made sufficient growth for the purpose, that are intended to supply cuttings in late summer. These are rooted in brisk heat, either in the propagating frame or under hand-lights in a warm house,

FIG. 53.—RANUNCULUS AMPLEXICAULIS.

Each cutting is inserted singly in a small pot, and directly they are rooted they are gradually hardened and placed in cold frames, giving them abundance of air until the weather is sufficiently genial for turning them outside. When the small pots are well crammed with roots, which is generally the case by the time the plants are placed outside, they are transferred into others 4 inches in diameter. The soil, which consists of good fibrous loam, sand, and one-seventh of decayed manure, is pressed as firmly as possible into the pots to insure a dwarf sturdy growth.

After potting, the plants are arranged in an open sunny position. Sometimes they are plunged to save labour in watering, but when this is done care is taken not to allow them to root outside their pots. The plants remain in this position until autumn, when they are placed under cover and treated the same as those rooted at this season of the year. These are only potted once during the season, and the result is plants with large foliage and stout thick stems not more than 6 inches high by the time they are housed. Plants prepared by this method are certain to produce early in the season enormous heads of their beautiful flowers. —B. T.

H. PANICULATA GRANDIFLORA.

IS this grand hardy shrub as extensively grown as it ought to be? It is certainly one of the most valuable additions that have been made to our shrubberies of recent years. Its huge heads of flowers are at the present time (September) most imposing, and arrest the attention of all who see them. Its hardiness, too, has been proved for several winters, which it has passed through unscathed in the southern counties; but in a garden in a cold district in the north it was injured, and as it looked

rather unsightly, was cut down by the owner under the impression that he would secure stronger growth from the base. He has secured such growth, and also, what he did not expect, grander heads than the plant ever produced before. This he regards as a lesson, and he is so convinced of its value that he intends cutting the plant down again, as he is certain this is the best method of managing it, or, in other words, growing it as an herbaceous plant.

There are now many plants of this distinct and fine Hydrangea grown in different counties, and it would be well if some of them could be cut down by way of experiment. There can be little to lose and may be much to gain, for certainly the heads of flowers alluded to are extraordinarily fine. Grown on the cutting-down system, and in richer soil than is usually found in shrubbery borders, it is fair to suppose that the heads would be still larger, and large beds of this plant with a background of shrubs would form a striking feature at this period of the year in any garden.

The plant is readily propagated by cuttings of half-ripened wood taken from the plant after flowering, and inserted under hand-lights placed on the shady side of a wall or hedge. Younger growths can also be employed for cuttings, and these will root quickly if inserted either singly in pots or a number together (the first method being preferable), and placed under hand-lights or in a close frame until they are rooted. If propagated in heat, give a good watering after insertion, and keep the cuttings close and well shaded afterwards until they are rooted; cuttings possessing two joints—one to be in the ground and the other just above the soil—will suffice.

The chief secret of flowering it well in a pot is the thorough maturation of the wood. After flowering, the plant should be hardened and placed outside, then in autumn or early spring should be closely pruned back; if one pair of eyes is left on the new wood that will be ample.—R.

TRAVELLER'S TALES.

EVER and anon some simple subject brings in its train a host of arguments; good enough in one way, valuable in another, provided that the chief object is kept well in view and no descent is made into petty personalities. This in allusion to the controversy anent the decadence of wall tree culture in particular, and gardening in general. To the latter phase I have ventured to repeat the query which is appended to the heading of the article on page 308. From the intense interest that "Traveller" presumably takes in the matter, one must try to suppose that his primary object is the welfare of the cause—of gardening and of gardeners; hence we will endeavour, like "The Autocrat of the Breakfast Table," "to love him none the less for anything he has told us."

Whether his mode of attack is the best means to that end is another matter, and one open to question. "Methinks the gentleman doth protest too much." What would he have when, in flinging down the gauntlet from "the rock bed of unassailed accuracy?" Has he not judged—prejudged the whole community, and found them wanting? If this is admitted, *cui bono?*

I am fully aware that "Traveller's" indictment offers temptation to engage with him in wordy warfare, and that he has baited his hook with such choice morsels that some at least may bite to their cost, for I doubt not but he will land his prey somewhere upon that solitary "rock." It scarcely appears possible to face this question, "Is gardening decaying?" without drifting into some of those side issues the travelled one apparently dreads, because to get at the truth analysis is necessary, and to analyse brings us to details. However, 'tis as well sometimes to see ourselves as others see us, but in this case what a spectacle 'tis, surely!

Should "Traveller" return to his tale of woe, one hopes he may be able to point the way to better things. Who among the whole "fraternity," young or old, is not willing to learn, and is learning daily by experience; and seeking, too, the light of knowledge from others who may have it to impart? So far our "trenchant 'Traveller,' who has suddenly appeared to sparkle over a degenerate world," dazzles but to "lead astray;" and at present appears to have enveloped himself in conviction-proof armour, forged upon the anvil of imagination.—VESPA.

INFLUENCE OF FORESTS ON FARMING.—In a recent article, in which reference is made to the influence of forests on farming, the "Boston Transcript" says that soil, moisture, and heat are the three servants of the farmer. The soil he can regulate by culture and fertilisers, but moisture and heat seem out of his control. These are not out of the control of the woods, however, and the farmer by judicious management of his tree-lot can bend them to his ends. He can prevent or temper the effects of atmospheric changes, he can avoid the disasters of excessive rainfall, and he can manage the water to his own benefit. It is explained that the snows of winter are conserved by the shade of the trees, and do not rush away at the earliest moment of sunshine to swell the spring freshets; the loose soil of the woods, not hardened by the impact of the raindrops, holds the water and lets it percolate to the springs below; the tree-covered area catches more of the snow, and the shaded surface does not give up its moisture in evaporation; there is more water there, and means are present to prevent its waste, so that the subsoil distribution is better and stronger, and it is the subsoil waters that are the farmer's standby in ease of need.—("Garden and Forest.")

FOREIGN CHRYSANTHEMUM SHOWS.

THE interest in the Chrysanthemum on the Continent is shown by a list of exhibitions to be held, which appears in the current number of "Le Chrysanthème." Those whose dates are already fixed are given as follows:—In France, 4th November, Bourges; 4th to 9th November, Montpellier; 6th to 10th November, Orleans; 10th to 14th November, Paris; 13th to 15th November, Havre; 17th to 21st November, Dijon. In Belgium, 6th to 8th November, Brussels; 14th and 15th November, Namur. In Switzerland, 17th November, Geneva. In Germany, 13th to 16th November, Carlsruhe; 14th to 16th November, Munich. Other shows, the dates of which are not fixed, will be held at Chambéry, Frankfort-on-the-Main, and Strasbourg.—P.

WELSH CHRYSANTHEMUMS.

I READ with interest your weekly notes on Chrysanthemums, and, living so far from any grower, I should be very glad of your opinion of the enclosed leaves in comparison with those of growers in more favoured situations. I have not had the pleasure of seeing any other plants this year. With regard to the variety Baron Ad. Rothschild, which is mentioned by your Irish correspondent, it does not lose its bottom leaves here any more than do the other varieties, but it goes spotted all up the plant, as you will notice by the enclosed. During the six years I have been here I have never seen an earwig on any of the plants, and mildew is almost at vanishing point every season. The Japanese this year are much dwarfer on the whole, while some of the incurved are a trifle taller.—WM. MABBOTT, *Dowlais.*

[Our correspondent has sent us fifty-four leaves of distinct varieties, and as each one is named their foliage characteristics can be seen at a glance. In texture the leaves are perfect, while the substance is no less inferior, as may be judged from the fact that five leaves weigh 2¼ ozs., the heaviest one turning the scale at just over half an ounce. They are most creditable, and we shall be pleased if Mr. Mabbott will send us half a dozen blooms to see if they are commensurate with the exceptional excellence of the leafage.]

PREVENTION OF THE CHRYSANTHEMUM LEAF MINER.

IT is now nearly a year since I sent you some leaves of Chrysanthemums and Cinerarias very badly infested with the Chrysanthemum leaf-mining maggot (Tryptera Artimisæ) and asked your advice for preventing the same this season. Amongst the preventives you gave me was one I determined to try—namely, putting pieces of cardboard coated with Myocum gum in split sticks, and place among the plants for the purpose of catching the fly. I am glad to testify to the excellence of this plan. Our plants are mostly grown for large blooms, and in their summer quarters were trained to a wire trellis. On the wires I hung the gummed cardboard the second week in June, and I have kept them well coated with gum until we housed the plants this week. We succeeded in catching many flies, and the very few maggots that did get into the leaves were soon settled with the thumb and finger. Other collections in the neighbourhood are, as usual, literally infested with them. I send you a few leaves for your inspection, picked at random from the plants, which are (in spite of the very wet season we have had) fairly well ripened. I advise all growers who are troubled with the leaf miner to try the plan above mentioned. I also adopted it with the Cinerarias, and up to the present there has not been a single maggot in the leaves.—J. C., *Lancashire.*

[The leaves sent were clean, fresh, and with no sign of insect or other pests on them.]

CHRYSANTHEMUMS AT OVERCLIFFE, GRAVESEND.

ONE of the most promising collections of Chrysanthemums I have seen in the neighbourhood of Gravesend is under the management of a very promising and industrious young gardener—namely, Mr. H. Carpenter, gardener to Captain Marsden, Overcliffe. His plants are well grown, strong, and healthy examples, promising to produce exceptionally good blooms. They are of medium height in every case, as the whole of the collection was cut down in May and early June. Fairly dwarf plants are, in his case, almost a necessity, owing to the inconvenience of housing very tall plants.

Having been grown throughout the summer in an open, sunny position, without any shade for the greater part of the day, has undoubtedly proved of great assistance in the building up of the stout growths, with their bold, leathery, deep green leaves, furnishing the plants well down to the pots. The wood is becoming thoroughly ripened, the best buds have been secured, whether crown or terminal. In most cases the crown bud, or the first bud showing after the cutting down, has been selected.

Mr. Carpenter confines his selection of varieties chiefly to the Japanese section. About 100 plants is the number grown, all varieties of proved excellence. Those varieties having the most forward buds included Mutual Friend, Mons. Freeman, W. Seward, Miss Watson, Mrs. C. H. Payne, Etoile de Lyon, Duke of York, W. H. Myers, Beauty of Exmouth, Lady Saunders, W. H. Lincoln, Henri Jacotot Fils (this variety and

Mr. H. Broomhead had the lightest-coloured foliage in the collection, and the latter will be rather late in blooming), Van den Heede, Chas. Davis, E. Molyneux, J. Shrimpton, Viviand Morel, and President Borel. —E. D. S.

The Chrysanthemum Era.

Has "Traveller" (page 308) had a bad journey? Can it be that because modern gardeners did not respond liberally to his blandishments he penned that finely rounded sentence for the information of his "House":—"They are imbued with one impression, that the universe was designed specially for Chrysanthemum growers, and will revolve round them to the end of time." A fine burst of eloquence, truly. So well rounded, indeed, as to have no point.

This puerile tilting at the Chrysanthemum has been indulged in ever since the modern gardener discovered that by its aid the conservatory is the brightest at the season of the year when it was the dullest and dreariest in the good old times. The modern gardener is enabled, also, to keep the supply of cut flowers to the highest pitch of abundance, and this notwithstanding the fact that the demand now, at the lowest estimate, is in the proportion of twenty-five to one of that in former times. There are very few nurseries where the Chrysanthemum is not largely grown and its merits duly appreciated. "Traveller's" condemnation of it can only be ascribed to the fact that in the gardener's hand a sufficient home stock is raised without troubling the order seeker. In that case the sensible course would be a change in methods, for the Chrysanthemum is gathering strength as it goes along in its brilliant career.

"Traveller's" attempt to attribute Chrysanthemum culture as a cause of his alleged decadence (forsooth!) of gardening is a trifle amusing. He does not seem to know that successful Chrysanthemum culture necessitates the highest cultural knowledge. The gardener who succeeds in producing high-class flowers need have no fear of his abilities failing him in dealing with other subjects. A single day's drive to the different growers in well-known Chrysanthemum centres similar to Hessle or Liverpool will easily convince all who know good work when they see it, that the most successful Chrysanthemum growers pay no less attention to all the other important branches of gardening which they practise with equal success. These men will show as perfectly finished crops of Muscat and late Grapes, as sensibly managed Peach and other fruit trees, as good collections of decorative plants, and as useful supplies of vegetables, as any coming within a similar area to which "Traveller" may be able to refer to in times previous to the advent of his special *bête noir*, the Chrysanthemum.

Perhaps it would be well to remind this "new star" that a declaration of war on his part involves the possibility of an invasion of his own territories. Like himself, I can remember the time when there were fewer "Travellers" than there are at present, and some of them may be unable to get the usual "line." In spite of all the advantages to be derived from and by these "gentlemen of the road," we draw the line at lectures on our incompetence, and beg to remind "Traveller" that times, tastes, and requirements have changed in a wide degree from those of the past; also that he will not find himself equal to stopping the clock, nor even set the hands back a minute, as it marks time in the progress of gardening, including Chrysanthemums.—Cedo Nulli.

WATERPROOF AQUATIC PLANTS.

This may perhaps seem an anomalous title, for few people comparatively are aware that the numerous forms of vegetation seen floating on the surface of lakes, rivers, and streams, or whose green form is visible below the water, are clothed in waterproof garments. This, though, is certainly the case, and it is altogether a great mistake to suppose that floating or even submerged plants are soaking with water. The surfaces of aqueous plants are covered with a thin cuticle or film of the nature of a super-glaucous bloom over the ordinary epidermis or porous skin, which effectually prevents them absorbing the wet, acting, in fact, as a perfect waterproof, so that the watery element they inhabit does not enter their tissues save and only when required by their organism, and in accordance with the same laws which regulate the absorption of water by land plants.

Any persons desirous of verifying this interesting fact, can do so by examining the water plants in their neighbourhood. Take, for instance, the Water Lily; they will find the upper surface of the leaves is covered with this cuticle or varnish, and that water poured thereon collects into silvery globules, and rolls off without actually wetting them. The existence of this cuticle on the epidermis of water plants, as a perfectly distinct slight membrane, was first discovered by the eminent botanist, De Saussure, nearly a century and a half ago. Subsequently this discovery was confirmed by Hedgwiz in 1793, and, later on, in 1834, by Brongniart, who alludes to it in his most interesting article on the structure of leaves. The exclusion of superfluous water from the inside of aquatic plants is further promoted by the numerous air cells in their interior, for these are more abundant than in land plants.

This can easily be demonstrated by cutting the stem across of one of the former and examining the section with the aid of a small microscope. It is thought that in certain cases the formation of these air cells is accidental, the result of a slight rupture of the interior tissues; but generally they are due to the ordinary operation of a general law, and they assume in cases a very beautiful appearance. There appear firstly triangular openings between the adjacent polyhedral cellules, these then enlarge at the expense of the area enclosed by their walls until they take the form of a six-rayed star. This is easily seen by taking a section of the pith of a common Rush, which, examined through the microscope, reveals a very beautiful object. It is in this way the large air receptacles in the interior of most water plants are formed.

So much, then, for the anatomy of the subject; as to their physiology, most of us know that the leaves of ordinary plants are a sort of filte through which the impure air is filtered of its carbonic acid and rendered again fit for respiration—that is, aërial leaves remove carbonic acid from the atmosphere. All plants do this, from the forest tree to the smallest blade of grass. Even poisonous species in this respect are public benefactors, transforming the pestilent air into a pure vivifying atmosphere. The same law prevails in aquatic vegetation. All animals which inhabit the waters are ever poisoning the element in which they live with carbonic gas; and all aquatic plants, from their queen, the noble Victoria Regia, floating on the majestic Amazon or in a lake or tank here, down to the smallest and most insignificant weed in a stagnant pool with its scum-like vegetation, are engaged in the grand work of absorbing the carbonic acid, and then oxygenating their native element, thus restoring its pristine purity and rendering it wholesome.

This is especially the function of those plants which grow wholly under water, for it is apparent that a great deal of the oxygen of floating vegetation passes at once into the atmosphere without producing much effect on the water. With submerged plants the case is different. Water always contains a certain amount of carbonic acid in solution, which of course enters the submerged tissues. Under the influence of light this carbonic acid decomposes—the carbon is left in the parts which grow green, and the oxygen is exhaled. This exhalation from the leaves of aquatic plants is beautifully seen in those submerged species cultivated in aquariums in order to preserve the health of the denizen fish. The oxygen collects on the leaves in the form of air bells, and a continuous succession of them may be seen to rise by the observer through the water and burst on arriving at its surface. These keep the water pure, and show that the chemistry of Nature is at work, and the carbon of the carbonic acid is being assimilated by the plants.

It is thus aquatic plants purify the water, removing its objectionable poisonous element. Air in the interior of these plants not only excludes the water, but gives them the buoyancy they require. When, therefore, observing the different forms of aquatic vegetation in the pond, stream, or lake, whether floating or wholly submerged, my readers should bear in mind how wisely and well the organisation of these water plants is constructed, both without and within, so that the water in which they live shall be kept out of them, being admitted only in proportion as necessary to carry on the changes connected with the progress of their existence and development to maturity.—Wm. Norman Brown.

THE YOUNG GARDENERS' DOMAIN.

Schizanthus.

These plants can be thoroughly recommended to anyone requiring an effective display of bloom with little trouble or expenditure. For the conservatory, dwelling house, or greenhouse they are extremely effective. It can also be used for vases and the decoration of the dining-room table with admirable effect. For ordinary purposes we find sowing the seed in 6-inch pots the best method. The seeds should be sown very thinly and covered with fine sand. Germination is rapid, and when large enough the young plants must be thinned, leaving five or six to a pot. Any ordinary soil will suffice to grow them in, although the best results we find are obtained by using two parts of good loam and one of leaf soil, with road grit or sand. Do not fill the pots half full of crocks, one large piece sufficing, over which place a good handful of half-decayed cow or horse manure. The soil should be made moderately firm, leaving ample room for watering, as they require copious supplies when growing, which should be given alternately with some kind of manure water.

Red spiders are very troublesome to Schizanthus in the summer months, and if not destroyed soon spoil the plants; but if grown in partial shade and kept well syringed they are comparatively free from these pests. They can be had in flower nearly the whole year by frequent sowings, but are more serviceable in the spring and autumn, as the flowers last longer then. The tall varieties—viz., pinnatus, p. roseus, p. candidissimus, appear to be the best adapted for pot culture, and are more effective if mixed when sown. Being half-hardy annuals plenty of air should be given on all favourable occasions.—J. L. G.

Asparagus Culture.

Plants belonging to this genus have during late years attracted considerable attention, and this, no doubt, is due to their usefulness. The graceful foliage is admirably adapted for cutting and mixing with flowers in glasses, for making streamers for bouquets, and for laying on the dining table. The dwarf varieties make elegant table plants, being just what is required to relieve such specimens as Crotons and Dracænas of their sometimes too bright appearance when placed on the table. They are very useful for the embellishment of the stove, greenhouse, or conservatory, whilst the tall-growing varieties are useful as climbing plants for covering pillars and bare walls.

Propagation may be effected by the aid of seeds or division of the root. Sow the seeds in January or February in pans of light sandy soil, and cover over with a piece of glass. Remove the glass as soon as the seedlings appear, and when large enough to handle, pot into 60's, using a compost of fibrous loam, peat, and silver sand in equal parts. Place as near the glass as possible in a moist atmosphere, where there is a temperature ranging about 70°. When these pots are full of roots transfer them into 5 or 6-inch, using a compost of two parts fibrous loam,

one part peat broken into lumps, one part sand, charcoal, and potsherds broken small, with an addition of artificial manure, and place back in the same temperature until they are well established, when a cooler temperature will suffice.

Plenty of water must be given them, and they are benefited by occasional waterings with liquid manure. They require shading from the bright sun, also abundant syringings amongst the pots, but only lightly on the foliage. Two good climbing varieties are plumosus and tenuissimus. Deflexus is very useful for hanging baskets, as also is Sprengeri. The growths of the latter when young hold themselves erect, and gradually arch over as they grow older, until they are straight down. It is also the best variety for cutting, as it preserves its vitality a great deal longer than the others. Two good dwarf varieties are plumosus nanus and albanense.

Mealy bug is the worst enemy, and may be removed by occasional dippings in the case of the dwarf varieties, and syringing the tall with a weak paraffin insecticide, as the small pinnules will not stand a strong dose.—ELVEDEN.

CARNATIONS IN BEDS.

CARNATIONS are now recognised by many growers as the most useful plants for either beds or borders, as with a good collection abundance of flowers may be had for a long period. Where cut flowers are in demand Carnations are of great value for either house or table decoration when tastefully arranged with their own grass and made to look as light as possible.

It is advisable where possible to devote a special bed to their culture, as far better results are obtained than when planted in a mixed border. If, however, this system is necessary a good compost ought to be prepared for them. Autumn planting is the best in most cases, as it saves the trouble of wintering in pots, and is undoubtedly advantageous to the plants, which become established and start growing much better than those wintered in pots. The beds may be made large enough for from four to six rows of plants, with a path on each side.

As regards the mixture of soil, no rule can be specially given. The cultivator must examine the natural staple, and should this be of a light sandy nature it will be found suitable after a top-dressing of wood ashes, lime, and soot, which should be thoroughly mixed with the surface soil when dug. If the soil is found to be stiff and clayey apply a top-dressing of sandy loam and lime rubbish in addition to the above. As soon as the layers are sufficiently rooted they may be carefully separated from the old plants, placed in boxes, and be firmly planted in rows 18 inches apart each way. Always keep the beds free from weeds, and apply a mulching of half-decayed manure, which will help to protect the roots in winter and prevent the surface from becoming too dry in the summer.

As soon as the flower buds appear an occasional application of liquid manure and soot water will be found beneficial. The flower stems will also require staking, so as to display the flowers and prevent them getting soiled.—J. F. D.

[By all means send the notes on Carnations in pots, as if thoroughly practical they will be of service to many young growers.]

HARDY FRUIT GARDEN.

Gathering and Storing Fruit.—The gathering of Apples and Pears should be continued as the various varieties become ready. Most of them are sufficiently matured when the pips are of a dark brown or black colour. Any fruits that are not easily detached from the spurs may remain on the trees longer. It is seldom that every fruit on a tree is ready at one time. In gathering avoid bruising the fruits as much as possible. Store in single layers on clean boards or slates in a dark cool room or proper fruit room. Windfalls ought not to be placed with sound fruit, or indeed in the same compartment. Damaged fruits decay quickly, sooner or later emitting odours which may prove inimical to sound fruits, especially those approaching ripeness.

Plums.—The later varieties of dessert Plums may now be gathered, wrapped in tissue paper, and stored in a dry place where they will keep for some time. The varieties thus treated include Coe's Golden Drop, Ickworth Impératrice, Blue Impératrice, and Reine Claude de Bavay.

Filberts and Cob Nuts.—Nuts must be gathered in the driest weather, preferably after several days of wind and sun, so that the husks may be dry. After gathering lay out the nuts thinly in an airy structure to dry out every particle of moisture, and then store in jars, pressing the nuts closely together, excluding air with tightly fitting lids.

Strawberries.—Strawberries may still be planted, but the plants inserted ought to be those which have been well prepared, either in small nursery beds, or allowed sufficient space to develop good crowns and abundant roots between the rows of established plants. Plenty of strong plants are now obtainable where a liberal clearance of superfluous runners and the rooting out of weeds were carried out before any were crowded. Only the strongest plants should be employed now for permanent planting. The smallest may be inserted 6 inches apart in beds for the winter, planting finally in spring. Well cultivated and liberally manured ground should be selected for Strawberries.

Trimming Old Beds.—From force of circumstances or, it may be, neglect, Strawberry beds are occasionally left until this late period before runners are cut away and weeds removed. From such beds, owing to the rank growth, there will be few young plants of any value. Therefore, with a sharp knife, sever all attachment with the old plants. There is then a clear course for hoeing up the weeds and runners. This is a rough-and-ready method, applicable to the special conditions, but inferior to an earlier clearance of superfluous growths between the rows.

Mulching.—A liberal dressing of well decayed manure spread between the plants will prove of substantial service in affording nutriment for the roots, and assisting the plumping up of bold crowns for the next season's crop. It is not desirable to mulch young plants at this season, inasmuch as they are able to find adequate support in the soil.

Young Plantations.—A final clearance of runners may be given to recently planted beds, after that a Dutch hoeing will be beneficial.

Apricots, Peaches, Nectarines.—In order that the wood of these choice stone fruit trees may attain to a well ripened condition, the whole of the bearing wood which has produced the fruit this season ought to be carefully pruned out. Sun and air are then permitted to reach the growths from their point of origination to their extremities. Weakly or worn-out branches may also be removed. If at any point the retained or succession shoots appear to be crowded, and room cannot be found for the whole of them, cut out the ill-placed, crooked, or otherwise irregular growths. It is not necessary to prune now in a full and complete manner, but only so far as to admit sun and air freely. Branches and shoots crowded in one part and not in another may be temporarily regulated, finally overhauling and pruning away all that is necessary previous to the late winter tying-in or nailing.

Thinning out Wall Tree Branches.—The mistake is frequently made of allowing the main branches of wall trees to remain arranged too closely together. Now that the foliage is present is an excellent opportunity to rectify such an error. It may, in the case of horizontally trained trees, be necessary to remove every other branch, even at the risk of leaving the remainder rather wider apart than is essential. A foot distance asunder for the branches is suitable, and few trees do well and bear freely when the branches are at a less distance. Fan-trained trees, too, are frequently crowded. Some of the weakest and partially exhausted branches may, in their case, be removed, regulating the remaining at proper distances.

FRUIT FORCING.

Cherry House.—A structure devoted to Cherries is not common, but no fruit proves more useful for dessert in the spring. The house for Cherries should be light, well ventilated top and bottom, and efficiently heated; a lean-to or three-quarter span facing south for early forcing, or a span roof with the ends north and south for affording fruit in May and June. The trees may be trained to a trellis fixed 12 inches from the glass, border inside, and not made all at once. A 4 to 6 feet width of border, according to the size of the trees, is sufficient to commence with, draining it with rubble 9 inches deep, and on that a 3 inch thickness of old mortar rubbish. From 20 to 24 inches depth of soil is ample, but deeper at first to allow for settling. Good turfy loam, preferably rather strong lime rubbish from an old building one-fifth, and a sixth of road scrapings, form a suitable compost. The trees may be planted as soon as the leaves fall. Those trained to walls four to six years, and in a fruitful healthy state, also recently lifted so as bear removal safely and without check, are the most suitable. The border being put together compactly and the trees firmly planted, following with a good watering, and mulching with a little stable manure, will give a fair crop the first season. The most suitable varieties are Early Rivers, Governor Wood, and Black Tartarian. The roof-lights should be taken off and remain so till the beginning of next year.

Cherries are readily forced in pots, and give a long succession of fruit. The house may be heated for forcing, or a cool one, well ventilated, and as the trees ripen their crops, they can be placed outdoors. The trees should be secured at once, and if they require a shift into larger pots, attend to it without delay, disentangling the roots at the sides of the ball, and cutting back any straggling and thick ones. Provide good drainage, and ram the soil firmly. Trees that are in as large pots as desired need only have the drainage rectified and the surface dressed; or the drainage may be cleared away, a few inches from the base removed, the roots shortened back, and fresh soil given as advised for borders, with a fifth of well-decayed manure, removing also the loose surface material and supplying rich compost. For forcing in pots, Early Rivers, Belle d'Orleans, Empress Eugénie, Governor Wood, Black Tartarian, Black Eagle, Elton, and Mammoth are good. For a cool house, Belle d'Orleans, Early Rivers, Early Red Bigarreau, Empress Eugénie, Bigarreau de Schreken, Governor Wood, May Duke, Black Eagle, Archduke, Nouvelle Royale, Florence, and Late Duke. Those are compact growers, and the following large growers: Early Jaboulay, Black Tartarian, Bohemian Black Bigarreau, Elton, Reine Hortense, Bigarreau, Bigarreau de Mezel, Mammoth, Duchesse de Palluau, Bigarreau Napoleon, Belle Magnifique, and Tradescant's Heart.

Cucumbers.—The latest plants which are to afford a supply of fruit about the new year should be placed out on ridges or hillocks, training with a single stem to the trellis, up which they may be allowed to advance two-thirds, when pinch off the lead. Those not having the convenience of a Cucumber house may secure fair supplies of winter fruit by growing the plants in pots or boxes, training the growths near the glass over the paths in stoves, fruiting Pine houses, or other well-heated structures.

Plants in bearing should not be overcropped, or the fruit allowed to remain longer than it is fit to cut, removing all deformed fruit in a young state. Maintain a night temperature of 70°, 5° less in the morning, 75° by day, up to 85° or 90° with sun, admitting a little air at the top of the house at every favourable opportunity, and keeping the evaporation troughs eharged with liquid manure, floors damped with water about 8 A.M. and 4 P.M., dispensing with the syringe over the plants. Reduee the supply of water at roots, but not so much so as to cause flagging. A little sweetened manure sprinkled on the beds oeeasionally will benefit the plants through the waterings, washing their elements into the soil and the ammonia given off, but this must not be excessive, or the foliage will be injured. Keep the foliage thin and the glass elean, so as to seeure thoroughly solidified growths.

Melons.—The end of the Melon season, as regards those grown in frames and pits heated with fermenting materials, is approaching, though fairly good fruit may be had up to November, especially of kinds that will keep some time. Any fruits approaehing ripeness should be eut with a good portion of stem, and placed in a house with a gentle warmth, where they will ripen, and be weleome additions to the dessert.

From houses a supply of fruit will be kept up some time longer, the latest fruits only swelling now. Suffieient moisture will be secured to this crop by damping in the morning, and again early in the afternoon, affording water to the roots moderately ; a supply once a week will in most eases be suffieient. All superfluous laterals should be cut out, so as to afford the prineipal foliage the benefit of the autumn sun. Plants with fruit approaching ripeness should be kept dry, and a brisk heat maintained with rather free ventilation, the temperature being kept at 65° at night, 70° to 75° by day, rising to 85° or 90° from sun heat, affording a little air at the upper part of the roof whenever the weather is favourable.

Peaches and Nectarines.—*Earliest House.*—The trees are at rest, bright and promising in appearance, the buds not too large or over-developed, and likely to retain their hold on the trees. Where the roof-lights have been removed the borders will have been thoroughly moistened, and this, with the invigoration eonsequent on exposure, is the best safeguard against the buds falling. The trees must be pruned and dressed with an inseetieide, thoroughly washing the woodwork with soap and water, the glass with clear water, and the walls with limewash. Tie the trees to the trellis, everything being forwarded so that a start can be made without delay at the proper time. Let the lights remain off until the time of elosing the house. If the lights are fixed the inside border must not laek moisture, and air must be given to the fullest extent, insuring thereby as complete rest as practicable under the eireumstances.

Second Early House.—The trees have shed the leaves. Trees that have strong wood, which takes more time to mature than the moderately vigorous, must not be exposed until the growths and foliage are well matured. The exposure of the trees has an invigorating effeet, insures perfeet rest, and the rains do mueh to free them of insects, besides properly moistening the borders. When the foliage is all down the neeessary pruning, dressing the trees with an insecticide, and cleansing the house should be proceeded with, removing the loose surface soil down to the roots, and adding fresh material, but not eovering the roots deeper than 2 or 3 inches. In the ease of fixed roof-lights watering may be neeessary ; under no eireumstances must the trees be allowed to become dry at the roots.

Midseason Houses.—If the trees are in a satisfactory condition the border will be sound, but when indifferent in fertility it may be necessary to have reeourse to lifting, the wood being firm and the foliage beginning to fall. It must be done with dispateh, all the materials being in readiness. Provide effieient drainage, shorten strong roots, and bring any that are deep near the surfaee, employing the compost moderately firm. Good loam, rather strong, with an admixture of a sixth of old mortar rubbish, will grow Peaehes perfectly. If the soil be light add a fourth of elay marl, and if very heavy, a similar quantity of road scrapings. If the soil is deficient of calcareous matter add a sixth of old mortar rubbish. Avoid manure, except at the surface. Give a good watering, and the roots will soon get established in the fresh compost. Trees judiciously treated at the roots whilst they have foliage seldom fail to set and stone the fruit satisfaetorily.

Borders that have the surfaee a soapy mass, and it is not possible to remove it, may have a good dressing of quieklime quite an ineh thick, mixing it with the surface soil as deeply as the roots allow without much disturbanee, supplying quiekly acting top-dressings in the spring.

Late Houses.—Oetober Peaehes are quite as much valued as those of May, as they are fine in appearanee, and when properly supplied with moisture and nutriment during the growing season juicy and well flavoured. Sea Eagle is one of the best—large, showy, good flavoured, with a juicy flesh, free of the stringiness and mealiness too prevalent in some late Peaches. As the wood in many late unheated houses is not too ripe, the house may be kept almost elosed by day so as to secure a good heat, admitting sufficient air to insure a circulation, eontinuing the ventilation at night. Any trees that have too gross wood should have a trench taken out as deep as the roots and about one-third the distance from the stem the trees eover of trellis, and left open for a fortnight, then filled in again firmly.

Pines.—*Plants Showing Fruit.*—These will be valuable when fruit is searce and dear, therefore afford such plants the best positions in the fruiting department. Maintain a temperature of 70° at night, 75° artificially by day, up to 85° to 90° with sun, closing at 85°, sprinkling the paths when their surfaees beeome dry, and oeeasionally the plants on fine afternoons. Keep the bottom heat steady at 85° to 90°. Examine the plants onee a week for watering, and if any require it afford a supply of clear liquid manure at about the same temperature as that of the beds. Care must be taken not to overwater the fruiters, as that has a tendeney to eause the fruit when eut to be blaek at the centre.

Plants to Fruit Early.—Queens are best for this purpose, but there is not always a certainty of their doing so unless they are given a period of comparative rest after making good growth. Plants intended for starting at the new year should be kept in a temperature of about 65° in the daytime by artifieial means, 60° at night, ventilating at 70°, closing at that, and allowing the bottom heat to fall to 70° to 75°. Water the plants only when necessary, but do not allow them to become so dry as to cause the foliage to become limp.

Young Plants.—All young stock should now be arranged so as to obtain the fullest benefit of light and air. As the sun diminishes a eorresponding diminution of temperature must take place at night, until it reaches the winter standard of 55° to 60° at night, and 65° in the daytime. Ventilate freely whenever conditions are favourable, paying particular attention to watering. Examine plants about once a week, and whenever one needs water give it eopiously at about the same temperature as the bed.

PLANT HOUSES.

Chrysanthemums.—These should be housed without delay, or injury from frost may result. After the plants are placed under glass syringe them freely, or their foliage will be liable to suffer by the dry atmosphere of the structure. Slugs are frequently carried into the houses with these plants. It is a good plan to look over the pots carefully with a light several nights in suecession to remove any that show themselves. Slugs may destroy some of the best blooms, while they prey injuriously upon the cuttings at a later date. If aphides are prevalent fumigate the house with tobaceo smoke. They are much easier destroyed at the present time than when the plants are in full bloom. Once the flowers are infested with these pests they are soon spoiled, and rendered useless for any purpose. Late kinds that are grown for cutting purposes only may be kept outside; but they should be placed where slight protection can be given them in case of frost. If these plants are to keep their foliage healthy the roots must be kept at work near the surfaee, and then those grown for large blooms will develop flowers of the best quality. This can be accomplished by applying stimulants in a weak state, and artificial manure in small quantities to the surfaee soil oeeasionally. Flat blooms that are both void of colour and substanee are frequently the result of overfeeding, whieh destroys the roots ; unless the latter are thoroughly active until the last well-finished blooms cannot be expected. Earwigs are often numerous, and they must be carefully watched for, as they soon devour the petals and destroy the blooms. Give abundance of air to plants plaeed under glass, so that the flower buds are not unduly hurried forward. It is also the best means of preventing damping in those expanding.

Calceolarias.—The earliest of these may be placed into 3 or 4-inch pots, according to their size. Grow these plants in a cold frame, but watch for slugs, which are particularly fond of them. Later plants may be pricked into pans and boxes according to the quantity grown. These may now have a light airy frame, and will do better than if kept in one with a northern aspect.

Cinerarias. The earliest plants of these will be coming into flower and will be useful in the conservatory. Later plants that need more root room should be repotted at onee. It is useless to repot those that are already showing their flower stems. Those for flowering in spring should be well cared for, beeause they are invaluable when the majority of bulbous plants are over. These plants will do for some time in cold frames. Give them abundance of air daily, and leave a little on the frames all night when mild. The watering of these plants should now be done in the morning. To those in their flowering pots that are well filled with roots weak stimulants may be given. Soot water in a clear state is very beneficial to them. Watch for aphides and destroy them direetly they make their appearanee.

Lilium Harrisi.—This is a useful decorative plant when in bloom, and ought to be grown in quantity. Medium sized bulbs should be placed in 6-inch pots that are well drained. The eompost may consist of fibry loam three parts, the remaining part being composed of leaf mould and sand ; to this may be added one-seventh of decayed manure. In potting the bulbs must be just covered. If the soil is moderately moist no water should be given. Stand the pots in a cold frame and fill the spaces between them with cocoa-nut fibre refuse, covering the surface with about 2 inehes of the same material. Failing this fine ashes will answer the same purpose. When subjected to this treatment evaporation is prevented and the bulbs soon commenee to root and grow. As soon as they show through the plunging material remove the plants to the greenhouse and apply water. If grown in quantity a low cool airy house will suit them well, or they may be plaeed on shelves moderately close to the glass. From one potting a long suecession of bloom may be obtained if proper treatment is given.

Callas.—If these are still in the open they should be lifted without delay, well watered, and stood behind a north wall until root aetion has commenced, when plaee in their winter quarters. Solanums, Bouvardias, Salvias, and other plants that are outside should be lifted and treated in the same way until they are established. If there is any appearance of frost while the plants are outside protect them by covering with mats.

Ivy-leaved Pelargoniums.—Plants that have been well ripened will, if placed under glass where a night temperature of 55° to 60° can be maintained, soon come into flower. If the plants have been standing outside they should have cool airy treatment for a week or two and then gradually kept close. Those well ripened under glass and reeently potted will in gentle warmth soon come into flower. Those for spring flowering

in 5-inch pots may be pinched and placed on a shelf where the temperature will not fall below 45° during the next three months.

Zonal Pelargoniums.—All plants grown for autumn and winter flowering should be under cover. Heavy rains and dull sunless weather are very liable to start them into a soft growth, and if this takes place the plants will not flower satisfactorily. Those placed in a suitable house if gradually kept close and finally subjected to a temperature of 55° to 60° will be in full bloom during the early part of November, a time when they are specially useful. Those not needed so early may have the protection of cold frames for a time. Give them abundance of air when favourable, throw off the lights during fine days, but protect them from frost and heavy rains.

French and Fancy Pelargoniums.—For early flowering these plants are best in 5-inch pots. For this purpose cuttings are rooted early, placed in 3-inch pots, and the point pinched out, or, better still, taken out when the cuttings are inserted. If this is done the plants start into growth with three or four shoots, and are established in 3-inch pots. From this size they should be placed into 5-inch pots, using a compost of loam and sand, with one-seventh of decayed manure. The soil must be pressed firmly into the pots to induce a slow sturdy growth. The plants should not be pinched again, but when potted stood on a shelf where the temperature during the winter will average about 40°. If the plants prepared for this purpose are too large pinch the remainder, give them the same treatment, and finally place them into 7-inch pots. Young stocks are preferable to old plants. The earliest of these should be given similar treatment to that advised for the young stock; the second earlies ought to be shaken out and repotted in smaller pots. Keep these close for a few days until they have commenced to root, when place on a shelf in any cool house. Cuttings that have been dibbled in outside and are rooted may be potted and placed on a shelf in a cool house. Late plants are often as important as early ones.

Fuchsias.—Cuttings that are just rooted may be potted singly into 3-inch pots. Stand these on a shelf close to the glass, where the temperature does not fall below 50°, until they are established, finally placing them where they can be kept at 45°. In this temperature they will grow slowly during the winter, and make excellent decorative plants early in the season.

THE BEE-KEEPER.

Seasonable Notes.

The fine weather of the past month has been beneficial to the bees, in marked contrast to that experienced a year ago. Bees have been daily on the wing, and those coming from colonies that are headed by young fertile queens have returned loaded with pollen, showing that breeding was going on apace. Stocks that were worked during the past summer for honey production, the queens of which were bred during the summer of 1896, were much quieter, and a less number of bees were observed on the wing than in the former case. This, at first sight, may appear strange, as the hives are crowded with bees, but the reason is the queens, having been worked at high pressure throughout the season, are now enjoying their well-earned rest.

Early in January, or at least six weeks earlier should the weather be mild, they will again commence their maternal duties, which will be continued throughout another season, or until they are replaced by young queens. In all probability those stocks which have queens of the current year, and according to present appearances are not as strong in bees as the older colonies, will be equally good, and in many instances better next spring, as the majority of bees hatched during the months of June and July will die off during the autumn.

More dead bees than usual were observed near their hives last August, owing to the excessively hot weather experienced. In some districts the honey flow was over at that date, and the bees remained at home, gaining an entrance to a weak unprotected colony, and making short work of their stores. Many complaints of robbing, and inquiries how to stop it, were made. When this takes place bees do not die of hard work, but owing to being in conflict with their neighbours.

Examining Stocks.

Before finally placing on the extra winter coverings it will be advisable to examine all stocks, so as to be certain they are in good condition for wintering. It will not be necessary to lift the frames out of the hive unless there is a special reason for doing so. A little practice will enable the bee-keeper to tell at a glance whether there is a queen in the hive, and if they have ample stores to tide over the winter. Choose the middle of a fine day for the operation. Remove the coverings and partly lift the quilt, look down between the combs, and if several of them have sealed stores the whole length of the frame which is visible from the top, they may at once be covered up without disturbing the bees.

If there is the least doubt in the matter, lift out two or three of the outside frames, and if these are not in a satisfactory condition the stock should be marked, and be at once fed with warm syrup, according to the recipe given in previous notes. If the majority of the hives in an apiary are of the same size and similar pattern, it is not often necessary to lift the quilt to find out if they are short of stores. The plan I usually adopt in my apiary, when I have a doubt in the matter, is to lift the back of the hive, and with a little practice any bee keeper may form a pretty correct estimate as to the amount of stores contained in each hive.

Queenlessness.

Owing to various causes stocks are sometimes found queenless at this season. Not an autumn passes, and the present one has not been an exception, but I have my attention called to this subject. It may be to a colony in which a young queen has been reared, and known to have commenced laying, but more often it has been to an old stock in which there was a queen of unknown age. In the former case it is difficult to know why a young queen should suddenly collapse. I have, however, had numerous instances of this. It has rarely happened, though, with a queen hatched in June or early in July. Queens hatched late in the season will often die in this mysterious manner. It, however, ought not to happen in an apiary where bees are kept in the modern frame hive. This will only take place when bees are left to take their chance and there is no system in their management.

If all the hives are numbered and a list kept of each, the age of the various queens, how obtained, when hatched, and other items of interest being placed under the number of each colony, all this may be entered in a small book which can be carried in the waistcoat pocket, and would be always at hand. It is not nearly so much trouble as one would imagine who had not tried it, and if the plan is carried out and a system of rearing young queens annually, there need be no danger of having worn out old queens in an apiary.

Drones Still in Hives.

A sure sign of queenlessness at this season is when drones are still observed in the hive. They may usually be seen on the wing when the sun is shining brightly during the middle of the day. If it is dull they will not leave the hive, and if the hive is queenless, or the colony is headed by an old decrepit queen (which is sometimes the case), the bees will not kill off the drones. If by chance only a solitary drone is observed to enter a hive it should at once be examined, and in all probability will be found queenless. It is useless leaving them with a view to introducing a queen next spring. If it is a strong colony it is not too late to introduce another queen. But the plan I prefer at this season is to unite them to one of the weaker stocks in the apiary. This must be carefully done, or fighting will take place. If the bees are brushed from the combs of each stock into an empty skep, and sprinkled with flour, both colonies being shaken together, and thrown down on a sheet in front of the frame hive in which they are to remain, a puff or two of smoke will cause them to run in together without the loss of a single bee.—An English Bee-keeper.

TO CORRESPONDENTS

*** All correspondence relating to editorial matters should, until further notice, be directed to "The Editor," **8, Rose Hill Road, Wandsworth, London, S.W.**, and **NOT** to Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Seedling Clove Carnations (*J. C. A.*).—The flowers sent are rich in colour, double, serrated, and fragrant. The fact that the seed you obtained from a pod of the old Clove, and which was sown in February, producing plants which have flowered so well and so soon, suggests fertilisation with pollen of the Margaret Carnations, though you do not mention having these in the garden. The plum-coloured variety is particularly attractive.

Asparagus "Fern" (*A. F. G.*).—There is usually a good demand for what is known as "Asparagus Fern," in Covent Garden and other flower markets, and those who have a considerable supply no doubt find the culture profitable. Your 7 acres is not the right kind for producing what is required in decorations, the species the most in demand for the purpose being Asparagus plumosus nanus, a native of South Africa, and grown under glass in this country. It would do no particular harm to cut some of the slender tops off your plants now, but as we fear they would realise a very small amount of money it might be as well to leave them where they are.

Do Tomtits attack Peas? (*E. H. O.*).—Yes, occasionally, instances of which have been from time to time recorded in our columns, and we have verified the statements by observing the habits of the birds. Commonly, however, sparrows are the chief delinquents. Hawfinches occasionally clear the Peas off wholesale, and so also do jays, but these are seldom seen at work, as they feed very early, and we have known wood pigeons clear off the entire crop of late Peas. There are two effective plans of preserving the Peas—namely, killing the birds and netting the rows so that no small birds can enter. Pilchard netting is required for excluding tomtits. We have used petroleum emulsion with good effect, as a solution of it makes the pods distasteful to the birds, the plants being syringed on a fine day so as to get the stuff to dry on the pods. This repeated occasionally proved effective.

Leather-jacket Grubs (*Evesham Gardener*).—We are unable to say, in the absence of specimen, what your man discovered. The female Tipula oleracea lays small black shining eggs, always in little heaps on or just within the soil, commonly about this time of the year, and the larvæ appear from them in the course of a few days if the eggs are laid early in the autumn, but commonly they do not appear until spring, at the earliest about February, generally at the beginning of May. The grubs feed during the summer, usually ending in late June to the beginning of August, but some much later, then pass into chrysalis or pupa form, and appear as daddy longlegs in late summer and autumn. The grubs are found from experience to be best acted upon by nitrate of soda, 2½ cwt. per acre, 1¾ lb. per rod. It stupefies them, and they ultimately die, whilst the crop thus relieved is accelerated in growth.

Diseased Chrysanthemum Shoot (*A. G.*).—The bud "taken" in the shoot you sent is "deaf,' and the upper leaves blackened, and to some extent clammy. On making a vertical section of the bud we found the interior quite hollow, brown, and dead, and under the microscope came first upon an egg, and then a (so-called perfect) four-legged creature, the Chrysanthemum bud gall mite (Phytoptus chrysanthemi, *Abbey*), discovered in 1893, which was for the first time illustrated and described in the *Journal of Horticulture*, September 28th, 1893, page 291. There was also the complete animal, but in skin form only, but it is the one named that devours the heart of the Chrysanthemum bud and causes it to be "deaf" or "blind.' In the leaves, where black and covered with sticky substance, eelworm (Tylenchus devastratrix) was found, and may be a consequence of the attack by the mite. Burn such shoots, and another season dust occasionally with tobacco powder, or spray with petroleum emulsion solution at intervals.

Plantains on a Lawn (*H. G. A.*).—The surest method of exterminating Plantains is to dig them up with small forks that are made for the purpose, obtainable from nurserymen and horticultural sundriesmen. Another way is by applying oil of vitriol from a stone blacking bottle, with wire round the neck for carrying it in one hand, having in the other a stick, with several notches cut round the end to the extent of an inch or so. By plunging this stick in the vitriol the notches hold enough for killing a plant or two by pressing the point of the stick exactly in the centre of each. It must not touch boots, clothes, hands, or be drawn along the grass, as the vitriol will burn everything it touches. In a few days after doctoring the withered Plantains may be swept up, and if the "stuff" has been properly applied the roots will be burnt out. Relative to the books you had better mention about the cost you do not wish to exceed, sending a stamped directed envelope for reply. You give no information as to the particular kind of information needed, but only ask for the "best" books, and these would cost several pounds. Please repeat the subjects, as your letter, now it is answered, cannot be preserved.

Names of Fruits.—*Notice.*—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. *In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing.* The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. *They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state.* (*E. H.*).—Your Apple has been compared with a few thousand others at the Crystal Palace Show, and examined by all the leading fruit experts who assembled there. It is regarded as a local seedling, and never had a generally recognised name, and is not thought worthy of a very good one. (*T. R. B.*).—1, Marie Louise; 2, Braddick's Nonpareil; 3, New Hawthornden. (*Amateur*).—The Apple is a local seedling, which probably has never had a name. The Pear is Catillac. (*A. G.*).—1, Gansel's Bergamot; 2, Souvenir du Congrès; 3, Duchesse d'Angoulême; 4, Beurré de Capiaumont. (*F. B.*).—1, Mère de Ménage; 2, Gloria Mundi; 3, Lord Derby; 4, Sandringham; 5, The Queen, 6, Warner's King. (*B. N. N.*).—1, Comte de Lamy; 2, Seckle; 3, Wadhurst Pippin; 4, Gascoyne's Scarlet Seedling. (*J. B.*).—Possibly an abnormal fruit of Tower of Glamis. (*J. R.*).—The smaller specimen is a typical Warner's King, and the larger, though differing, is probably the same variety. (*M. E.*).—1, Beurré de Capiaumont; 2, Souvenir du Congrès; 3, Beurré Superfin; 4, Williams' Bon Chrêtien; 5, Pitmaston Duchess.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*R. F.*).—The plant appears to be the Virginian Poke Weed (Phytolacca decandra), which is found in several gardens, and no doubt birds distribute the seeds. (*M. M.*).—1, Aster amellus bessarabicus; 2, A. acris; 3, A. cricoides. (*R. P. J.*).—1, Chrysanthemum latifolium; 2, Pyrethrum uliginosum; 3, Chrysanthemum maximum; 4, Helianthus rigidus. (*B. P.*).—1, Rudbeckia nitida; 2, Helenium autumnale. (*M. A.*).—All your specimens were quite dead through being in the post over Sunday. (*J. G.*). Through packing in wood wool all the nature had been drawn from the specimens, and they could not be named. The Pear is not recognised.

OUR FRIEND IN VELVET.

How does the dictionary classify or describe "vermin?" "All sorts of small animals or insects which are destructive to grain or other produce; noxious persons." Now, this is clear and definite at any rate, and it remains with us to look closely at evidence before us ere we can truly designate our little friend the mole as vermin.

Set a report afloat, and see how difficult it is to stop that report; nay, indeed, how impossible it is to prevent its being magnified, distorted, and twisted till at length little of the original matter remains. The old proverb about the dog and his bad name and ultimate end is as true to-day as in the days of Æsop. Once let the idea get thoroughly established in men's minds that a certain animal or plant is obnoxious or detrimental to their welfare in the smallest degree, not the most circumstantial evidence will convince them to the contrary. So few people cultivate habits of close observance—we are so ready to take all on trust, and ready to swear by (not on) the printed book. We have a beautiful faith, but it is the faith of ignorance, not assurance.

It is almost a wonder that among an agricultural population we do not find more students of natural history or science—perhaps there are these students, but modesty keeps them from lifting up their voice in the street, or at the corners of the market place. The agriculturist has the grandest of opportunities, he is for ever out and about with Nature in all her moods, and might, if he had the observant eye, daily learn some lesson of her gracious teaching.

We have looked through much evidence with regard to the manners and habits of the mole, and the conclusion we have arrived at is this—that the harm they do is so infinitesimal as to be quite overbalanced by their good properties, and to our mind there is a very great question as to whether they do any harm at all. The indictment against them is that in grass or freshly tilled land they throw up unsightly hillocks. These hillocks consist of fine earth, and on grass they cannot but be productive of much good, the earth, if spread with a spade, forming a most excellent natural top-dressing.

Now about the freshly sown field. Possibly a few seeds are displaced (not eaten); and displaced, why? Because the mole was in pursuit of some insect or grub which might have been injurious to the growing crop. On land where moles are found exists a most capital system of surface drainage. The mole constructs its runs for nothing; no other drainer works for us on the same terms.

This little mammal is furnished with most wonderful digging and excavating tools. The forepaws or hands are furnished with long and strong claws; the bones of the forearm are short, and the muscles most powerful. When the mole is not in a hurry it flattens and compresses the superfluous earth worked out of its passages; it is only when in active pursuit of prey that it forms the well-known molehills. Now as to its food supply. It is not a big animal, and yet it requires a large amount of food. Then, too, its family has to be provided for, and five or six young moles do not live upon air.

Dr. Jessop, writing from a part of Norfolk where the mole has been practically exterminated, draws a sad picture of the destruction of vegetation by myriads of beetles, which have practically destroyed the Strawberry beds. Earthworms appear to be its common food, and a gentleman who kept a mole in confinement is of opinion that it could eat its own weight of worms in a day. Not only will it do this, but it has been ascertained that before the beginning of winter the mole prepares a larder by making a cavity in a bed of clay and filling this cavity with worms, evidently considering the time when frost will have made the earth too hard for tunnelling.

Here is the bill of fare for three days of a mole kept in confinement:—"Three or four dozen earthworms, a large frog, a quantity of raw beef, the body of one turkey poult and part of another, and a big black slug or two." Another naturalist, Macgillivray, states that the mole devours quantities of grubs, and Frank Buckland records the fact that in Hampshire where the moles had been on grass land, that land was after much more luxuriant, and that when all the grubs were eaten in one part, the moles then migrated to fresh fields and pastures new.

Then again, as every seed time comes round we hear of the ravages of the wireworm, and the papers teem with practical suggestions for getting rid of this plague. We have destroyed the balance of Nature, and now have to provide costly measures to remedy the evil. The mole is only too ready and willing to devour wireworms if they can get the chance, and they will do it much more effectually than we can.

Mr. Trevor Ballye gives us some interesting notes on the habits of moles, especially in July and August, when these industrious little creatures come above ground to search for white slugs and the larvæ of the crane fly (daddy longlegs); these larvæ are perhaps better known by the name of "leather jackets." In another place he speaks of moles making a raid on the larvæ of the cockchafer, which are particularly destructive to the roots of vegetation.

Sir Herbert Maxwell records a case in Somersetshire where on some grass land moles had been exterminated, and where, in consequence, the fields were simply covered by craneflies, the larvæ of which feed on the young grass roots. The larval stage of these insects lasts for three years, so it does not require a great stretch of imagination to picture the actual harm done. See a molehill among young growing Turnips, it is a sure sign not of malicious damage by the mole, but of the certain presence of wireworm, and if the only thing in favour of mole was this fancy for wireworm, this fact alone should save its life.

[Ought not there, then, to be the best of crops where moles are prevalent? Is it so?]

WORK ON THE HOME FARM.

If proper use is being made of the fine autumn weather we are enjoying, there should be little work left amongst fallows for next summer. We never knew a better time for autumn work, and trust we may have a continuance until all the Potatoes are stored; we have lively recollections, and not very pleasant ones, of last year's muddy fields.

The second early Potatoes are all marketed, and supplies are now being drawn from later kinds. Few of the latter are ready to take up, and there is so much second growth, that the quality can hardly be anything but second class; what they require is fine weather to ripen them off slowly and naturally. At any rate we cannot hurry them out of the land, except for immediate consumption, for it is very doubtful whether they would keep.

There is plenty of work for every spare hand at this season; watercourses are still low, and many large ditches have little water in them, so there would be a good opportunity for cleansing or deepening. In cleaning ditches or making new ones, it should always be remembered to make the bottom narrow enough, with the sides shelving to the desired width; they will then keep themselves clear for a much longer period than with a flat bottom, on the same principle as does a sanitary pipe.

We have lately had the opportunity of inspecting the farming of two neighbouring counties. Harvest was all gathered in, but the stackyards are not very full; pastures green, but very short. Turnips are in every case deficient, and we never saw a decent crop; some fields have hardly a root in them. This is a serious state of things, and must have an effect on prices of store stock.

Since commencing these notes rain has begun to fall heavily: this is disappointing for autumn work; nothing will benefit except Turnips, which require rain frequently in their present unhealthy condition.

REMARKS.

26th.—Overcast till 10 a.m.; bright sunshine after, and clear night.
27th.—Thick fog early; the sun shining through from 9 a.m., but slight fog or haze all day.
28th.—Overcast early; rainy from 9 a.m. to 10.30, followed by faint sunshine; overcast afternoon.
29th.—Foggy early, with spots of rain; fair morning; sunny afternoon; heavy thunderstorm with much lightning from 7.30 to 10 p.m.
30th.—Fair day, with faint sunshine in morning.
1st.—Overcast till 11 a.m., then sun, and cloudy afternoon.
2nd.—Fair early; generally sunny from 10 a.m. to 2 p.m., and cloudy after.
Temperature much the same, but the nights warmer.—G. J. SYMONS.

Journal of Horticulture.

THURSDAY, OCTOBER 14, 1897.

THE JOURNAL OF HORTICULTURE *can be obtained from the Office,* 171, *Fleet St., London, post free for a Quarter,* 3/9. **Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.**

ROSE ANALYSIS, 1886-1897.

THE arrival of the Rose catalogues from the nurseries reminds me that the time has arrived when this analysis should be issued, for any information bearing on the selection of varieties ought to be in the hands of the selectors as early in October as possible, so that their orders for new plants may be forwarded in good time. The advantage of sending in early orders is twofold—the likelihood of securing better plants, and the certainty of their being despatched directly they are ready for removal from their quarters in the nurseries. The latter consideration is one of the greatest importance, as it allows of Roses being planted under the most favourable conditions, and particularly will this be the case should November happen to prove mild, and the soil be in good working condition. A few days lost at this important season through delay in ordering the plants will often have considerable influence on their next year's growth. Besides this, in a seasonable autumn the soil becomes gradually colder and colder as November advances, and when December has been reached one never knows how soon a frost may come, which will suspend all planting operations for weeks together.

Before proceeding to consider the relative positions of the Roses mentioned in the tables, it may be advisable to say a word or two, as usual, respecting the last exhibition of the National Rose Society, and the character of the past Rose season, both of which have more or less influence upon the tabulated results for the present year. The Crystal Palace Show was held this year on July 2nd, which is one of the earliest dates possible for that exhibition, at all events, as these dates are at present arranged. It was a very extensive show, indeed the largest the Society has ever held, the number of "exhibition" Roses amounting to 7200. The flowering season at the time the exhibition took place was, as in the preceding year, remarkably early as compared with that in an average year. The weather at the end of June had been unusually hot, but the Show day itself proved only moderately warm, and as there was an absence of sunshine the flowers retained their freshness throughout the exhibition.

It is remarkable to notice in scanning the performances of the different H.P.'s, as set out in a table I have drawn up for this and other purposes of comparison, how certain seasons favour, in a more or less marked degree, certain varieties. Some sorts are much more affected in this way than others—for instance, Mrs. John Laing has consistently taken the lead of all the other Hybrid Perpetuals at

HYBRID PERPETUALS AND HYBRID TEAS.

* New varieties, the positions of which are dependent on their records for the 1897 show only.

every one of the last six exhibitions, whereas the number of Charles Lefebvres has varied considerably during the same period. Nevertheless, the fact remains that all Roses have their particular seasons or record years. For example, at the exhibition of 1892 the following varieties were more numerously staged than at any of the other eleven shows. The numbers after the names of the Roses show the maximum number of times that each of the varieties mentioned was staged in the prize stands at any exhibition. La France (49), A. K. Williams (40), Charles Lefebvre (32), Etienne Levet (34), Ferdinand de Lesseps (21), and Le Havre (20). In 1893 records were established for Alfred Colomb (42), Earl of Dufferin (28), Dupuy Jamain (24), Fisher Holmes (24), Duke of Wellington (24), Camille Bernardin (28), and Reynolds Hole (19). In 1894 Marie Baumann (40), Merveille de Lyon (36), Baroness Rothschild (28), and Jeannie Dickson (14). In 1895 Her Majesty (41), Heinrich Schultheis (23), Duchess of Bedford (17), Duchesse de Morny (16), and Charles Darwin (13). In 1896 Gustave Piganeau (29) was the only prominent Rose which thus distinguished itself. Coming now to our last National Show, we find Mrs. John Laing (56), which for the fifth year in succession heads the list of H.P.'s, was oftener staged than on any previous occasion. In fact, out of nearly seventy prize stands at that exhibition open to Hybrid Perpetuals, there were only eleven which had not in them a specimen of this remarkable Rose. It was also a record year for Susanne Marie Rodocanachi (34), Horace Vernet (32), and Victor Hugo (19)—three Roses unrivalled in their respective colours; and Prince Arthur (22). Among other established kinds which were also unusually well shown in 1897 may be mentioned Ulrich Brunner, A. K. Williams (which has only twice before been as often exhibited), Her Majesty, Gustave Piganeau, François Michelon, Margaret Dickson, Marchioness of Dufferin, and Xavier Olibo. On the contrary, either the season, or the date of the show in respect to it, proved disastrous to such prime favourites as Madame G. Luizet, Marie Baumann, Alfred Colomb, Charles Lefebvre, Merveille de Lyon, Etienne Levet, Baroness Rothschild, and many others.

New Roses, those sent out less than six years ago, were not greatly in evidence at the last exhibition, as compared with the number to be seen at the preceding show. It is, however, gratifying to notice that out of the eight new kinds represented six occupy better positions than in the previous analysis. To begin with Duke of Fife, the only 1892 variety, a bright but somewhat thin sport from Etienne Levet. It is needless to say that this is not one of the aspiring varieties referred to, as it has fallen since last year from No. 40 to No. 55. 1893 is credited with Marchioness of Londonderry, Captain Hayward, and Marquise Litta. Of these the first named continues to hold the forward place accorded to it in the previous analysis, and stands at the head of all the white, or nearly white, H.P.'s. Captain Hayward, notwithstanding the warmth of the summer, has risen from No. 30 to No. 28. Marquise Litta (No. 44), unlike all the other new Roses mentioned here, is of foreign origin, and no doubt on this account for the first time appears in the table at all. Last year it was shown in only three prize stands, this year it was set up in twelve. It is such a good grower, so distinct in colour, and in other respects so promising, that it is likely to be much more frequently staged another season. Mrs. R. G. Sharman-Crawford (No. 12), which came out first in 1894, gains two places, an excellent performance considering the high position it previously occupied. Marchioness of Downshire, of the same year, rises from No. 51 to No. 26. The season of 1895 is credited with two new sorts. The first of these, Mrs. W. J. Grant, is a superb Rose, which in the last analysis was to be found only at No. 63, but now with one grand stride rises to No. 28, and is pretty certain when more largely grown to occupy one of the leading places in the table. The other 1895 variety, Helen Keller, has also made capital progress, rising from No. 51 to No. 33.

As rosarians are never tired of discussing the relative merits and

TEAS AND NOISETTES.

32	5·0	5	Comtesse Panisse	1877	Nabonnand	Flesh, tinted coppery rose

* A new variety, the position of which is dependent on its record for the 1897 show only.

demerits of different varieties, it may be of interest if I continue the remarks I made last year on some of the more prominent Roses in the table of H.P.'s. These remarks, it may be remembered, were principally based upon the performances of the various established kinds as revealed in the table of comparative results for the twelve years previously referred to. The first Rose to notice is that grand dark crimson H.P. Horace Vernet. Although more than thirty years old, it has never before been as popular with exhibitors as at the present time. In fact, where five blooms of it were on an average staged at the first six exhibitions of the period covered by the analysis, more than seven were set up at the last six. It is generally stated to be a Rose of but very moderate growth as a cut-back, but in my own garden it makes a taller and more vigorous plant than most of the other Hybrid Perpetuals growing under precisely the same conditions. That sturdy variety, Etienne Levet, retains its position well, and would stand higher in the list were it a little more constant. Mr. Foster Melliar, in his "Book of the Rose," aptly describes the willowy Earl of Dufferin as "a Rose for exhibition but not for garden culture." It is decidedly late in flowering, and very dependable in forward summers, its records for the last five shows being remarkably good and consistent. The variety which follows is also late flowering, and one of the oldest in the table. Considering how many pink Roses have appeared since Baroness Rothschild was sent out in 1867, it is surprising to see how well it still holds its own. In fact, in none other of the twelve years was it as numerously shown as in 1894 and 1896. Dupuy Jamain, another old favourite, which although at no individual show largely staged, still retains a good place, owing to its wonderful consisteney.

We next come to a Rose of very distinct growth, François Michelon. This year it appeared in something like its old form, but is evidently declining in favour. Louis Van Houtte, which follows, is a fine dark H.P., but unlike its rival, Horace Vernet, it has been rather less frequently shown in recent years than formerly. Prince Arthur, the next on the list, has proved itself singularly constant, its records for eleven of the twelve exhibitions ranging only between sixteen and twenty-two. Fisher Holmes, a very old variety, appears to be in greater request than ever, having been staged nearly half as often again in the latter as in the former half of the twelve years. Although small for an exhibition Rose, Duke of Wellington also maintains its position remarkably well. Victor Hugo, another small Rose, but indispensable on account of its glowing crimson tints, was very slow in making its mark; indeed, only at the last five exhibitions has it obtained anything like a footing. Ferdinand de Lesseps, with which is included Maurice Bernardin, has been less frequently shown at the last four exhibitions than previously. Marie Verdier, although so distinct in colour from any other Rose in this section, is decidedly less popular than formerly. I will only now refer to one other variety, and that the oldest on the list, our old friend Général Jacqueminot. It requires a cool season, and consequently its records are somewhat erratic. Nevertheless, considering its thinness and antiquity, it may be said to hold a surprisingly good position at No. 35.

Catherine Mermet still remains the champion Tea. The Bride gains ground upon it a little year by year, but at the present rate of increase it will be a very long time before it reaches the highest rung of the T. and N. ladder. Innocente Pirola has succeeded in passing Comtesse de Nadaillac, while Souvenir d'un Ami takes the place of Souvenir d'Elise Vardon. The most remarkable advance is, however, that shown by Madame Cusin, which rises from No. 13 to No. 9. At no previous show has this fine variety been as numerously represented as it was this year. In fact, it appeared in more stands than any other Rose in this section. Madame de Watteville was also unusually well shown, and gains two places in consequence.

On the other hand, those two beautiful Teas, Comtesse de Nadaillac and Souvenir d'Elise Vardon, have, as previously indicated, each fallen a step. The latter variety has never before been as sparsely shown as at the last three exhibitions. The snow-white Niphetos is another Rose which appeared in comparatively few stands this year, while Ernest Metz falls from No. 9 to No. 12.

The only Tea Roses on the table less than seven years old are Maman Cochet, Medea, Bridesmaid, and Muriel Grahame. All are valuable additions to this section, and curiously enough two of them sports from the leading flower—Catherine Mermet. Medea, although first sent out in 1891, has, as it were, sprung suddenly into notoriety, for at none of the previous shows was it staged in prize stands more than six times, whereas this year there were only nine other Teas more frequently exhibited. Of the two 1893 varieties, Maman Cochet still retains the prominent position it secured last year at No. 5, while Bridesmaid remains as before, near the bottom of the list. Muriel Grahame, although only distributed in 1896, was shown this year in seven different stands, and gained the silver medal for the best bloom of any Tea exhibited by an amateur, not only at the Crystal Palace, but also at the N.R.S. Show at Norwich.

I have again to express my best thanks to those brother rosarians who so kindly assisted me in taking down the names of the Roses in the prize stands at the last Crystal Palace Exhibition.

The Newer Roses Audit.

For those new Roses whose places in the analysis depend so much upon the character of one or two seasons, whether favourable or unfavourable to their respective requirements, this audit has been instituted. Each of the following voters were requested to place a mark against the six varieties they considered best in the list of H.P.'s and H.T.'s on the circular sent them, and a similar mark against the best three of the five Teas. *Amateurs.*—Mr. J. Bateman, Mr. W. Boyes, Dr. S. P. Budd, Mr. P. G. C. Burnand, Rev. F. R. Burnside, Rev. A. Foster-Melliar, Mr. C. J. Grahame, Mr. H. P. Landon, Mr. R. H. Langton, Mr. E. B. Lindsell, Mr. H. V. Machin, Mr. O. G. Orpen, Rev. J. H. Pemberton, Mr. A. Slaughter, and Mr. A. Tate. *Nurserymen.*—Messrs. G. Burch, J. Burrell, C. E. Cant, Frank Cant, W. F. Cooling, A. Dickson, R. Harkness, W. J. Jefferies, H. Merrywcather, G. Mount, G. Paul, A. Piper, A. E. Prince, W. D. Prior, and A. Turner.

Hybrid Perpetuals and Hybrid Teas.

Position in Audit.		Total No. of Votes.	Votes by Amateurs.	Votes by Nurserymen.
1	Mrs. R. G. Sharman-Crawford ...	27	14	13
1	Mrs. W. J. Grant (H.T.)	27	13	14
3	Captain Hayward	22	10	12
4	Marchioness of Londonderry	20	9	11
5	Helen Keller	19	8	11
6	Marquise Litta (H.T.)	16	7	9
7	Duke of Fife	7	4	3
7	Marchioness of Downshire	7	6	1
7	Tom Wood	7	3	4
10	Clio	6	1	5
11	Charlotte Gillemot (H.T.).....	5	4	1
12	Marjorie (H.T.)	2	0	2
13	Mrs. Harkness ..... / Paul's Early Blush	2	1	1
	Teas.			
1	Maman Cochet	29	15	14
2	Muriel Grahame	25	12	13
3	Bridesmaid	21	11	10
4	Medea	10	7	3
5	Golden Gate	5	0	5

Another year, if the voters can be prevailed upon, as some have this year on their own account done, to place the new Roses in the two sections in their order of merit, much more satisfactory and valuable results would be obtained. But even as at present arranged, the voting is so consistent that there will be little difficulty in picking out the varieties considered the best.

Roses for General Cultivation.

The following select lists have been revised with the usual care, but the alterations made from year to year are necessarily slight. As in the previous selection, all the established sorts named in each list have been placed in what I regard as their order of merit, considering the purposes for which they are intended. This arrangement is intended to assist those who require only a moderate number of varieties or

plants. The sorts marked with an asterisk are of recent introduction, and are arranged alphabetically.

EXHIBITION ROSES. — HYBRID PERPETUALS. — *Light Coloured Varieties.*—Mrs. John Laing, Madame Gabriel Luizet, Marie Finger, Merveille de Lyon, Baroness Rothschild, *Clio, *Marchioness of Londonderry, and *Mrs. R. G. Sharman-Crawford. *Medium Reds*—Ulrich Brunner, Dupuy Jamain, Comtesse d'Oxford, Susanne Marie Rodocanachi, Camille Bernardin, Heinrich Schultheis, and *Helen Keller. *Reds.*—Fisher Holmes, Général Jacqueminot, Marie Baumann, Alfred Colomb, Mauriee Bernardin, Dr. Andry, Duke of Edinburgh, Earl of Pembroke, Victor Hugo, and *Captain Hayward. *Dark Varieties*—Prince Arthur, Charles Lefebvre, Duke of Wellington, Prince Camille de Rohan, Earl of Dufferin, Louis Van Houtte, and Duke of Connaught.

HYBRID TEAS.—La France, Viscountess Folkestone, Captain Christy, Caroline Testout, Grace Darling, Kaiserin Augusta Victoria, White Lady, *Marquise Litta, and *Mrs. W. J. Grant.

TEAS AND NOISETTES.—Marie Van Houtte, Madame Lambard, Hon. Edith Gifford, Caroline Kuster, Scuvenir de S. A. Prince, Souvenir d'un Ami, Innocente Pirola, Anna Olivier, Madame Hoste, Rubens, Francisca Krüger, Jules Finger, *Corinna, and *Maman Cochet.

BOURBON.—Mrs. Paul.

GARDEN ROSES.—SUMMER FLOWERING.—*Provence.*—Common or Cabbage. *Moss.*—Common or Old. *Damask.*—Rosa Mundi. *Hybrid China.*—Charles Lawson (climbing). *Austrian Briar.*—Austrian Copper. *Hybrid Sweet Briars.*—Janet's Pride, *Jeannie Deans, and *Lady Penzance. *Ayrshire.*—Bennett's Seedling or Thoresbyana (climbing). *Evergreen.* — Félicité Perpétue (climbing). *Climbing Polyantha.* — Claire Jacquier, Grandiflora, and *Turner's Crimson Rambler. AUTUMN FLOWERING.—*Hybrid Teas.*—Augustine Guinoisseau, Bardou Job, Camoens, Gloire Lyonnaise, Gustave Regis, and *Madame Abel Chatenay. *China.*—Old Blush or Common Monthly, Laurette Messimy, *Madame Eugène Resal, and *Queen Mab. *Teas and Noisettes.*—Gloire de Dijon (climbing), W. A. Richardson (climbing), L'Idéal, Rêve d'Or (climbing), *Beauté Inconstante, *Madame Pierre Cochet, *Souvenir de Catherine Guillot, and *Souvenir de Madame Eugène Verdier. *Bourbon.*—Souvenir de la Malmaison. *Polyantha.*—Madame Anna Maria de Montravel, Gloire des Polyantha, Perle d'Or, and *Georges Pernet. *Japanese.*—Alba, Madame Georges Bruant, and *Fimbriata. *Perpetual Scotch.*—Stanwell Perpetual. Two new climbing Roses should be also included, *Alister Stella Gray (N.) and *Paul's Carmine Pillar (single flowered).—E. M., *Berkhamsted.*

A WELSH VINEYARD.

WE are sending you to-day by parcel post a box containing three bunches of Grapes picked from the Vines at Swanbridge. They are typical samples of the crop there this year, which is very great—greater than any previous year. As you see, the berries are remarkably well coloured, but not nearly so sweet or palatable as they usually are in good seasons, the reason of which is undoubtedly the protracted cold weather during August and the early part of September. You will notice they are exceedingly juicy, and are in excellent condition for wine-making, and my father is sanguine of a vintage of twenty-five or thirty hogsheads this year of a wine that will not depreciate the high reputation already acquired by the Welsh wines.

The vineyard at Swanbridge has been a veritable picture for the last fortnight. The rows and rows of Vines in long unbroken lines, with their strong, healthy green foliage here and there relieved with high colours of autumn tints, and each set off with thick clusters of jet black Grapes, has created a scenic effect, the uniqueness of which in these parts has been exemplified by the numbers of people who have taken advantage of the fine autumn weather we are now experiencing to visit it, and see for themselves a real vineyard. To cyclists of both sexes it has proved a great attraction.

"La vendange" commenced on the 8th inst., and the first Grapes were put through the égrappoir in the afternoon, one large vat being already full of fermenting viniferous matter. It will be Wednesday or Thursday next before all the Grapes are gathered in. Unfortunately, though Castel Coch promised well in the beginning of the season, the mildew completely reversed the state of things, and the result is nearly a failure. During the last few years mildew seems to have claimed this vineyard peculiarly as "its own," for notwithstanding frequent periodical applications of the Bordeaux mixture and up-to-date continental usages for combatting it, it still remains the unconquered foe of the Castel Coch Vines. The old Vines are the worst afflicted, the younger ones appearing able to throw off the malady. Happily the vineyard at Swanbridge is exempt from this evil.

I am desired to send you these short notes, as there is so much upon the subject at present in the daily papers, and father is inundated with questions from persons all over the country who are interested in horticulture requesting information upon the present year's results, which will be known in due time.—HUGH A. PETTIGREW.

[The bunches received are small, densely packed clusters, about half a pound in weight, of Grapes as black as Sloes, and ⅝ inch in diameter. They would not take a prize for flavour, but are capable of making excellent wine. The variety is presumably the Gammi Noir.]

HARDY FLOWER NOTES.

ONE of the charms of a well-furnished garden of hardy flowers is the variety it presents as the year goes on. Sameness and monotony there need not be. From the dawn of spring until frost sets its seal upon the earth a constant succession of flowers will come to give joy to their owner. Thus it is that as October breaks upon us we are still in possession of many flowers. Spring Leucoiums may yet be long of coming, but their fairy-like sister the Autumn Snowflake still hangs its pendent bells from its chocolate coloured stalks. The grandeur of the spring Crocuses is as yet hidden 'neath black earth, but those which are yielded by the shortening day have equal if less voluptuous charms. The Tulip has yet to wait awhile before it opens its cup to the sunshine of May, but the statelier Gladiolus has not yet deserted us, and still gives us more than passing pleasure. There are yet many flowers in bloom ready to smile upon us until bitter winds come to steal away our treasures for a time. Of some of these it is our duty now to tell.

One of the most satisfactory of the autumn flowers is that distinct-looking Helenium which is, unhappily, under a cloud so far as its nomenclature is concerned. This is the one first called H. grandicephalum striatum, and which the Rev. C. Wolley-Dod considers may be H. nudiflorum. I am still inclined to think that it may be as well until we learn more about it to retain another name —*i.e.*, H. autumnale striatum. This is, however, by the way, and my purpose now is not to elaborate this point, but again, as has been done before, to draw attention to the plant's distinctness and decorative value. It is now fairly well known to many, but would find more acceptance did it always present the deeper colouring it assumes in some gardens. Although the size of the flowers is to some extent reduced, I am of opinion that the colour of this Helenium is intensified by being grown on a comparatively poor soil instead of a richer one. The same treatment has also the effect of reducing the height of the plant—a decided advantage in many gardens.

Still effective are the Kniphofias, and they are all the more so from the distinct appearance they present in the garden, where there are at this season Composites in great profusion. As I have remarked before, beautiful as are some of the newer yellow-flowered hybrids, we have less of these this season than of the scarlet varieties. The beauty of some of these yellow varieties, such as Lachesis, can hardly be gainsaid, but we do not desire to see the garden overwhelmed with this colour at any time. To some it is no recommendation to a plant to say that it comes into flower early and blooms on for a long season. They say they prefer something of more short lived beauty, which will not pall upon them before it ceases to bloom for the season.

To these—and they are comparatively few—Kniphofia Rooperi cannot be recommended, but to those who like a plant which will yield them a long succession of flowers it will be found worthy of its room in the garden. There are some with larger and more brilliantly coloured spikes, but there is none of more prolonged blooming habit. It comes into bloom often in June and continues until frost comes. In mild localities, such as some parts of Ireland, I am told that this Torch Lily is rarely out of bloom. With the usual precautions K. Rooperi is hardy, and it will not be long until we have to take these. Tying the leaves together to form a cone so as to throw the rain off the crown will be found beneficial, and this ought to be supplemented with a little broken or dry litter. K. Rooperi has been introduced for more than forty years. It comes from British Caffraria. Although it is said to grow only 2 feet high it really considerably exceeds that height.

Last year in going through a nursery having an almost unique collection of hardy flowers, I saw among the Asters one bearing the name of "F. W. Burbidge." I observed to my guide "that this should be a good one." His reply was, "and it *is* a good one." The result was that a plant was booked, and this is now in bloom. It is

not always that our gardening friends have their names attached to plants whose merits entitle them to this distinction—and one so distinguished as the curator of Trinity College Gardens deserves that his name should be given to no mediocre flower. One would like to say that this Michaelmas Daisy does full justice to the name it bears. That were hard to do; but it is, notwithstanding, a plant of exceptional merit, large as is the number of superior Starworts. The catalogue description is—"the best of all; colour soft rosy blue; flowers very large, produced in the utmost profusion—A1." Without committing oneself to the opinion that it is "the best of all," one may with safety say that Aster F. W. Burbidge is a beautiful and useful variety. The bright colour of the unopened flowers is a noticeable feature of the plant, while its habit is excellent, being graceful and of medium height.

Among the other flowers still in bloom the Crocuses, as usual at this season, must come in for notice. The pretty C. iridiflorus, the effective C. speciosus, the pleasing C. zonatus, with C. pulchellus, and others, are in bloom. I do not know why it is, but C. zonatus seems to possess a special attraction for the slugs, which crop off the flowers almost as they appear, although frequent search is made for the destroyers. On the other hand C. speciosus is left almost severely alone. Of the autumn flowering Croci none of the white forms is better than those of C. cancellatus. This is a variable species in regard to colouring, as it varies from white to light purple. In its more Western habitats it is generally white, the Eastern forms being blue or purple. For convenience bulb dealers appear to recognise the white form with purple at the base as being the typical one, and for purposes of convenience this may be accepted for gardening purposes. This white form of C. cancellatus is of good substance with flowers of a fair size, although coming short in this respect of the white Dutch Crocuses so familiar in our gardens in spring. It is truly a pretty little flower, deserving a sunny and sheltered place where the autumn sunshine, cool though it is, may strike full upon its flowers. There are several varieties, and any may be safely grown so far as their beauty is concerned.

With flowers such as these, even when October has come, we find much to admire, and others bear them company still. Modest little Cyclamens rise only a little above the earth, which before long will be hidden from sight by the pretty, marbled leaves of this Neapolitan Sowbread. Charming little flowers are these, yearly growing finer here, and never losing favour in our eyes. There are yet dwarf Campanulas, too, mostly in flower for the second time. C. Portenschlagiana is one of these, and it gives a bright tone to the places in which it grows. Nowhere does it look better than hiding some crevice in the rock garden, where its purple-blue flowers and fresh, green leaves seem in keeping with their surroundings. Late as is the season, one might particularise for long. When Sunflowers, Heleniums, Michaelmas Daisies, St. John's Worts, Meadow Saffrons are still with us there is no want of a text on which to found a homily. Their glory is dimmed but not obliterated. It shines still to give us cheer as the garden's year fast runs its course.—S. Arnott.

THE TRUTH ABOUT FRUIT TREES.

I think there has been enough of word-chopping over this subject, and as my literary opponent appears to think so too, we agree with each other on one point at least, if not on more, and doubtless several readers will agree with us both. Let us come to practical points. We neither want a mass of crowded shoots on the one hand, nor gaunt scraggy branches, however straight, on the other. Those are the two extremes, of which there are too many examples, and the truth lies, as usual, between the two.

In the cultivation of trained trees we have, or ought to have, two objects in view—1, the uniform covering of desired space; and 2, the production of fruit. The first condition means that there must be just sufficient branches, the leaves of which can develop fully for covering the space and no more; the second condition means that the wood must be of the most fruitful character. Neither exhausted wood on the one hand, nor young shoots or branches too closely crowded in on the other, can possibly be the most fruitful; but give the young wood a chance, then will it far surpass much that is old, too old, on many trees in the production of fruit. This I have proved over and over again, and most observant gardeners of equal or longer experience must of necessity know the truth about the matter as well as I do.

When I see this truth exemplified, no matter where, of space uniformly covered with productive branches, the sight not only affords me pleasure, but I am apt to think a narration of it, however brief, may be suggestive and instructive, because there are always men who err, regardless of age, in one or the other of the two extremes aforementioned. Besides, I think really good work, by whomsoever accomplished, is worthy of recognition. I was therefore, for those reasons, glad to be able to fulfil a long-standing promise to visit Mr. Kean. In the fine trees he has produced (page 311) I found confirmation of what I believe to be the truth, namely, that the too long and rigid adherence to a particular system of pruning and training, after that system, no matter how satisfactory it was once, has ceased to be so, is a mistake, and that intelligent departures are followed by better results.

Let me cite an instructive case. On page 333 appears an excellent portrait of that accomplished fruit grower, Mr. George Woodward. I happen to be able to tell something of the trees which produce the grand fruit he exhibits—I knew them well when I was a garden lad. The gardens at Barham Court were then a noted home for fruit trees trained in almost every conceivable form, and in no place have I seen trees trained with greater accuracy. I visited the gardens again little more than a year ago. What did I find? The old order had passed away. Many of the trained trees, as such, had reached the limit of their productiveness, and Mr. Woodward, like the practical man he is, perceived it and changed his methods.

Horizontal cordons which had formerly been trained to look so neat beside the edges of the walks had been allowed to grow more in the form of an elongated bush than a cordon. Apples and Pears growing on arches, instead of being spurred in closely each year as in the old days, had short-jointed shoots extending above and around the trellis in all directions, and these were weighted down by grand fruits. I was interested in the trees, and inquired closely about them. Then Mr. Woodward willingly informed me that the fruit obtained under the close pruning system was not abundant enough to be satisfactory, hence the change in their management and the grand results. Special attention was given to keeping the shoots thinly disposed.

The truth about fruit trees is that years ago, and even yet, many trees were, and still are, prevented from bearing a good crop of fruit by over-pruning and training. Observant men began to see the mistake of adhering to the custom of cutting all summer growths back to wood that could not bear, while some of that removed, if rationally treated, would have produced good crops of excellent fruit. This in practice was found to be so. The benefits resulting from the change were made known in conference room, lecture hall, and through the press, and things began to improve. May still further progress be made in the important work of fruit production is the wish and object of—H. D.

[A most commendable wish and desire; and when controversy draws forth such an excellent article as this, from one of the best of gardeners, it cannot be said to be a failure. Not only mere "word-chopping," but much of the thoughtless knife-hacking of many fruit trees might with advantage cease.]

VEGETABLES FOR HOME AND EXHIBITION.

Leeks and Celery.

Not only is the Leek amongst the most useful of vegetables, but it is peculiarly interesting, inasmuch as it is to Wales what the Rose is to England, the Thistle to Scotland, and the Shamrock to the Emerald Isle. Striking by contrast, therefore, are the parts it plays on the one hand as the popular emblem of a country teeming with history, on the other as an important attribute to the contents of a kitchen garden; and though the latter may appear to be less romantic, it is from this standpoint of utility that gardeners have to look at it. For exhibition only the best samples are suitable, and as these can generally be obtained through careful attention to detail in cultivation, the returns given are well worth the trouble expended.

Where the vegetable is required in quantity successional sowings are advised, the first to take place in March and the second in the following month. Though Leeks will flourish fairly well in almost any soil and locality a rich rooting medium is conducive to size, and for whatever purpose they are required, large, sound, silvery-stemmed specimens are always appreciated. A great mistake often made is that of leaving the young plants too long in the seed bed before transplanting, with the result that they become drawn and spindling, with the roots all matted together. As soon as the seedlings are about 6 inches high they should be carefully transplanted in well prepared ground, allowing 10 inches apart if large stems are required, and about 6 inches if this is not the chief consideration. A dibbler is the best implement for planting, and the roots should be inserted as deep as the base of the leaves, only lightly placing the soil in round them. Some growers always plant in trenches the same as Celery, and on light soil the method is a good one; but where the medium is of a retentive nature this is not necessary if a little earth is drawn up to the stems as they increase in size. Water must be liberally applied in dry weather, and the surface soil kept constantly stirred with a hoe.

It is not advisable to leave the best roots out during the winter,

but, on the other hand, to take them up on the appearance of severe weather and store them in moist sand as recommended for tap-rooted vegetables, under which treatment they will keep for some time. Though large roots are in requisition for exhibition purposes, those of moderate size are better for keeping, and therefore careful management in thinning and transplanting is necessary. In this operation lies the only secret in successful Leek culture; weak, half-starved looking specimens are the result of neglect, and sound healthy white stems, prized alike in the kitchen and on the exhibition table, are the reward of prompt and careful attention. Variety among Leeks is somewhat limited, and there is perhaps none to surpass the Lyon for exhibition.

If Celery is not grown well it is better not to attempt its cultivation at all, as the result is disappointing in all respects. The best samples that can be obtained for home use are also the best for exhibition, though, unfortunately, one often sees the first prize card placed on gigantic sticks which have only size to recommend them, as in flavour they are invariably tough, and with very little of that sweet nutty taste which makes Celery palatable. Sound, well blanched sticks of moderate size are always the best to eat, and this is the end that all cultivators should aim at. Thousands of miserable specimens are sold in London every year bearing the name of Celery. The name, however, is a libel, as they will not bear comparison with the well-grown produce that is produced in many gentlemen's gardens. Generally speaking, the metropolis is supplied with excellent vegetables, but Celery is an exception, and it is questionable whether hundreds of people who are in the habit of purchasing so-called Celery every week, know what the real article is like. Quantity seems to be the aim with most market growers, and for some reason or other the crop does not get that close attention to detail that is absolutely necessary to produce really wholesome and thoroughly palatable produce.

To produce good Celery a few simple rules should be rigidly followed. In the first place there must be no check in the growth, or this causes the plants to "bolt" or run into flower, and the result is uselessness. The plants must be kept free from suckers or side growths, or the nourishment requisite to full development is divided into the various channels, and no heart is formed. Then, again, it is a mistake to sow too early, as planting is then often delayed till that check has taken place, which the cultivator should endeavour to avoid. In most gardens early Celery is required either for table use or the summer exhibitions, and for this purpose seeds should be sown of an early white variety at the end of February or the beginning of March. Sow thinly in a propagating box in a temperature ranging from 60° to 65°. When the seedlings are large enough for removal they may be pricked off into other boxes and grown close to the glass in a moist atmosphere or else be transplanted in a hotbed frame. With the advent of genial weather, the plants must be gradually hardened by leaving off the lights, and if finally transplanted in well-prepared trenches an early and useful supply may be obtained.

The middle of March is early enough for sowing for the main supply, and it is a good plan to prick out a portion of the seedlings in a frame that has been used for raising early vegetables, where they can be kept close if necessary, and the remainder will come on for finally planting a little later if pricked out in sheltered position outdoors. If a little manure from a spent Mushroom bed is worked beneath the surface of the soil when pricking out, it will be found that the plants will lift with excellent balls, and suffer little from the removal. It is well when pricking out the tiny plants to imagine what they will be like by the time they have to be removed to the trench, and dispose them accordingly. If grown too closely together in the nursery bed the roots naturally get matted with each other, and a check at the time of planting through excessive damage to these fibres is the result.—GROWER AND JUDGE.

SAXIFRAGA BITERNATA.

DESPITE its utility and great beauty this species, which blooms in the spring, is seldom met with, though it cannot be considered a new plant. It belongs to the section Nephrophyllum, of which the best known representative is the common S. granulata. All the species composing this section are deciduous, and of a more or less bulbiferous habit. S. biternata has, as will be seen from the accompanying engraving (fig. 54), very distinct biternate leaves, which form fine tufts of bright green colour. The flowers are pure white, comparatively large, and are borne on short stalks. Like the other members of the section, S. biternata prefers a damp shady position in sandy peaty soil. It is a native of Spain and Algeria.

If "J. Harrison" desire more information relative to this or any plant we shall be pleased to give it to him, but he must address his letters to 8, Rose Hill Road, Wandsworth, as directed, and *not* to 171, Fleet Street, as formerly.

THE CONQUEST OF CANKER.

WHAT is canker that we should make so fearsome a bogey of it, as Mr. Abbey seems inclined to do? Is it some dread thing that has to be exorcised with yard-long lists of vile chemicals? Let me come honestly and promptly to one pregnant admission: it is the most destructive pest that our gardens and orchards know, and it is far from my intention to throw ridicule or contumely on the patient investigations which our good friend has made, doubtless at the cost of many an hour which others who have reached his years think well to spend in repose. True it is, beyond any reasonable doubt, that no

FIG. 54.—SAXIFRAGA BITERNATA.

other hand of the old practical school could have ferreted out such minuteness of detail, drawn such a series of admirable sketches, and then explained (on page 292) the whole thing in so clear a way that the veriest tyro could understand. But—for a big but there is—there is a tendency to elevate canker into a thing so formidable that only those who can put their hands on a whole laboratory of chemicals, *plus* magnifying power of first 10, then 40, and next a jump up to 400, can feel that they have a chance of coping with it.

We all know about the tablet which is going to sustain an army, but all of us do not know that as a result of some extraordinarily complete and sagacious calculations, a pilule was compounded which, going into one tiny corner of a soldier's knapsack, was yet enough to keep him in brisk marching order, and so full of fight, that the very sight of him was calculated to frighten off a whole regiment. Yes, it was tried, that pilule, the expectant inventor rubbing his hands as he watched its disappearance; but alas! Tommy Atkins was ravenously demanding a beafsteak within a quarter of an hour afterwards, and my Lords have, therefore, decided to keep for the present to the old style of fare.

There is nothing to prevent the amateur scientist from playing pranks with Nature if it please him to do so, and equally there is nothing to stand in the way of his devising a variety of strange and mysterious concoctions if it conduce to his amusement, but plain men who have made canker one of the studies of their lives will need no assurance that their case is not hopeless, even if the sulphates and the sulphides and the carbonates are beyond their reach. What you have got to do is first of all to recognise accomplished facts, and then you are in a fair way of being able to dispense with lens, microscope, and every "ate" and "ide" there is in the catalogue for conquering canker.

Our canker remedy never fails. I am going to pit it boldly against all the finicking or chemically imposing and memory torturing remedies which Mr. Abbey or anyone else can bring forward, and I am simply going to ask that it shall have a fair trial. It is based on Nature – on helping the tree to throw off the blighting influence which has fastened upon it in preference to attempting to destroy the blight itself. You may use barrels of wash, and squirt to your heart's content, or discontent, and you can never effect radical cures unless you do something else as well, and that is to take under your care the vital force for good which is working deep down in the heart of every plant and tree, ever striving to throw off evil, and rise to better things.

Mr. Abbey talks of the efforts made by the tree to drive out the intruder, resulting in the latter becoming firmly seated in the tissues until the tree becomes girdled "and then," he significantly adds, "comes the end." No, there is no such finality. I admit that if the girdling becomes complete the tree is doomed, but that is not because the efforts of the tree to force away the disease have resulted in the secure embedding of the latter. It does not matter how firmly and deeply embedded the diseased tissue may be, it is still possible for the tree to be brought back to perfect health. Why, so far is it from being true that the recuperative efforts of the tree have any hastening effect on its own end, that I know of trees which have woven a complete coating of new bark over huge masses of dead wood, and engulfed them for ever. There is no "end" to the tree; on the contrary, it enters on a new lease of life from the time its efforts at exclusion were so successful that it was able to bury the enemy in the pit itself had dug. I could show Mr. Abbey trees in almost every stage of this fierce life struggle, some with huge gaping wounds, over which the new rolls of bark are just beginning to run, others in which the conquering folds have half hidden the malignant or dead matter, and yet others, again, in which but a small slit remains to be seen, by peering through which the last vestiges of the useless wood may be discerned. There are pounds upon pounds of these hard and lifeless lumps within the internal economy of some of the larger trees, and the latter go on as placidly, as comfortably, as fruitfully, as if every ounce of them was wholesome, healthy, growing tissue.

And what is the secret? Just manure and tar. The former is not the miserable stuff which comes down from the London vestries; but rich invigorating matter from stable and cowhouse, where the animals have good food to eat and sweet air to breathe. The tar is plain Stockholm tar. The manure is put on in the form of a liberal coating, reaching out to the uttermost spread of the branches, and the tar is brushed on after as much as possible of the diseased parts have been cut away. It is a plain process from beginning to end, but commend me to it in preference to all the chemical washes which the wit of man could devise.

By attempting to kill fungi and insects we are engaged in thwarting Nature; by arming a tree against them we are working in harmony with her own beneficent designs.—W. Pea.

HARMFUL AND HARMLESS GARDEN MOTHS.—9.

About this time, when Ivy is putting forth its green bloom, the honey of which invites a crowd of insects both by day and night, those who are cutting its sprays for autumn decoration may come upon a caterpillar of dingy grey, looking like a little bit of stick, but marked on each side with a yellow line. It may have taken to the Ivy for food, but more probably it has sheltered there to await another spring, hybernating, as do several kindred species. We may have made its acquaintance in September, when the caterpillar now and then feeds on the leaves of Roses, and it has been found on Plum, Birch, and Oak, but is not an abundant insect. The moth emerges in June or July, and has been called the willow beauty, also Boarmia gemmaria, the popular name implying that it has been bred from Willow, and that somebody thought it handsome. The colours are not bright, certainly—black, brown, and grey; yet the markings are elegant if examined. Some specimens occur nearly black, as if in mourning. Another in the genus that I have seen about the gardens of Surrey is the mottled beauty (B. repandata), which has really a good title to its name, though a variable moth usually lighter in colour, the waved markings being upon a ground of grey and orange. We notice it on a summer evening, but I have observed it flying by day. During May the caterpillar, which is light yellow dotted with black, may be taken on Plum, Birch, or Hawthorn in gardens. On Wimbledon Common it eats the Bramble and Ling; about the North the Bilberry is frequently selected for food.

The waved umber (Hemmerophila abruptaria) we mostly see in a position of repose, spreading its wings on a paling or outside a house. It is a moth so distinctive with its pretty lines and spots, that, though the colours are not bright, we cannot well forget it when once recognised. There is nothing particularly "abrupt" about this insect, but it is a moth we associate with the arrival of spring. Later in the season its caterpillar is one of the many that are feeders upon the Rose; we know it by its being a "looper," dark brown, having a white ring behind the head, and I could hardly expect a gardener to spare its life, or dismiss it to seek other food. It is stated also to eat Privet and Lilac, and is a familiar species of London suburbs. Around the metropolitan district, but earlier on the wing than the preceding, the small engrailed moth (Tephrosia crepuscularia) visits on April evenings the flowers of beds and borders. It is found in most English counties, also in Ireland. The name was given because part of the pattern on the wings seemed to resemble what is called an engrailment in heraldry, wavy lines of black crossing the grey ground colour. A variety of food suits the brown caterpillars, Fir, Oak, Elm, Poplar, Birch, and other trees or shrubs. Some years there is a second brood of moths, succeeded by autumn caterpillars.

We have all seen some of the emerald moths about gardens, all of delicate texture, slight bodied, their green tints apt speedily to fade, hence their beauty is not exhibited in a cabinet of moths, and a rough wind often damages them soon after emergence. One of the smaller species is Geometra vernaria; the wings are of an exquisite green, crossed by two white lines, head and thorax rather a paler green. It is a July insect, at least so far as I have observed, though it would appear from its name to have been noticed in the spring. The caterpillar feeds on the wild Clematis and on the cultivated species. Like the moth in colour, the caterpillar resting on the leaves is not easily seen; its head is curiously notched on the crown. Another of the emeralds, common amongst the gardens of Middlesex and Surrey, where the caterpillar lives on the Hawthorn hedges, but is seldom seen, is Hemithea strigata, also a summer species. The wings are of a darker green, less liable to fade, and have the margins scalloped. Smallest of the emeralds is the little Iodis lactearia, greenish white, marked with white lines, which often flits past us in the June twilight; the caterpillar is slender and brownish, its food being the leaves of Birch.

The entomologist is familiar with the small group of moths that are called the "waves," of moderate size, most of them showing waved lines on the wings, and the gardener cannot fail to notice some of them from time to time, since they usually repose by day on walls, trunks of trees, and occasionally on leaves of plants, not being easily startled. None of the species is hurtful to cultivated plants, though a few may pass their lives within garden precincts. We may just pick out three that are to be met nearly everywhere. Of the diminutive species we have a good example in the pretty moth oddly named the small fan foot, or Acidalia bisetata, having a central black spot on each wing, and irregular dark brown lines upon greyish brown. Its caterpillar feeds low down amongst wayside or garden weeds, such as the Dandelion and the Knotgrass. Larger, and perhaps the most conspicuous of the wave moths, is the ribbon wave, a mid-summer species, abundant throughout Britain. Its appearance in gardens is accounted for by the fact that the caterpillar lives upon a variety of hedgerow plants, such as Avens, Bird's Foot Trefoil, Chickweed, also sometimes in the low shoots of Willow. This caterpillar is rough like shagreen, being covered with numerous tiny warts, and is dark brown. We at once recognise A. aversata in its winged form by the broad band or ribbon which crosses the middle of all the wings, and which is of an ochreous colour, the rest of the surface being a dull yellow. Then the common white wave, Cabera pusaria, we seldom fail to see every year in gardens near parks and shrubberies, for there seems to be a succession of these moths from June to August. In colour the caterpillar varies much, being grey, brown, or green. It rests on a twig generally, with the body pressed close, and the head also flattened, hence it is not easy to detect.

We pass now to a destructive species, which is the cause of annoyance and loss some seasons, the moth taking its English name from the Currant, but in Latin Abraxas grossulariata, and the Gooseberry, I think, is preferred to either the Red or Black Currant by the caterpillars; the ornamental species is seldom eaten by them. Probably its original food was the Blackthorn, and it has been taken on the Peach and Almond. All of us know the moth and caterpillar too well, both somewhat alike in their colour, if not exactly in markings. The moth has usually numerous black spots scattered over the whitish yellow surface, but very curious varieties occur, some almost entirely

dark, and others pale, with only a few black streaks. It is not a difficult moth to catch, and especially as it often flies by day, the females going from leaf to leaf, depositing but one egg on each. As the eggs cannot be easily found, some have recommended the removal of the leaves from the bushes about the beginning of September, these being burnt. Probably, however, before that date most of the young caterpillars would be hatched; still by this expedient many would be removed, but perhaps this stripping might be hurtful to the bushes. Certain it is that they do little mischief during the autumn; it is after hybernation they are voracious, especially damaging to Gooseberries. About their winter habits Newman remarks, "Each young caterpillar selects a Gooseberry leaf, and makes it fast to its twig by numerous silken cords, to prevent its falling when dehiscence takes place; in the cradle thus fabricated the caterpillar sleeps as the sailor does in his hammock, storms and winds are matters of indifference to him."

This is true so far, but part of the brood hide away amongst dead leaves on the ground, in empty flower-pots, and odd corners; during the winter months many of these caterpillars might be removed by a little search. In the spring they may be shaken off the twigs without difficulty, since when alarmed they swing down from their food, running out a thread of silk as they do so; the agitation given to the bushes should be gentle, otherwise the caterpillars are scattered about, and do not fall into the article held to receive them. Dusting the bushes early in the morning with any of the usual dressings while the dew is on them is effective, and syringing. But for my part, I have always felt there are several objections to the employment of washes containing Paris green or similar poisonous compounds. It is principally where pruning has been neglected that the Gooseberry caterpillar harbours.—ENTOMOLOGIST.

IMPROVING MUSCAT VINES.

I AM sending a bunch of Muscats, cut from a Vine thirty to forty years old. Six years since it was lifted. Previous to that it grew indifferently. It is now carrying at least 30 lbs. of Grapes, or thirteen bunches. Two years come January next we built a new house over the old Vines. Previously the borders were outside. I persuaded my employer to have a border inside as well, and to make the house 3 feet wider. This did away with the front wall, against which in passing through the Vine stems were injured.

We had then to throw 4 feet of soil back for the bricklayers to work. We picked the soil carefully from among the roots; still many got broken. They were matted up at first, but these soon had to be taken off, being in the way of the workmen. Practically the roots were exposed from the middle of January until the middle of March. The house is built on pillars, 4 feet apart. Plates are fixed on these, and screwed together for the house to rest on. In building the pillars some roots which we had managed to save had to be cut out of the way. The house is 90 feet long, with one division.

The inside border was concreted and well drained. The soil from the front was returned, and any mould that was lying about, a few loads of turf from a drain that was being cut, abundance of burnt earth and mortar rubbish were thrown in to compose the inside border. This was rammed as firmly as possible. Last year the Vines started very weakly, but gained strength by the autumn. We pruned to plump buds; they started strongly in the spring of this year, the berries were small till stoning, but swelled rapidly afterwards. The border inside had a slight sprinkling of Thomson's manure and a good dressing with the contents of earth closets (the soil used in these being taken from the burnt refuse heap) and watered in with liquid manure at pruning time, but only that part of the border containing the roots. In addition we gave two light mulchings with litter and another sprinkling with closet manure through the summer, always washing in with weak liquid manure from the home farm, or made from pigeon manure when the farm tank is low. The outside border was dressed with basic slag in February, otherwise it was treated the same as the inside one. I think there is plenty of iron in the soil; in lifting the fruit trees we had to use picks and crowbars to get through it. Next month we rake off all mulching, loosen the soil, and give a good dressing of lime, pointing it in. I have read the Journal since I started gardening, and well remember the article by "Single Handed," When, Why, and How We Manure Our Vines.—S. B. O.

[The Muscat Grapes improved by the methods above described, as well as a bunch of Black Hamburghs from forty-years-old Vines, also renovated, are in all respects—size, colour, and quality—fit for the table of a prince. There were none to equal them at the Crystal Palace Show. Some leaves sent are remarkable for substance and colour. The sound substantial literary fare of "S. B. O." is more satisfying than are columns of pen flourishings by ancient and modern controversialists.]

CATTLEYA DOWIANA.

THIS beautiful Cattleya is yearly becoming more popular, its richly tinted blossoms making it everywhere a favourite. In habit it does not differ much from the rest of the labiata section, but the flowers are quite distinct. In the variety aurea the lip is more highly coloured than that of the type, and this is perhaps the better known form, though there are several sub-varieties more or less distinct. C. Dowiana is a native of Costa Rica, and the first living plants of it that arrived in this country were brought by a Capt. Dow, to whom it was dedicated.

This was in or about 1864, but many years before this the Polish collector, M. Warscewicz, discovered it and sent it home, but the plants died either on the journey or soon after their arrival. The variety was found by Wallis, and since then has been imported very frequently by English and continental nurserymen. Its habitat is not the same as that of the type, but possibly both are found, as well as improved forms, in the same locality. At all events they turn up among the same consignments, so presumably the area is a fairly large one, and each exists in greater or less numbers in every part of it.

The cultivation of all of them is similar. They like plenty of warmth and light when the growth is active, and a decided resting period. It is, in fact, one of the easiest of all kinds to grow in a suitable house, but it is not always as free blooming as one might wish. The plants have the bad habit of starting into growth from the base almost as soon as the young pseudo-bulb is formed, and without the requisite rest the growth does not seem capable of producing a flower, though the pseudo-bulb preceding it was healthy and vigorous enough. To build up a strong, yet at the same time a hard and solid bulb, then, will be the grower's first care.

This he cannot do in a heavily shaded house, or in one always reeking with moisture, without the necessary ventilation, but given the latter in reason, so as to always provide a constant supply of air about the foliage and bulbs, then C. aurea can do with plenty of both heat and moisture. The plants should be suspended within a foot of the glass if possible, and in such a position that the drip from the rafters cannot find its way to the plant. The screw hooks so often fixed to these are about the worst possible arrangement; a brass or pointed iron rod, running the entire length of the house, and screwed to each rafter, being far preferable.

As to compost, good peat fibre and clean sphagnum moss will do admirably, and large pots are unnecessary. If these are large enough to show a margin of about a couple of inches around the plant they will do, or shallow teak baskets nearly filled with drainage suit the plants perfectly. C. Dowiana and its varieties are rather given to damping at various stages of growth, but especially when the pseudo-bulb is about half developed. In the earlier stages this is probably caused by cold water coming in contact with the tender growths, or a larger supply of moisture than is required.

But later on there is often a glutinous exudation from the plant that prevents the scales parting freely from the underlying stems, and this leads to mischief. The flower sheaths, too, are often quite stuck to the leaf with it, and need the application of the budding knife haft to separate them. It appears to be a provision of Nature against the insects that prey upon the plant, but is not required under cultivation, and should be removed by sponging with clean warm water. Newly imported plants, and others in their second or third year, appear to be more subject to it than older plants that have been a longer period under cultivation.

The plants usually arrive in fair condition, and are not difficult to establish. I have not infrequently potted these and C. gigas exactly as received, except that the plants were well examined for cockroaches and other insects, and afterwards thoroughly sponged. As a general rule, however, it is safe to lay them out for a while on a moist stage in the warmest house at command, and to sprinkle them occasionally with tepid water until they plump up a little. Then they may be potted in small pots and allowed a surfacing of moss only over clean, finely broken crocks.

The compost must be added as the plants begin to root, and they are soon for all practical purposes the same as established plants. Thus it will be seen that they do not differ much from the other labiatas in general requirement, but the advice given respecting their being kept dormant after flowering is important. Only last season I saw a fine collection of aurea that had bloomed profusely, the secondary growth notwithstanding, but this does not alter the fact that they are more satisfactory the other way. During winter 55° is a good minimum temperature for the species, with just sufficient moisture at the root to prevent shrivelling.—H. R. R.

Notes & Gleanings

Weather in London.—During the past week several mornings and evenings have brought indications of the approach of winter. On one occasion six degrees of frost were registered, and has severely crippled Dahlias and other tender plants. On Friday evening it rained heavily for a time, but otherwise the weather has been very pleasant and seasonable.

—— Gardening Appointments. — Mr. William Swan, senior foreman at Drumlanrig, has been appointed gardener and estate manager to Robert Gordon, Esq., Chipstead Place, Sevenoaks, Kent. Mr. Joseph Stoney, for the past fourteen years head gardener to Sir Thomas Earle, Bart., Allerton Tower, Woolton, Lancashire, has been appointed head gardener to the Hon. Frederick G. Wynn, Glynllifon Park, Carnarvon.

—— Presentation to Mr. G. A. Bishop.—On severing his connection with horticultural matters in the neighbourhood of Wolverhampton, Mr. Bishop has become the recipient of a handsome testimonial. Besides a splendid gold watch and chain, an address signed by many influential Wolverhampton men was read at a recent meeting called for the purpose. The Mayor made the presentation and read the address, and Mr. Bishop replied in a suitable manner.

—— The Beddington, Wallington, and Carshalton Horticultural Society.—At the annual meeting of this useful Surrey Society, which was held last week, it was stated that, notwithstanding the many Jubilee claims for subscriptions, as well as counter-attractions, the last year's show resulted in a balance of £53. Mr. G. W. Cummins was re-nominated for Secretary, but he stated that as he had given up his appointment as gardener at The Grange, and that his next one might be many miles away, it was with the greatest regret he had to decline the honour and the position he had held from the commencement of the Society. He acknowledged the great help and encouragement rendered him by Mr. Smee, Dr. Cressy, the Committee, and other officers of the Society, and mentioned that recently he had received a letter from Mr. Halsey (Chairman of the Surrey County Council) complimenting him and the Society on the advance made in cottage garden and allotment cultivation in various parts of the county, which advance dated from the Carshalton Show of 1892. The Chairman and others spoke of the able way in which the management had been conducted, and a vote of thanks was heartily passed, as was also a resolution that an honorarium of 10 guineas be awarded to Mr. Cummins in recognition of his services. Mr. W. T. Toogood (late Assistant Secretary) was then elected Secretary, and Mr. C. F. F. Hutchings Assistant.

—— Fantastic Summer Bedding.—Although we have here in sober Britain sometimes indulged in bedding designs that have been fantastic—indeed, rather ludicrous, and always in abominably bad taste—still may we, without any charge of phariseeism being laid against us, yet take some comfort from the fact that we are not quite so far gone in relation to this matter as some of our horticultural brethren across the Atlantic seem to be. The "Strand Magazine" reproduces in the form of illustrations some of the bedding monstrosities from which, happily, so far we have been saved. It is most earnestly to be hoped that no gardener in Britain will think he has a heaven-sent mission to out-Herod the Americans in efforts of this nature. Washington Park, Chicago, seems to be the *corpus vile* for the designs of the florally insane, and that park is nearly rivalled by the South Park of the same town. Gigantic globes, gates, sundials, elephants, a running ape, a man in a canoe, are some of the floral cranks thus presented. It is a gross libel on gardening to term this sort of thing horticulture. We have in some places at home gone perilously near to the ridiculous in bedding designs, scrolls, Jubilee dates, crowns, and diamonds, but at least some little allowance could be made for so remarkable a celebration as that of the Diamond Jubilee, when, too, so many greater persons than gardeners almost ran mad. We may take it for granted that at home at least the craze for fantastic designs and inscriptions has run itself out. Doubtless by the masses they were immensely admired, and the originators were very proud of them. Still that sort of thing is not only not gardening, but it is pandering to sickly sentiment and depraved taste. We can make our summer bedding most beautiful, and because of that there is all the less reason for making it fantastic.—A. D.

—— A Prolific Marrow.—Three large well-ripened Marrows were last week cut from one plant, weighing respectively 41 lbs., 28 lbs., and 16 lbs., or an aggregate weight of 85 lbs., besides several younger and edible fruits being supported from the same source. The variety was Long Green, and grown by Mr. G. Maxey, gardener at The Toft, Sharnbrook, Beds. Surely this is a creditable achievement. Will some reader kindly say what is the heaviest individual fruit on record?—H. T.

—— Lespedeza Sieboldi.—The warm weather of the last few weeks has been most favourable for this plant, and at present it is flowering very freely. From the tender sub-shrubby nature of the growth a frost or two in September sometimes kills the young wood, and consequently the flowers before they open. In seasons like the present, however, the flowers open well, and make a pretty show during the last fortnight of September and first fortnight of October. In winter the growths die to the ground line, but start away strongly again on the approach of spring. During summer the shoots grow 6 or 7 feet in length, from quite half of which the loose, drooping racemes of rosy purple flowers are produced. The racemes spring from every joint on the upper portion of the stem. The lower ones are often 1½ foot in length, and vary from that length to 3 inches on the upper parts. Although a plant which cannot be relied on to produce a good show of flowers every year, it is worth growing (from the lateness of its flowering) in favoured localities.—D.

—— Antirrhinum Hendersoni.—I send you herewith a few spikes of Antirrhinum Hendersoni. I suppose it will one of these days attain its Jubilee. Perhaps some of your correspondents can tell the date of its introduction. But though so long in cultivation it is still certainly the most distinct, and one without which no collection can be considered complete, while for competition it is quite indispensable.—John Forbes.

[Though we have grown this distinct Carnation-flaked variety for years, commencing some forty years ago, we should not have known it from the specimens, because they arrived practically dead. They were sent to Fleet Street without any packing to keep them fresh and firm, rested there over the Sunday, and perhaps longer, then forwarded to their proper destination, which has been prominently announced in two or three pages for weeks. Flowers in other boxes have arrived much in the same sad state from the same cause—delay through misdirection. We regret it should be so, but have done all we could to prevent such mishaps.]

—— Will of the Late Mr. Alfred Sutton.—Personal estate valued at £114,388 has been left by Mr. Alfred Sutton, J.P., who retired from the firm of Sutton & Sons nine years ago, and who died at Greenlands, Reading, on August 7th, aged seventy-nine years, and of whose will, which bears date January 31st, 1895, the executors are his sons, John and Herbert Sutton, power being reserved to grant probate also to the widow, Mrs. Ellen Sutton, to whom he bequeathed £1000, his furniture and household effects, greenhouse plants, and outdoor effects, and horses and carriages, the use and enjoyment of his freehold house at Reading, and the income during her life of his residuary estate, which, subject to Mrs. Sutton's life interest, he leaves in trust to pay after her death £12,000 in 2¾ per cent. Consols, and £6000 in 3 per cent. Local Loan Stock to each of his three daughters, Alice, Ellen, and Edith, and £7000 each to his five sons, John, Samuel, Francis, Edwin, and Henry, and £10,000 to his son Hugh Reginald. The ultimate residue of the estate is to be in trust in equal shares for his six sons, as having admitted his son Herbert to partnership in his business, he deemed it unnecessary to make further provision for him.—("Morning Post.")

—— Grapes and Asters at Swanmore. — Grapes inside, and Asters out, are two admirable features at Swanmore just now. A late house of mixed Grapes is something to be proud of, especially as the fine crop, which contains many prize bunches, is produced by closely spurred Vines that were planted nearly twenty years ago. They seemed to be embued with all the vigour of robust five-year-olds. It is noteworthy as showing the kind-heartedness of the owner of these Grapes, W. H. Myers, Esq., M.P., that he will neither have them consumed in his own house nor sold. They are set aside for the sick poor, so that these grand Grapes will find their way into the humblest of homes, to soothe and comfort those who need them most. As to the Asters or Michaelmas Daisies, there seems to be quite a museum of them, and as growing in the narrow boundary border in one of the hedge-enclosed sections of the garden, they present a charming, diversified, and most elegant appearance. This is, no doubt, one of the finest collections of these dainty autumn flowers in the kingdom. As Chrysanthemums are not "in," Mr. Molyneux seems to be dividing his affections as equitably as he can between Asters, Grapes, and turkeys, and all are certainly both numerous and fine.—A Caller.

—— NATURE.—On and after Tuesday, October 12th, the editorial and publishing offices of "Nature" will be removed to St. Martin's Street, London, W.C., to which address all communications should be sent.

—— CRYSTAL PALACE SHOW.—In our report of the miscellaneous exhibits at this show we omitted the mention of the stand of Messrs. Wood & Son, Wood Green. This comprised the many horticultural sundries for which the firm is so widely known.

—— LATHYRUS PLATYPHYLLUS ALBUS.—L. latifolia alba of some gardens. This plant makes a fine specimen for the herbaceous border or for dotting singly on lawns, after it gets established; and shows to the best advantage when so treated and staked with ordinary Pea sticks. A specimen here, which flowered a short time since, measured 7 feet in height by 5½ feet in width, and was much admired when covered with its trusses of pure white flowers; it is about six years old. This and the other varieties of L. platyphyllus are sometimes found rambling over low fences, or trained against a wall; but the individual beauty of the plant is not seen to the best advantage in such positions, as it falls about so easily, and the tendrils and growing points do not show themselves. It is readily grown from seed, but only a small percentage comes true; the others revert to the type, which is not so desirable as to colour. The plant flowers the second year from seed, and should be tested in nursery beds before planting in a permanent position, as it is a deep rooting subject, and not easily removed after it gets three or four years old.—W. H. DIVERS, *Belvoir Castle Gardens, Grantham.*

—— EMPSON'S EXHIBITION CARROT.—I send you a sample root of this remarkably fine selection of the intermediate type of Carrot. It is a fair representative of what resulted from a small sowing made last spring in conjunction with various others, both English and French. The trial was on very poor sandy soil at Englefield Green, and was purposed not only to test varieties, but also the capacity of such soil to produce Carrots. The result in all cases was very satisfactory, whether of Early Gem or French Blunt-rooted; Early Nantes, Scarlet Model, or French Half-Long; James' Intermediate or Red Chantenay; New Intermediate, Matchless, or French St. Valery; Long Surrey, and some others. Seed of the Exhibition Carrot was given me for trial by Mr. Empson, with a result quite surpassing any other stocks, the produce being wonderfully fine and good, very clean, and good colour. Evidently it is a very superior selection. The sample root sent has 14 inches of edible flesh, and 2 inches of root points. It is 10½ inches in circumference, about 1½ inch from the crown, and tapers to the point perfectly. Finally, it weighs 1 lb. 13 ozs. It must specially be borne in mind that the soil was very poor sand, but deeply dug. With such a Carrot stock what remarkable possibilities are there in making much of the poor sands of the kingdom immensely productive. Even taking the average roots at 1½ lb. on such soils, and allowing one root per square foot, that would equal some 260 per rod, or a weight of 390 lbs., that is 3½ cwt.; that at per acre would give a bulk of over 27 tons. Surely that would be remunerative.—A. DEAN.

—— UNITED HORTICULTURAL BENEFIT AND PROVIDENT INSTITUTION.—The annual meeting of this popular gardening charity was held on Tuesday evening at the Holborn Restaurant, under the presidency of Mr. H. B. May of Edmonton. The gathering may be termed a distinct success, as there were upwards of 100 members present. After the repast and the health of her Majesty having been drunk, the Chairman proposed the toast of the evening—"The Society." In the course of his remarks he called attention to the fact that the Society had been started by gardeners, and had always been under the control of gardeners. He called the Society a Democratic one, and spoke at length upon its growth, both in membership and in the funds, and was thus enabled to extend its field of labour and become of more and more benefit to gardeners throughout the country. Attention was called to the various funds of this admirable Institution, with special reference to the Convalescent Fund, to which the speaker announced Mr. N. N. Sherwood had sent a donation of 5 guineas. Needless to say that the toast when put was received with acclamation, and with it was coupled the name of Mr. J. Hudson. Than he no one knows better how the Society stands financially, for he has been one of the most industrious of treasurers. His remarks were brief, but teemed with interesting facts relative to the Society, and concluded with an appeal to the gardeners present who were not members to become so then and there. The remainder of the toasts were received with the most unanimous enthusiasm. Amongst the speakers, besides those named, were Messrs. Nathan Cole, George Bunyard, G. J. Ingram, Peter Kay, J. H. Veitch, and C. H. Curtis.

—— PHOTOGRAPHS.—By an inadvertence we did not name the photographers who took the negatives from which our reproductions of Messrs. G. Bunyard and G. Woodward were taken. That of the former was from a photo by Mr. Sawyer of Maidstone, and that of the latter from one by Messrs. Clarke & Co. of the same town.

—— HESSLE GARDENERS' IMPROVEMENT SOCIETY.—The opening meeting of the session was held on Tuesday, October 5th, Mr. Geo. Picker (Hesslewood) in the chair. A paper was read by Mr. Akester, gardener to E. Goddard, Esq., North Ferriby Hall, the subject being "Weather and its Influence on Gardening." The essayist pointed out to what an extent gardening was influenced by winds, frost, sun, and rains; also the manner of forecasting. At the conclusion of the paper questions were invited, and the masterly manner in which the essayist answered them showed that he had the subject fully under control. The syllabus of this session is one of the best the Society has had, and contains essays by many prominent members of the horticultural fraternity. Several new members were enrolled, and altogether this session bids fair to be as successful, both financially and otherwise, as any previous one. A vote of thanks to the essayist and the chairman terminated the meeting. —G. W. G.

—— RUDBECKIA GOLDEN GLOW.—We have been much pleased with this novelty this season, and consider it altogether the finest herbaceous plant for border use sent out in recent years. It is quite distinct from Helianthus multiflorus in that it flowers fully a month earlier and is past when the latter begins. The long-stalked flowers are useful for cutting, and are smooth-stemmed and not so unpleasant to handle as those of the Helianthus. It is also perfectly hardy, a strong point in its favour, as the Helianthus multiflorus cannot be relied upon every year and often winter kills, so that it needs protection to make sure of it. The variety Golden Glow appears to be a form of Rudbeckia laciniata, a rather weedy plant and suitable only for semi-wild situations. This double form is free from the objectionable weediness, and its only fault is in the weakness of its stems, which it is necessary to stake when the flower buds begin to form. Otherwise it is an ideal plant for the border.—E. O. ORPET (in "Garden and Forest").

—— LOUGHBOROUGH GARDENERS' IMPROVEMENT ASSOCIATION.—The first annual report and balance sheet of the Loughborough and District Gardeners' Mutual Improvement Association, which were recently placed before the members, have been sent to us by Mr. D. Roberts, the Hon. Secretary. It is apparent from the Committee's report that an excellent start has been made, and the papers that have been read by competent men at the monthly meetings must have been of material benefit to all who have listened to them. The balance sheet is equally satisfactory, there being a substantial sum on the right side. We congratulate the Society, and trust that the success it has achieved in its first year will be more than maintained in the future. Mr. D. Roberts, Prestwold Gardens, Loughborough, will be glad to furnish particulars to prospective members. In connection with the meeting herewith alluded to an exhibition of fruit was held, and this appears to have been a most creditable affair. Mr. A. H. Pearson, of Chilwell, gave an able lecture on "Fruit Culture."

—— HASSOCKS NURSERY.—An interesting ceremony took place on October 6th, at Messrs. Balchin & Sons' Nurseries, Hassocks. Mr. Richardson, the much-respected manager, was presented with a handsome inscribed timepiece by the employés as a wedding present, also a case of silver spoons, which came as an agreeable surprise to the recipient. We wish him long life and happiness also. Coprosma Baueriana variegata as a decorative plant grown at Hassocks is most valuable. Pyramids 2 feet high and as much through are very striking, with their bright golden and glossy green foliage. Amongst the many novelties in the nursery borders of hardy trees and shrubs which attracted my attention were bushy plants about 2 and 3 feet high and as much through of Coryopteris mastacanthus blooming most profusely. The flowers are a bright azure blue in colour, and are borne in axillary globose heads. It is well worthy the attention of planters. Leschenaultia biloba major grows luxuriantly, as also do Boronias serrulata, megastigma, clatior, and heterophylla. These will doubtless be seen at the Temple Show in quantities in combination with some of the old favourite Ericas.—A. OUTRAM, F.R.H.S., 7, *Moore Park Road, Fulham.*

EDITORIAL NOTICE.—It is particularly desired that all communications, parcels, catalogues, and newspapers intended for the EDITOR, be sent direct to 8, ROSE HILL ROAD, WANDSWORTH, S.W.

THE ROYAL HORTICULTURAL SOCIETY'S COMMITTEES.

Now that the summer flower shows are over, and before the managers of the various horticultural societies throughout the country begin arranging for the future, I think the moment is opportune for bringing under the notice of the horticultural public a matter which is exercising the minds of not a few horticulturists and others. The matter referred to is the composition of the Committee of the Royal Horticultural Society, the members of which are drawn almost, if not exclusively, from London. It will not be urged that London contains the only leading lights in the horticultural world; while, on the other hand, it will be readily admitted that in the provinces are to be found many men who are capable of rendering splendid service in the sphere; and my only object in drawing attention to this question is for the purpose of inducing the executive of the R.H.S. to approach the leading horticultural societies in the country, inviting their co-operation; and this could be effected by the provincial societies nominating, say, a couple of their members, to act upon the Committee of the R.H.S., whereby a thoroughly representative council on horticulture would be secured.—R. V. M.

[This is by no means a new proposition. There are metropolitan horticulturists who agree that, consistently with practical working, the wider the field from which committeemen, who are Fellows of the Society, are drawn the better. Provincial capacity will, no doubt, be admitted unanimously; still there may perhaps be difficulties in the way of carrying out the proposition of our able correspondent, who resides far beyond the metropolitan zone. Can he favour with a list of what he regards as the "leading" horticultural societies of the country?]

HISTORICAL NOTES ON VINES.

From the time that Noah planted his vineyard, every heathen nation seems to have contended for the honour of claiming as its own the distribution of the Vine and its benefits, and deifying him accordingly. The Egyptians, of course, naturally awarded the palm of its discovery and institution to Osiris; the earliest Italians to the great god Saturn; whilst the Greeks insisted that Bacchus, the god of wine, as his title almost implies, was its founder, or at least that he brought the vinous plant from Arabia Felix, commiserating and softening the triumph of his arms by leaving it still as a legacy to the conquered. Still, it will be very naturally asked, Of what country was the Vine originally a native? This question is more easily put than satisfactorily answered. The contention among the cities for being the birthplace of Homer pales into positive insignificance compared with the struggle for supremacy in this great honour amongst the nations of the earth.

Chaptal, who gave great attention to this question, and examined the various claims in a philosophic spirit, makes his award in favour of Asia, that fertile farm and garden whence so many cultivated fruits, vegetables, and even grasses were poured into Europe, as from the home of plenty, together with civilisation and the arts. This is doubtless true, but then Asia is a very large division of the globe. Many give a special preference to Syria. Michaux found the Vine in the woods of Mazanderam, and Olivier beheld it growing in all its attractive beauty of spreading foliage and fruits in the mountains of Koordistan. Pallus saw it near the Black and Caspian Seas, growing without any aid save that of Nature. The Kishmish, a peculiar stoneless variety of the Grape in Eastern lands, is considered by some to be a native of that part of Persia lying on its gulf. In Beloochistan, still farther to the east, the Vine with its tendrils clings to the northern shores of the Arabian Sea. The base of the Parapomisan Mountains is rich with it, blending its clusters with those of the Fig and Olive, and it extends to Cabulistan, where it mingles in friendly proximity with the Apricot and the Peach. The forests of Anatolia and Karamania enshrine it: and Armenia, where Noah may have found it, abounds with the Vine. In a word, there is strong evidence in favour of Persia being its original habitat, and that also is a locality where it has never been neglected, for Khuzzlebush does not seem inclined to lose the privilege of possessing it by lapse of usage, and even beats the European in imbibition, for the wine of that country does not seem to have more effect upon the children of the Sun than upon any vessel, even in their household use.

Sickler traces its gradual immigration and introduction to Egypt and Sicily, and it is more than probable that the Phœnicians introduced its culture into the Grecian Archipelago, Greece, Italy Provence, and Marseilles. The ancient Romans in the days of their political infancy had other sterner and more sober duties to attend to than the cultivation of the Vine, and the libations of milk instead of wine ordered by Romulus for a time necessarily discouraged its cultivation. The nymph Egeria though, certainly it would appear, seems to have given the Emperor Numa Pompilius a hint that a little wine would be a welcome addition to their interviews, for although he forbade the use of wine at funerals, he permitted libations to be made to the gods of well-made wine, thus directing anew popular attention to its cultivation. But wine was certainly scarce for a very long time in Rome, and according to an old story, even in the days of Lucullus only a single draught was allowed at dinner. The time was close at hand, though, when this abstention from wine was to rapidly change into the other direction at the Roman banquets.

This country, there is little doubt, owes the presence of the Vine to the Romans. It does not appear to have been in existence here in the time of Agricola, but the subsequent increased intercourse could hardly fail of introducing it. There is an edict of Probus still extant allowing Gauls and Britons to cultivate the Vine. The Venerable Bede makes mention of several vineyards in his time, and the City of Winchester was long supposed—though in uncritical days it must be allowed—to have received its name from the Vines for which in early times it certainly was famous. The Normans called the Isle of Ely the Isle of Vines, and its Bishop, soon after the Conquest, appears to have received tithes in wine to the amount of several tuns annually from his diocese. Vineyards are frequently mentioned in the Doomsday Book. The Sussex vineyards, near Arundel, the property of the Dukes of Norfolk, from whose produce many pipes of good Burgundy wine were made, shows to what an extent the cultivation attained.

The Marquis of Bute has of late years, on his estate near Cardiff, experimentalised on rather a large scale in the renewed cultivation of the Vine for wine making. It is reported that his wine is excellent, but it does not, I believe, come into the market. In conclusion it may be observed, that although the growth of Vines in the open air can hardly be made profitable for the dessert table, there is a fine industry capable of development for their cultivation for wine making ready to our hands. —Wm. Norman Brown.

CINERARIAS.

When it is grown well this flower is one of the best for the early summer decoration of the greenhouse. When poorly grown it is a most unsatisfactory plant. There is only one other plant that I call to mind that is more subject to attacks of the green fly, and that is the Pelargonium. Put either of these plants in a greenhouse where not a green fly has been seen for weeks, and one need not be in the least surprised to find aphides by the dozen on them inside of two days. Some flowers are improved by doubling, but the Cineraria is not up to date, and I see but little prospect of improvement in this respect.

One of the chief charms of the Cineraria, says a writer in a transatlantic contemporary, consists in the beauty and clearness of its markings, and this beauty disappears when the flower becomes double. At least, such has been my experience with it; but all do not think alike, for a friend of mine prefers the semi-double sorts, he tells me, and he prophesies great things for the future of this flower when single varieties are relegated to the background.

It will be noticed that I have spoken of the Cineraria only as a spring or summer bloomer. It was formerly brought into bloom largely in the winter, but we have so many fine winter flowering plants of easier cultivation, that I have adopted the habit of growing it only for the decoration of the greenhouse at a time when there is a dearth of other flowers. For late spring and early summer flowering I sow seed about January, but for winter bloom it should be sown in July or August. I use shallow boxes filled with light soil, sifting a little soil over the seeds after they are scattered as evenly as possible. Then I press all down with the palm of my hand, and place the boxes in a warm place where they can be kept moist until germination takes place. Never overwater or keep the young plants too warm. If this is done they are pretty sure to damp during the first stages of growth. My experience has been that the Cineraria does better when kept in a moderately cool temperature than in a warm room.

As soon as the young plants have made their second or third set of leaves, put them into small pots, providing drainage that will prevent the mould from retaining more than enough water to keep it moist all through. The best soil I have ever had was composed of turfy matter from old sods and leaf mould, one-third each, and one-third old perfectly decayed manure and sand in equal parts. The soil need not be made fine, but it should not be left loose in the pots. Watch the plants, and as soon as the roots fill the pots they are in, shift to pots one or two sizes larger. Be sure to soak the pots they are put into before using, and see that the drainage is perfect. Too much care cannot be taken about this.

In growing plants through the winter and spring months, great care must be taken not to keep them too close, or they will not be strong and vigorous. Admit air freely on all pleasant days, being careful, however, to keep them out of a draught, and do not give too much water. Heat and moisture induce too rapid and weak a growth where there is little fresh air. The aphis will soon destroy the plant if not interfered with. I find nothing more effective than a solution of sulpho-tobacco soap, and dip the plants in it. This dries on the leaf, and the aphis will not remain. But constant care is necessary, for the pest will soon be back. The plants can be dusted occasionally, while moist, on the lower side of the leaves with tobacco dust, which will adhere for some time.

When flower stalks appear give liquid manure semi-weekly, if it can be had. The Cineraria is not worth keeping after it has given one full crop of flowers. By cutting off the fading flowers some additional ones can be obtained, but they will be greatly inferior, as a general rule, to those first produced.—E. E. R.

A MINIATURE VINE BORDER

(With Results).

On page 281, September 23rd, reference was made to an instance of rapid success in Grape growing. Mr. W. Neild, as then stated, appeared to be no advocate of a large and deep root run for Vines. An intimation was also given that we thought a crop of Grapes could be shown worthy of the name as produced by a Vine in the smallest border on record. Our readers have now an opportunity of judging for themselves, and if a healthier Vine bearing a better crop of Grapes has been seen growing in a quarter of a cubic foot of soil we shall be glad to have particulars of it.

The variety shown is Gros Colman. Others similarly grown were Black Hamburgh, Madresfield Court, and Muscat of Alexandria. The bunches on each Vine were reduced to six, and all of them did equally well except the Muscat of Alexandria, which had a number of seedless berries, which Mr. Neild attributed to the frequent supplies of water necessary to maintain the small quantity of soil in a moist condition.

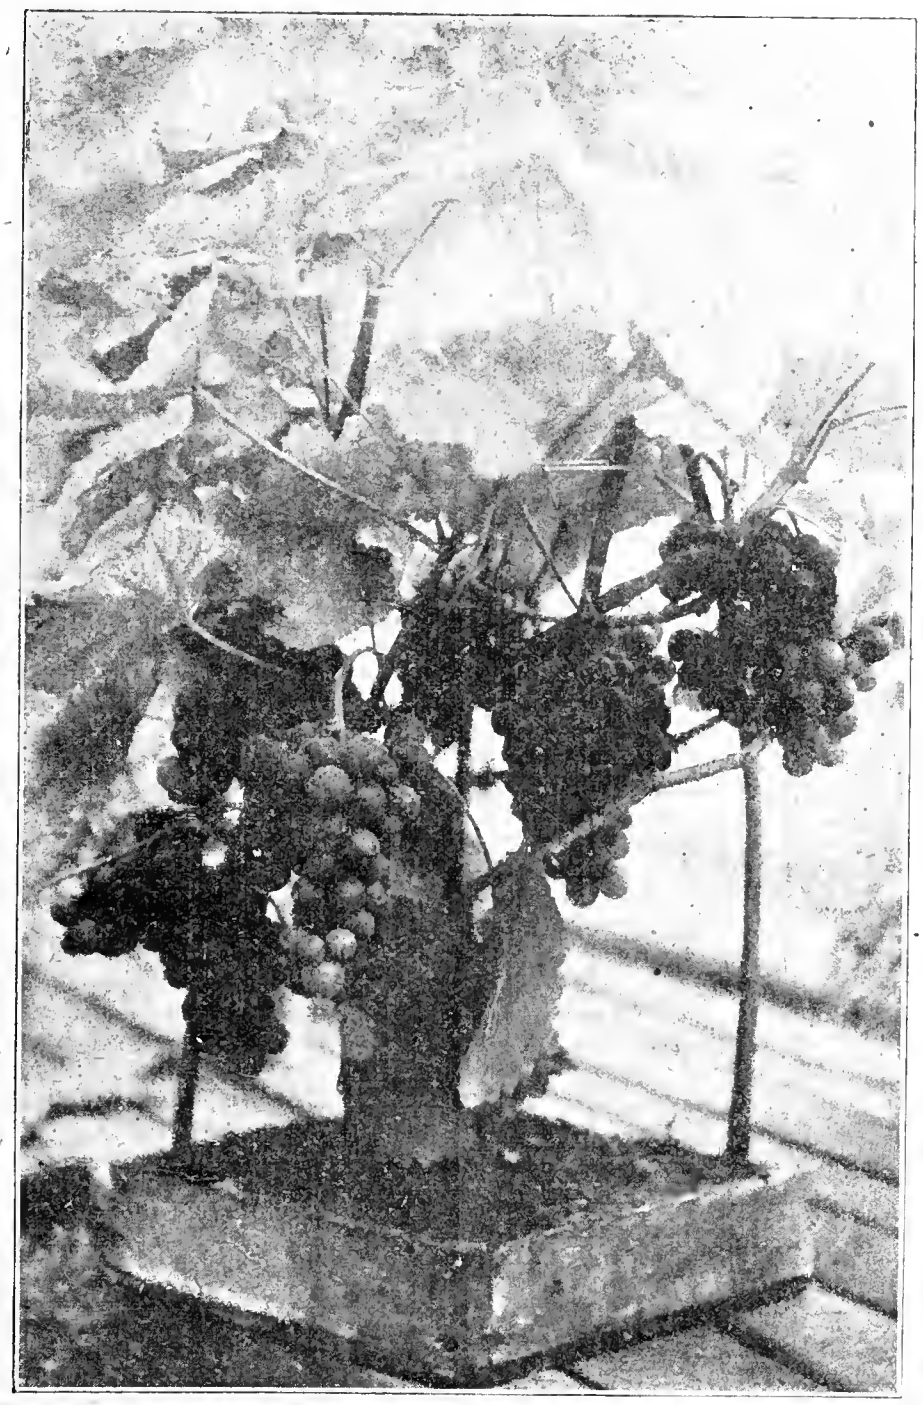

Fig. 55.—A Miniature Vine Border.

In answer to inquiries on one or two points, and for a few particulars, Mr. Neild has favoured with the following reply :—

"The box in which the Vines are growing is exactly a foot square, and 3 inches deep. There has been absolutely nothing done to provide a larger rooting space that what is contained in the box. The box stands on the stage shown in the photo, in the house in which it has been grown from youth to maturity, and the nearest soil is from 3 to 4 feet below the box. No rooting through has ever taken place. My object was not to try to deceive, but to demonstrate what a small quantity of soil a Vine could be fruited in.

"The fruit is colouring well for the variety, and the berries, on an average, measure 3½ inches in circumference. The leaves (of which I send a sample) are large, and have good substance. The compost used for this Vine is similar to that of the Muscat border described on page 281.

"It need scarcely be said that constant attention to the watering and feeding of the plants was requisite. The food employed was good farmyard and stable liquid manure, with an occasional application of nitrate of potash and nitrate of soda."

Mr. Neild with the above information sent us a leaf of the Vine. It was healthy, of good substance, measuring 10½ inches from the top of the upper lobe to the point, and was 9 inches in width. We therefore requested that, if practicable, the different parts of the Vine, also the soil, be accurately weighed. This has been done with the following results :—

Actual Weight of Vine and Fruits.

	lbs.	ozs.
Six bunches of Grapes (Heaviest bunch, 1 lb. 12 ozs.)	7	8
Weight of leaves	0	10½
Weight of stem, laterals, and roots	1	3
	9	5½

The weight of the soil at the time the Vine was removed, and consequently in the ordinary damp state, was found to be exactly 15 lbs. It will thus be perceived that the Vine with its fruit was more than half the weight of the soil in which it grew, and this represents what we call a small Vine border. Only by the best of attention and judgment in watering and feeding could such results have been achieved as represented in the illustration.

A COUNTRY VISITOR'S JOTTINGS.

Horticulturists certainly have abundant change in their occupation, and the varying forces with which they have to contend never permit their employment to become monotonous but even the men who are most devoted to their calling need a change of scene occasionally, the opportunity for which is most fittingly afforded when some great event connected with gardening takes place in the metropolis or the large provincial towns. Gardeners imbued with the true spirit of progress must ever be learners, and whether they are visiting their neighbours or journeying to some distant show, this desire to pick up new ideas, or to place old ones in a fresh light, should be the chief inducement. It is invigorating to the mind also to exchange thoughts and experiences with one's compeers in other districts who may have to work under totally different conditions, and, in consequence, have to modify their practice greatly. It is pleasant to see old friends, and possibly to make new acquaintances, to hear of men steadily progressing on the road to success, and of others who have, by patient perseverance, overcome many difficulties.

So it is that exhibitions become to gardeners something more than a display of produce; they are educational and stimulating, and wise indeed is the employer who, knowing he has a discreet gardener possessing the ambition of excelling in his calling, encourages him in exhibiting, or at least permits him to visit the principal shows, with instructions to "put his expenses in the book.' I have never known such generosity abused; nay, more, in the majority of cases it is repaid with ample interest in increased energy.

The Royal Horticultural Society's Fruit Show at Sydenham attracted large numbers of provincial practitioners to the great Paxtonian Palace, and as one who has not had the opportunity of visiting the metropolis for a long period perhaps may be permitted to jot down a few of the ideas and impressions resulting from my journey. Time was short, but a visit to London without a call at Covent Garden Market would seem strangely incomplete, for even those who have not to contend with the difficulties of selling produce must always find much to interest them in this wonderful emporium. Wonderful it does most assuredly appear on a close acquaintance with the trade there transacted: the enormous quantities of fruit, vegetables, and flowers which pass through it week by week, the numbers of individuals, directly or indirectly, concerned in growing, conveying, and selling its supplies, would furnish an amazing record. His Grace the Duke of Bedford has published one of the most interesting books of the present time in his "Story of a Great Agricultural Estate;" but what a work would be the "History of Covent Garden Market," not as a record of the owner's receipts and expenditure, but as tracing the development of the trade in home and foreign garden produce. It would be rendered, in fact, an epitome of this trade in the whole of Great Britain.

The season has been an unfavourable one for hardy fruits we all know only too well, yet in the market, as far as could be judged by the huge piles of baskets in all directions, both Apples and Pears would seem to be abundant, but the consignments cover a wide area, and therefore yield

but little evidence as to relative abundance or scarcity. As regards the quality, in far too many instances there could, however, be no mistake. Hundreds of baskets of various sizes, bushels, and sieves, in all their complications of varying dimensions and weights, were exposed for sale, displaying unsorted, inferior, bruised, and damaged fruits that could not be regarded without a shudder. Yet this was all British produce. Side by side, in some cases, were neat boxes of Pears or barrels of sound, even Apples, all affording evidence of the greatest care and thought. This was the foreign produce. Is it surprising that the purchaser should prefer the latter? and would it not be wiser to take a lesson from our foreign competitors than to sigh over the difficulties of obtaining good prices, when the contrast under present circumstances is often so much against our own produce? I am aware that certain salesmen will deal in nothing but the best British fruit, properly sorted and packed, wherein they have done great service to many cultivators, who have been forced to learn better methods. But the majority, unfortunately, are not so considerate, or they do not occupy such an independent position that they can refuse business of an unsuitable character.

These matters have been dwelt upon repeatedly in the pages of the Journal, but my excuse for referring to them must be found in the fact that, visiting the greatest market of its kind in the kingdom after a considerable lapse of time, I was much struck with the evidence, so startlingly plain, that British cultivators have yet much to learn besides the art of growing good produce. The contrast, too, was all the more remarkable because within an hour the display of handsome fruits at the Crystal Palace could be reached, and there the credit of our brethren was well maintained, proving yet again what has been so often proved before – namely, that the British cultivator at his best is second to none in the essentials of his art as a grower pure and simple. Why some should fail so deplorably in other respects is consequently the more regrettable.

Perhaps the ladies will teach us a lesson, for now they are entering the ranks as horticulturists we must try to recognise them as friends, and not necessarily as rivals. In what may be termed the "fine arts" department of gardening, wherever taste, neatness, and methodical care will tell, they may be able to teach by force of example what many seem slow to learn. The young gardeners of the future will have a rather agreeable time if they are to be instructed by some of the fascinating feminine horticulturists now being trained at certain establishments. Royal Kew has found employment for some of the ladies, and several, I know, are already in charge of establishments in various parts of the country. There is no question that women and girls can render substantial service in many departments. In the gathering, sorting, and packing of fruits, and such vegetables as Peas and Beans, for instance, many market growers have found their labour more economical and efficient than that of men and boys; and when it comes to flower gathering and packing the females have all the advantage. These thoughts were mostly suggested by two observations on the occasion of my visit. One was that in a certain well-known old Strand restaurant, where hundreds of horticulturists have foregathered at different times to refresh themselves, and where the same men waiters had attended to the wants of their customers from time immemorial, I found the whole system revolutionised. Our ancient waiters had entirely disappeared, their places being taken by "neat-handed Phyllises," and "Hebes." The other matter was the exhibit at the Palace from a horticultural college, where so many ladies have been trained, which displayed a tastefulness and neatness that seemed to be the effects of their presence.

Into the details of the great show I shall not attempt to enter, your able reporters have done that most thoroughly, as they always do; but I shall touch upon a few outside matters that attracted my attention. First, it occurred to me how imperfectly all the fine fruit shown conveyed any idea of the cropping qualities of the different varieties, especially in a season like the present. It is possible by going over a couple of dozen Apple or Pear trees to select twelve extremely fine fruits, even in a bad season; but whether it is worth growing twenty-four trees to get twelve fruits of a pound or a pound and a half, such is a matter of opinion. If one has to supply a large household, or sell the produce, we can soon decide the point. I should like to see a class or classes introduced for the entire produce of a young tree, say from three to six years old; this would convey some valuable information which all would be able to understand and appreciate. The prizes should be substantial, and the crop certified by a witness. In a series of years the Royal Horticultural Society would accumulate a number of facts illustrating the bearing qualities of different varieties under varying conditions that would be of great service.

One notable improvement is observable at these shows, and that is in the arrangement of fruit exhibits for effect. Very tasteful displays are now produced, very different from the formal array of plates which has prevailed for so long at most exhibitions. Mr. Owen Thomas has set several admirable examples in this direction, and his collection at the Palace well showed how the attractions of an exhibition can be increased in this way. Groups of fruiting trees are also very beautiful, and the Sawbridgeworth specimens were strongly in evidence. This is a feature of such shows that might be extended with advantage; but except where orchard houses exist few private gardens include collections of Apples or Pears in pots, and the cost of transit would be heavy, apart from the risk of loss of fruits on the way.

With regard to varieties of special interest, I fear my notes would take too much space if transcribed now, therefore I will trouble the Editor with them for another issue, if he will allow me to do so. One more observation, however, I should like to make. I missed, because I did not know of, the Conference. I saw no bills. Can it be that the R.H.S. does not care whether visitors attend or not, so long as matter is obtained for its official *Journal*?—A Countryman.

SCHIZANTHUS PINNATUS.

This is one of the freest flowering annuals we have for pot culture. It is usually employed for the spring decoration of the greenhouse, where it blooms for a considerable period. A few plants in 6-inch pots, when well grown, afford numbers of useful sprays of butterfly shaped flowers, chiefly lilac or rose coloured. Some are beautifully spotted.

The plants grow to about the height of 2 feet. They may be allowed to form one main stem, which branches laterally, and forms a pyramidal specimen. The culture is simple. Seeds should be sown thinly in pots or pans in August or September. When germination has taken place, the seedlings must have light and free ventilation on an airy shelf in a cold greenhouse or in a frame. Prevent the seedlings touching each other while in the young state, so as to induce them to advance slowly and sturdily. When about 2 inches high each plant will be ready for placing singly in a 3-inch pot. Employ a compost of loam, leaf soil, sand, and a little charcoal crushed fine. In potting place the plant low down, the bottom leaves being allowed to touch the soil. Pot firmly, but in proportion to the amount of roots each plant has. Those with few roots should be potted more loosely, and if necessary in smaller pots. Place a light neat stake to each, so that the plants may be maintained upright.

Undoubtedly the best position for the plants from the time of potting is on a shelf close to the glass, where unobstructed light reaches them, and cool air circulates about them. Growth will be carried on slowly. This is of more advantage for the later culture than encouraging a tall rapid growth early in their career.

Watering must be managed so that the soil continues moist but not unduly wet. It is more desirable that the soil becomes slightly drier than otherwise during the dull dark period of November and December. The best temperature for them is one 45° to 55°, the latter being the highest advisable, in order to prevent drawing or weakening.

January is the best period to pot the plants finally into blooming pots. The advantage of having plants with good balls of roots and a limited extent of growth above the soil will now be obvious. Rooting power once secured, the vigorous advance of the plants afterwards will proceed. A similar compost as before recommended, with the addition of a fourth of decayed manure, will prove suitable. Six or 7-inch pots are large enough. Crock them moderately and carefully, placing over the crocks a little moss or fibre, with a slight dusting of soot. Cover that with a layer of compost, and then introduce the plant. Work in more soil, and press firmly round the ball of roots, using a blunt stick for the purpose. This being the final potting, it is important to compress a fair share of rich compost within reach of the roots. Firmness induces the multiplication of fine rootlets, and these are essential to a continued healthy condition.

Still give the plants a light position, but it may be necessary for them to be at a greater distance from the glass, owing to the introduction of longer stakes. Should it be necessary, however, to keep the plants from becoming unduly drawn, it would be no great difficulty to give a fresh stick as the plant required, withdrawing the old one, and inserting the longer one in the same hole.

Soon after the plants have become established in their final pots, side shoots will commence to develop. Plenty of room must then be afforded to each so as to induce a regular and even shape. If strict attention can be given and continued, it would pay to neatly tie out the lower shoots close to the rim of the pot. Other shoots might be trained at regular intervals above, the whole forming a pleasing pyramidal shape and an attractive object when in bloom. Those who object to stiffness and formality may simply insert one stake in the centre of the pot, train the main stem to this, and allow the side shoots to develop in a free natural manner.

As the season advances and the time for flowering approaches, the plants, pot-bound with active roots as they will be, must receive assistance from applications of liquid manure, Clay's fertiliser, or similar artificial compound. Stood among other plants in the greenhouse or conservatory in spring, the Schizanthus has a light and elegant appearance. Whether for rendering useful sprays for cutting or adding to the attractions of a group of flowering plants it is worthy of culture.—E., *Gravesend.*

Cratægus Pyracantha Lælandi.—The various forms in which this superb berried shrub can be grown gives it special value to the planter. As a climber, or rather trained against a building of almost any description, it is in berry very attractive and beautiful. Grafted on tall stems of any common variety it makes singularly effective standards. It can be trained, by using the pruning knife, into pyramidal form, thus when in full fruit becoming on a lawn as a specimen a brilliant object. It can be planted on the crest of a mound and then allowed to branch out freely and somewhat drooping, for the great weight of fruit carried will bring the branches down. Probably there is no berry-producing shrub, not even the Holly, that is so effective when in fruit as is this evergreen Cratægus.—**A. D.**

National Chrysanthemum Society.

A meeting of the Floral Committee of this Society was held on Tuesday last, Mr. T. Bevan presiding. The following novelties were awarded first-class certificates.

Madame Geo. Bruant.—An immense Japanese, with very long florets, drooping and slightly intermingling; colour pale rosy purple, dark towards the tips, centre lighter (Messrs. Pearson & Sons).

Vicomte Roger de Chezelles.—A large Japanese, centre florets incurving, golden yellow, shaded bronze, reverse silvery yellow (Mr. Godfrey).

Ambroise Thomas.—Japanese, decorative, pretty medium sized flower, with pointed thin florets (Mr. Wells).

Several others were shown in good form, Soleil d'Octobre, a pure yellow Japanese, being commended.

Dundee Chrysanthemum Society.

On this, the Diamond Jubilee of her Most Gracious Majesty Queen Victoria, the Society intends putting forth every effort towards making its annual exhibition of Chrysanthemums worthy the great event. Towards this end it is necessary that it receives the hearty co-operation of all the growers in the district of this the queen of winter flowers. It is felt that, were permission granted to all gardeners to compete in any of the various classes that are detailed in the Society's schedule of 1897, the result would be a display of this beautiful flower worthy the city and district—a floral fête that would remain a living memory and a record of great advancement in the culture of the Chrysanthemum during her Majesty's reign. The musical department of the carnival will be fulfilled by the engagement of a leading London band, and it is expected that quite apart from the usual attractions of this popular floral festival, not the least attractive to lovers of music will be the orchestral and instrumental concerts which the Council has arranged for. The dates of the carnival in the Drill Hall are 25th, 26th, and 27th November. The Secretary is Mr. W. P. Laird.

Orleans Chrysanthemum Conference.

The French National Chrysanthemum Society will hold a Show and Conference at Orleans on the 6th to the 10th November next. As an instance of the facilities given by the railway companies on the occasion of such gatherings it may be mentioned that all persons taking part in the Conference will have a reduction of 50 per cent. off their tickets. The programme is as under:—November 6th, Meeting of the Floral Committee at 9 A.M.; lunch for the Jury and members of the Conference at 11.30; meeting of the Conference at 2 o'clock; banquet at 7 o'clock. November 7th, Meeting of the General Committee at 10 A.M.; lunch at noon; visit to the various objects of interest in the town in the afternoon. November 8th, Visits to the leading nurseries. If the agenda of Saturday be not completed a supplementary meeting will be held on the 8th.

The subjects to be dealt with at the Congress are—Fertilisation of Chrysanthemums; What is the meaning of Races of Chrysanthemums? The best Composts and Manures to be used; Maladies and Parasites; Crown Bud and Terminal Bud; The drawing up of a list of varieties showing which of these buds it is best to take; Difficulties of Classification in the Alphabetical Arrangement of the Names of Chrysanthemums for catalogue purposes; The voting of the Society's medal, and settling the place where the 1898 Conference shall be held.—P.

A Lady Chrysanthemum Grower.

Lady Chrysanthemum growers are not to be met with any day, especially those who accomplish something above the ordinary in the successful culture of Japanese Chrysanthemums. For several years I have noticed a sprightly and active young lady carrying about pots of Chrysanthemums, tying, bud taking, disbudding, and otherwise manipulating her plants from time to time.

From rooting the cuttings to cutting the blooms she takes considerable pride in doing the work herself. Her plants, standing on the sides of the garden walks, duly fixed on boards, and secured to a wire, appear to be in excellent health. The plants are tall, being allowed to grow naturally. A fair number have the crown buds taken, but the greater part of the buds are terminals, and will give good, but late blooms. They are not grown for exhibition, but for house and church decoration, though she has been known to compete in a lady's table decoration class at a local show, using some of her most suitable blooms, and usually coming off well in the contest.

I feel certain, too, that that when her brother played in an amateur dramatic representation of "Our Boys," wearing a huge Chrysanthemum in his coat, it was one of her growing. She makes a creditable display of very fine flowers in November and December, lasting over Christmas and into January. She believes in something rich and strong as stimulants at this season, because the gardener who comes to mow the lawn and do other work may be seen carrying on his broad shoulders a pail of cow manure now and then, also to be heard referring to blood and fowl manure, not to mention Clay's, Pearson's, Standen's, and Thomson's, from which we may judge one or the other of which are employed.—S.

Early Flowering Chrysanthemums.

Chrysanthemums which flower freely in September and October come in very useful indeed for the majority of growers who require a good supply of flowers for various purposes during the period named.

Owing to the popularity of the large midseason varieties, early flowering Chrysanthemums do not receive that meed of support and attention which they deservedly merit. That they are not more grown is certainly remarkable, seeing that, as a rule, they do not require exceptional skill in culture. Upon the whole they have a style of growth that is free yet capable of furnishing an abundant display of bloom, good in quality.

Moreover, the blooms, especially of the smaller Pompon varieties, do not demand that persistent and careful disbudding which forms such an important feature in the cultivation of the prominent exhibition and many of the ordinary decorative varieties.

Some of the medium sized early Japanese varieties, however, are much improved by a little disbudding, in some cases to one bloom, in others to three or four, forming a spray. A considerable amount of interest and instruction may be derived by testing the capabilities of the various sorts, and ascertaining which are the best methods adapted to bring them to a maximum of effectiveness at a minimum of trouble.

What are known as September varieties do not always bloom at the time expected, but most of them will bloom early in October at the latest. This is a season when they are duly appreciated. The waning glories of the autumn outdoor flowers are fast departing in the presence of wet, wind, and a low temperature, but the Chrysanthemums are not quite so susceptible, for they are just approaching their full zenith of beauty.

It is desirable when practicable to cultivate the very earliest varieties in a suitable position outdoors. They cannot be otherwise than decorative if not cut, but there is certain to be a demand for those that are in bloom during the time of harvest festivals.

Some of the early flowering varieties commence flowering in July, more in August, but the majority in mid-September to mid-October. The varieties which bloom at the latter end of October are known chiefly as October flowering, occupying a place between the early and midseason varieties.

Perhaps the names and descriptions of a few of the best early flowering varieties may prove of interest to some not well acquainted with this class.

Alice M. Love is a comparatively new and moderately dwarf growing variety, which opens its first flowers when growing in a suitably moist and open position in July and August. The flowers are white, fairly large, and are best on terminal buds.

Flora is a splendid small golden yellow variety. It blooms early and freely and is very dwarf. The flowers are good both on crown and terminal buds, which is the case with most varieties of this size. It commences to bloom in July or early August, continuing until October.

Comtesse Foucher de Cariel is an exceedingly good variety, though not commencing to bloom quite so early as the preceding. It is a true Japanese flower, the florets being loose and free, giving the blooms a graceful appearance. The colour is an orange bronze. The height attained by the plant is 1½ to 2 feet. The blooming period is late September and early October.

Gustave Grunerwald is dwarf, reaching 18 inches to 2 feet. The colour is light pink. Commences blooming in August, continuing to October.

Madame C. Desgranges occupies a leading position among the early flowering varieties, not only for its earliness, but for its colour, which is white with just a tinge of yellow as the blooms are opening. With special cultivation blooms may be secured of large size and abnormal earliness. Some years ago a leading firm exhibited plants bearing several excellent blooms each at the July show of the National Rose Society. No early variety surpasses this for general usefulness, hence its universal popularity. Plants may be placed out in beds or borders, where they will furnish numbers of flowers for cutting. For the largest and finest blooms pot culture throughout the season is the most suitable. The growths must be restricted to a few only when large flowers are required, and one bud on a shoot should be the rule. It is not satisfactory unless disbudded freely.

G. Wermig.—This variety may be considered the same in all respects to Madame C. Desgranges except colour, which is yellow. It affords a fine contrast to the white variety, from which it is a sport.

Mrs. Burrell is another sport from Madame C. Desgranges. It is of a pale primrose colour, and blooms about the same time as the type, forming a compact plant 2 feet high.

Mrs. Hawkins is also a sport of a golden yellow, similar in habit and time of flowering, but not so free-blooming as the type. It is better for outdoors than in pots.

Lady Fitzwigram may be termed a rival to Madame C. Desgranges. It is of the same colour and very free in blooming. It is not so useful outdoors as the latter variety, but is very satisfactory in pots, attaining to its best condition under glass. Plants 2 feet high and well covered with bloom are attractive.

Madame Marie Masse is a new acquisition and an excellent bloomer. The plants grow to the height of 2 feet 6 inches, and possess a bushy habit of growth. It is a Japanese variety, has rosy purple blooms 4 to 5 inches in diameter, and makes an attractive specimen.

Mrs. Cullingford is a beautiful white with round, regular blooms produced freely. It is one of the best older varieties.

Fiberta ranks as a good-habited Chrysanthemum of the Pompon section, having small but beautifully formed lemon yellow blooms.

Frederick Pelé is a crimson red variety, good, but not such a free grower and bloomer as many others. Lyon is an excellent variety with rosy purple blooms of fine shape. The plant is a free bloomer, and has a desirable habit of growth.

Madame Piccol is another rosy purple variety, fine, but not so good as the preceding. Mr. W. Piercy is a sport from Madame Piccol. Its colour is distinct red, changing to a bronze brown. Good early reds are valuable, inasmuch as varieties of that colour are limited. Alice Butcher is a sport from Lyon. Colour red, shaded orange. It is a useful and attractive variety.

The above selection comprises many of the best varieties, both new and old, but there are many others worthy of cultivation. The best course to follow is to try all the varieties possible, and weed out those which are the least satisfactory.

The same selection will not succeed equally well in all places. Soil and positions available for their cultivation differ, though if the plants can have an open situation, they usually succeed in any soil, so long as rational treatment is afforded them.—E. D. S.

ROYAL AQUARIUM.—OCTOBER 12TH, 13TH, AND 14TH.

THE early autumn exhibition of the National Chrysanthemum Society was in every way satisfactory, and if the present show is a criterion of the material in hand for the November exhibition, we may expect something out of the ordinary at the next show. The trade exhibits were exceptionally fine and numerous.

Mr. N. Davis, Framfield, Sussex, was placed first for a group of Chrysanthemums and foliage plants, with a very tasteful exhibit. Mr. W. Howe, gardener to H. Tate, Esq., Park Hill, Streatham Common, secured second with a more formal display; while third place was assigned to Mr. J. H. Witty, Nunhead Cemetery. A keen competition was displayed in the class for twenty-four Japanese varieties, the first place falling to Mr. C. Penfold, gardener to Sir F. Fitzwygram, Bart., Leigh Park, Havant, with a very even exhibit. The varieties were Beauty of Teignmouth, Mrs. W. H. Lees, Phœbus, Mrs. C. H. Payne, Emily Silsbury, International, A. H. Woods, Madame Gustav Henry, Modesto, Madame Ad. Chatin, Eda Prass, Edith Tabor, Surprise, W. G. Newitt, Reine d'Angleterre, Alice M. Love, Mons. Chenon de Leche, Mutual Friend, and Phœbus. The second prize was taken by Mr. Jas. Agate, Havant; his best flowers were Milano, Mrs. J. Lewis, Mons. Chenon de Leche, Modesto, Madame Gustav Henry, and Dorothy Seward. Mr. N. Davis was third.

In the class for twelve blooms, distinct, Mr. F. G. Foster, Brockhampton Nurseries, Havant, proved the winner with good blooms of Edith Tabor, Mutual Friend, Emily Silsbury, Zealandia, and Louise. Mr. R. Jones, gardener to C. A. Smith-Rylands, Esq., Barford Hill, Warwick, was placed second with good blooms of Madame Ed. Rey, Mutual Friend, and Mrs. H. Weeks. Mr. J. Agate third. Mr. E. Such, Maidenhead, was the only exhibitor of twelve bunches of Pompons, being awarded first, and the same exhibitor was again first for six varieties. The amateur classes were very well filled and also showed a marked improvement in the quality of the flowers.

The tables of floral decorations are always an attractive feature here. In the chief class, Miss Nellie Erlebach, Chards, Stoke Newington, fully sustained the credit of the firm. The devices, bouquets, and baskets, being fully up-to-date, securing first prize. Mr. E. Such was placed second with a smaller display. A strong team of competitors contested the class for three epergnes, but Mr. D. B. Crane, Highgate, was decidedly first, with very handsome arrangements of yellow, bronze, and crimson Chrysanthemums, with appropriate foliage; Miss C. B. Cole, Feltham, second with a similar exhibit; Mr. W. Green, junr., Harold Wood, third with almost the same materials. In the class for two vases of Chrysanthemums, twelve large blooms, Mr. Jas. Brooks, gardener to W. J. Newman, Esq., Totteridge Park, Herts, was placed first with very effective vases; Mr. Norman Davis second; Mr. J. Tullet, gardener to G. Alexander, Esq., Warley Lodge, Brentwood, third. For a single vase of Chrysanthemums Mr. J. Tullet was placed first; Mr. D. B. Crane following with a fine vase; Mr. D. M. Hayler, gardener to Mrs. Langworthy, Greys House, Maidenhead, third.

Mr. H. Berwick, Nurseries, Sidmouth, exhibited a very fine display of Apples and Pears, in baskets and dishes. The fruit was remarkably well coloured and clean. An attractive exhibit of Apples and Pears was staged by Messrs. S. Spooner & Sons, Hounslow Nurseries. An artistic group of Chrysanthemums, beautifully arranged, came from Mr. W. Wells, Earlswood Nurseries, Redhill, comprising large flowers, decorative plants, bouquets, and arches, with Palms and trails of Virginian Creeper; Australie, M. Hoste Madame Gustav Henry, Emily Silsbury, Baronne Ad. de Rothschild, Thos. Wilkins, Iserette, and Edith Tabor represented the best of the large blooms, while the decorative class contained some very fine plants, Nellie Brown, a sport from Ryecroft Glory, being a distinct break and an attractive colour. Ambrose Thomas was also well shown; Louis Lemaire, a bronze sport from the well-known Gustav Grunerwald, was attractive; while the plants exhibited with large blooms were above the average. Mr. Eric Such, Maidenhead, exhibited a good collection of varieties grown naturally, forming a very bright exhibit.

A fine collection of Cannas came from the Swanley firm of Messrs. H. Cannell & Sons; the chief varieties were Paul Lorenz, Amie J. Chretien, Alphonse Bouvier, Golden Star, and Aurore, while a superb collection of vegetables, Chrysanthemums, and Violets completed the efforts of the firm at this exhibition in a satisfactory manner.

An enormous exhibit of Chrysanthemums and Zonal Pelargoniums was staged by Mr. H. J. Jones, Lewisham, comprising vases of large blooms, and bunches of the decorative section, the Pelargoniums forming a very attractive feature. Mr. W. J. Godfrey, Exmouth, had a large collection of Japanese varieties, all grown to show standard. The most notable were Golden Glow, golden yellow; M. Hoste, Mrs. J. P. Brice, chestnut red; John Seward, Mons. Rayonnant, a decided improvement on Lilian B. Bird; Mrs. Tucker Pain, Madame Phillipe Revoire, white; Soleil d Octobre, and Vte. Roger de Chezelles.

Messrs. Hawkins & Bennett, Twickenham, exhibited baskets of their new Zonal Duke of Fife, a good semi-double red, likely to become popular. A miscellaneous exhibit from Messrs. J. Laing & Sons, Forest Hill, comprised a collection of autumn flowering plants and a grand exhibit of Pears and Apples, in which most of the popular varieties were to be found, also Begonia Gloire de Lorraine. Messrs. Osman & Co., London, exhibited their flower vases, which have become so popular during recent years, also a fine display of dyed grasses and flowers. Messrs. J. Peed & Sons, Streatham, exhibited a variety of Apples, well coloured, forming a capital exhibit. Mr. T. S. Ware, Tottenham, sent an interesting exhibit of hardy flowers.

BULBS.

WHEN notions become firmly established it is very difficult to remove them, or convince cultivators that they are wrong, even by facts that are the outcome of practical experience. Perhaps no erroneous idea is more prevalent than the one that Dutch Hyacinths and other bulbous plants used for flowering in pots during the spring are not worth the labour and trouble of planting after they have done duty indoors. It would be difficult to trace the origin of such an idea, or the reason that has led to such a general opinion, but it is easy to prove that it has no foundation in fact, and is more than likely due to inexperience in the culture of bulbs. In a few soils Hyacinths, Tulips, Narcissi, and others may degenerate year by year, but in the majority they increase in numbers, size, and strength until they will yield flowers that cannot be surpassed by the second-class roots imported annually, or what may be known as first-class bedding roots. To attempt to plant out Roman Hyacinths, Duc Van Thol Tulips, Paper White, and Double Roman Narcissus that can be purchased at such a cheap rate would be a waste of time and labour. If they could be planted out direct from the forcing house such a step might be taken, but the necessary preservation needed to develop their growth and harden it to withstand the trying weather of early spring would prove a severe tax upon those with limited house or frame room at disposal for plant cultivation. With very early forced bulbs our experience has led us to the conclusion that the best course to pursue with them is to convey them to the rubbish heap directly they have flowered.

There are, however, tens of thousands of bulbs that are not forced, as they are allowed to come forward gradually and naturally in windows, greenhouses, cold frames, and similar positions. The majority of growers have bulbs of one sort or another in this condition, and if they are preserved after flowering as will be detailed they will with certainty increase in numbers and yield very fine spikes. The greenhouse is frequently robbed to ornament the dinner table and dwelling-room when the flowers could be gathered from outside beds and borders if care and a little forethought were exercised.

When the bulbs have been brought into flower under moderately cool conditions, a few days, or a week at most, in a cold frame is ample to harden them sufficiently to stand in a sheltered corner outside. From this point two courses are open—that is, either to retain them in pots until the foliage dies, or to plant them out in the position they are intended to occupy. Wherever they are planted they should be left undisturbed for some years, when they will pay abundantly for the trouble bestowed upon them. If the first plan is adopted they entail considerable labour in keeping them liberally supplied with water, or instead of thorough development their growth is prematurely brought to a standstill. This method is very frequently followed, so as to enable the cultivator, after the growth has ripened off naturally, to shake away the soil from the bulbs, and spread them out in the sun to dry and harden. It is contended that such measures are necessary, but the least labour and trouble is occasioned by the last method, and we have found that the bulbs do as well, if not better, the following season than when subjected to the artificial drying process. The better plan decidedly is to plant them out directly they have been well hardened, and then they complete their growth, and the foliage is ripened under natural conditions.

Failure may in many instances be traced to planting the bulbs in shrubbery and other borders in soil that has become exhausted by the roots of other trees. Hyacinths, Tulips, Narcissi, and other bulbs can no more be expected to thrive in unfertile soil than any other plant or tree, and yet such positions are frequently accorded them. Well developed growth and fine spikes of bloom cannot be produced from such positions, and under such circumstances we should not be surprised at them degenerating rapidly. They will do, however, on borders overshaded by forest trees, provided the ground is liberally supplied with food. We have a border planted three or four years ago, and although the spikes are large enough for cutting purposes—in fact, they are more useful than the larger ones—they will not compare with those grown in open positions and in good soil away from the roots of large trees.

The ground should be well dug and liberally manured as the work of planting proceeds; if this is done they will need no further care for two or three years, without Mignonette or other plants are grown on the

border during the summer. In this case—and plants of this description will do no harm after the plants are cleared off in autumn—the borders should receive a dressing of short manure in a fresh state. This should be forked into the surface, so that rains will wash the juices down to the roots ready for them when they commence activity. The bulbs will soon show their appreciation of such treatment.

The first season they may prove somewhat disappointing, and here no doubt is one reason why they have been regarded as useless after the first season. The nearer perfection the bulbs have been produced previous to importation the more certain are they to come small, for they frequently divide into a number of small bulbs, while many of the bedding ones will grow for a season before they do so to any extent. After the bulbs divide into a number, which they do rapidly when planted out without any artificial treatment, the same as practised in Holland, and attain their full development, that fine spikes are produced. A bed planted with bulbs that have flowered in pots, especially of Hyacinths, are certain to produce spikes of nearly every size. Ten years ago we planted out a bulb of Grand Lilas: for two years it remained a single bulb and produced one spike only each year; it has now increased to thirteen, and eight of them have flowered. When Hyacinths are grown three or four in a pot they should be planted out without division, for any attempt to divide them before their growth has been matured is certain to check them severely by the wholesale destruction of their roots. In planting be careful to place the bulbs at least 2 inches below the surface of the soil, or a little more, then the fork can be used without fear of damaging them.

Although we grow none in glasses we are certain that they also will repay for the trouble of planting in outside borders. A lady who only grows Hyacinths in glasses in the windows of her house was advised to plant them out after flowering, and her little flower beds are gay every year with the old bulbs that thousands would have thrown away as useless. When old bulbs are preserved they are often kept out of the ground too long, and I would rather plant them in July or August than leave them till November or December.—B. W.

ACACIA GRANDIS.

A LARGE proportion of the Acacias are natives of Australia, and from these we select one of the neatest and dwarfest species, more especially adapted for window or frame culture. Acacia grandis is a native of Western Australia. It forms a shrub of moderate size, and flowers freely while small. It is a most charming window plant for spring flowering, being at that season loaded with its golden yellow balls, and at all periods of the year its elegant foliage gives it an ornamental character. Its propagation is effected either by seeds or cuttings, usually by the latter method; they should be inserted in white sand or very sandy soil, and covered with a bell-glass or tumbler. As they are impatient of damp they require a little more care during the rooting process than those of the leafless species; the inside of the glass should be wiped daily, and, as soon as the cuttings are rooted, they must be potted off into sandy peat, and eventually into good fibrous peat, containing less sand. A flower spray of A. grandis is figured in the illustration.

As a companion plant to A. grandis may be recommended A. Drummondi, a plant of more recent introduction, and perhaps somewhat more delicate in habit. Many other desirable species are mentioned in catalogues, but a large proportion of these flower only when the plants have attained an inconvenient size.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—OCTOBER 12TH.

THE exhibition held in the Drill Hall on the above date was in all respects an interesting one. There were splendid Orchids, some grand Apples and Pears, magnificent collections of Michaelmas Daisies, while Chrysanthemums and other flowers were extensively shown. Mr. Woodward's collection of Apples and Pears was a magnificent one, and thoroughly deserved the gold medal which the Fruit Committee awarded.

FRUIT COMMITTEE.—Present: Phillip Crowley, Esq. (in the chair); with the Rev. W. Wilks, and Messrs. Hugo M. Müller, G. Bunyard, J. Cheal, G. W. Cummins, W. Pope, A. H. Pearson, A. F. Barron, A. Dean, W. Bates, G. Woodward, J. H. Veitch, J. Willard, J. Smith, G. Wythes, F. Q. Lane, G. Reynolds, W. J. Empson, R. Fife, and T. J. Saltmarsh.

The exhibits placed before the Fruit and Vegetable Committee were numerous, and fairly well varied. There were a few large collections of fruits from different exhibitors, and many of the most popular varieties were handsomely represented. J. Ester, Esq., Wakefield, showed a few Apples. The fruits were as a rule rather small, and consisted of Lord Suffield, Ecklinville, Warner's King, Stirling Castle, Alfriston, Emperor Alexander, and others. Mr. Rickwood, gardener to Lady Freake, Fulwell Park, staged a collection of upwards of six dozen dishes of Apples and Pears. Many of the specimens were good in shape, but generally speaking lacked colour. Amongst others were noted Potts' Seedling, Peasgood's Nonesuch, Wellington, Frogmore Prolific, Lord Derby, Beauty of Kent, Mère de Ménage, King of the Pippins, Ribston Pippin, Cox's Pomona, and Cellini Apples, with Pears Beurré Hardy, Pitmaston Duchess, Beurré Diel, Beurré Superfin, and Marie Louise. The Pears were mostly small.

Mr. G. Woodward, gardener to Roger Leigh, Esq., Barham Court, Maidstone, staged a magnificent exhibit of Apples and Pears. The size, richness of colouration, and the shape of Mr. Woodward's fruits are well known, and seldom has a better collection been staged in the Drill Hall than the one under notice. The Apples comprised Yorkshire Beauty, Melon, Baumann's Red Reinette, Hormead Pearmain, Stirling Castle, Calville Malingre, Tower of Glamis, Alfriston, Golden Spire, Waltham Abbey, The Queen, Wealthy, Washington, Margil, Tyler's Kernel, Lincoln Pippin, Potts' Seedling, Prince Albert, New Hawthornden, Lady Henniker, American Mother, Lord Suffield, Stone's, Cox's Pomona, Queen Caroline, Ecklinville, Golden Noble, Lord Suffield, Lord Derby, Warner's King, Belle Dubois, and others. Amongst the Pears we noted Duchesse d'Angoulême, Beurré Hardy, Emile d'Heyst, Gansel's Bergamot, Magnate, Doyenné du Comice, Prince Consort, Doyenné Boussoch, Beurré d'Anjou, and Beurré Dumont.

Pears and Apples were shown to the extent of sixty dishes by Mr. W. Offer, gardener to J. Warren, Esq., Handcross Park, Crawley. The

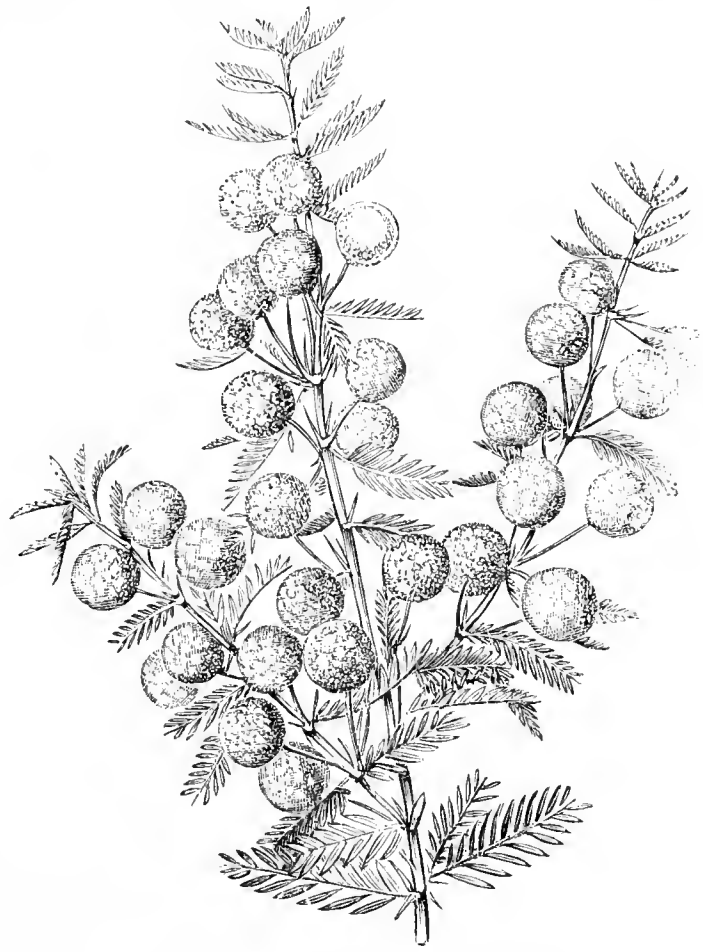

FIG. 56.—ACACIA GRANDIS.

Apples were beautifully coloured and the Pears were of good form. Of the latter the most conspicuous were Beurré Hardy, Nouvelle Fulvie, Thompson's, Nouveau Poiteau, Beurré Bosc, and Marie Louise d'Uccle. The best Apples were Emperor Alexander, Wealthy, Warner's King, Cox's Pomona, Peasgood's Nonesuch, Lord Derby, Blenheim Orange, Gloria Mundi, and Winter Quecning. Messrs. A. W. Young & Co., Stevenage, sent a large collection of ornamental Gourds.

A splendid collection of Cabbages was shown by Messrs. J. Carter and Co., High Holborn. The varieties comprised Filder-Kraut, Ellams' Early Dwarf, Dwarf Nonpareil, East Ham, Cocoa Nut, Nonpareil, Rosette Colewort, Sugarloaf, Wheeler's Imperial, Little Pixie, Winningstadt, and Enfield Market, with one or two Red varieties.

CLASSES FOR FLAVOUR.—Mr. G. Woodward secured the first prize in the class for the best flavoured dish of Apples with Cox's Orange Pippin in good form. Col. Brymer was second with Ribston Pippin. The last named went to the front in the Pear class with the delicious Thompson's, and was followed by the Rev. H. G. Palmer, who showed Marie Louise.

FLORAL COMMITTEE.—Present: George Paul, Esq., (in the chair); with Messrs. H. B. May, G. Stevens, D. B. Crane, J. F. McLeod, J. Hudson, T. Peed, C. J. Salter, J. D. Pawle, C. Jeffries, H. J. Cutbush, J. W. Barr, J. Walker, J. T. Bennett-Poë, C. E. Pearson, J. Fraser, E. Beckett, R. M. Hogg, H. Turner, C. T. Druery, and E. Mawley.

A magnificent display was made by the collection of Michaelmas Daisies staged by Mr. E. Beckett, gardener to Lord Aldenham, Elstree. The varieties were numerous, and the quality good. Some of the best were Amellus bessarabicus, cordifolius major, lævigatus, Harpur Crewe, dumosus, Robt. Parker, Madonna, Ariadne, sagittifolius, Orion, and densus. Messrs. Paul & Son, Old Nurseries, Cheshunt, arranged a beautiful stand of Roses in pots and cut. There were La France de '89, Viscountess

Folkestone, Madame Abel Chatenay, Gustave Regis, and Caroline Testout. The same firm also staged Michaelmas Daisies of good quality and well diversified.

Messrs. W. Cutbush & Sons, Highgate, sent handsomely fruited plants of Cratægus Lelandi, with Oranges and Skimmia japonica. The plants made a charming display. Messrs. J. Veitch & Sons, Ltd., Chelsea, showed a superb exhibit of Michaelmas Daisies. Many of the leading varieties were represented by profusely flowered pieces cut and placed into pots. Particularly noticeable were horizontalis, candidus, dumosus, Arcturus, longifolius formosus, Amellus bessarabiens, and cordifolius.

Mr. W. Patten, Camden Nurseries, Cranbrook, Kent, sent a few small bunches of Michaelmas Daisies, as well as some single Dahlias. Mr. George Prince, Oxford, made a charming display with Roses and their own foliage. The blooms were of fine quality. Mr. G. Wythes, gardener to Earl Percy, Syon House, Brentford, showed Chrysanthemum blooms rising from a groundwork of Maidenhair Fern. The flowers were of splendid quality, the colour development being rich. Mr. H. Deverill, Banbury, exhibited hardy flowers, amongst which Michaelmas Daisies were particularly conspicuous. Messrs. J. Peed & Son, West Norwood, sent small but splendidly flowered plants of Begonia Gloire de Lorraine.

Messrs. J. Veitch & Sons, Chelsea, sent Cratægus orientalis, Vitis vinifera purpurea, V. Coignetiæ, Coryopteris mastacanthus, as well as several plants of hybrid Rhododendrons. Mr. R. Owen, Maidenhead, showed some charming Chrysanthemums. The flowers were not large, but refined in character. Mr. H. B. May, Upper Edmonton, showed magnificently grown plants of Begonia Gloire de Lorraine. The plants were pyramids of bloom. Messrs. Hawkins & Bennett, Twickenham, staged a grand double scarlet Zonal Pelargonium named Duke of Fife. It is a very free bloomer and of brilliant colour.

Two boxes of Chrysanthemum blooms came from Mr. W. J. Godfrey, Exmouth. The varieties included Mons. Hoste, Admiral Ito, Mons. Gustave Henry, Snowflake, Mrs. J. P. Bryce, and Pride of Exmouth. Mr. W. Bain, gardener to Sir Trevor Lawrence, Bart., showed crested Begonias; and Mr. W. Penton, Chippenham, some good Violets.

ORCHID COMMITTEE.—Messrs. F. Sander & Co., St. Albans, arranged a bright little group of Cattleyas, mainly varieties of labiata. The plants were splendidly grown and clean. The group staged by Messrs. H. Low and Co., Clapton, was well diversified, and contained many Orchids of good quality and clear colours. There were Odontoglossums, Cattleyas, Cypripediums, Oncidiums, and others. Mr. H. J. Chapman, gardener to R. I. Measures, Esq., Camberwell, sent some fine plants of Orchids, amongst which Cattleyas were particularly conspicuous. Cypripediums were also of fine quality.

A beautiful group of Orchids was arranged by Messrs. J. Veitch and Sons. There were both quality and quantity, while the arrangement was exceedingly effective. Almost all kinds at present in flower were represented, so it would serve no useful purpose to give a list of names.

MEDALS.—The Fruit Committee awarded the following medals for exhibits. Gold medal to Mr. G. Woodward; silver Knightian medals to Messrs. J. Warren, J. Carter & Co., and A. W. Young & Co.; and silver Banksian medals to Messrs. Rickwood and J. Ester. In the floral section silver Flora medals went to Messrs. G. Wythes and H. B. May; silver-gilt Banksian to Messrs. E. Beckett, Paul & Son, and J. Veitch & Sons; and silver Banksian to Messrs. H. Deverill and G. Prince. The Orchid Committee gave a silver-gilt Flora medal to Messrs. J. Veitch & Sons, and silver Floras to Messrs. H. Low & Co. and H. J. Chapman.

CERTIFICATES AND AWARDS OF MERIT.

Apple James Grieve (G. Bunyard & Co.).—An early dessert Apple. The quality is very refreshing and the fruits keep well (award of merit).

Begonia grandiflora erecta cristata (W. Bain).—The flowers of this strain are crested on the majority of the petals (award of merit).

Chrysanthemum Madame G. Bruant (J. R. Pearson & Sons).—A large reflexed Japanese. The centre is silver white, the extremities being rosy mauve (award of merit).

Chrysanthemum Mrs. Wingfield (W. J. Empson).—A dwarf-growing flesh-coloured variety. It is very free flowering, and of good form (award of merit).

Lælia præstans Low's var. (H. Low & Co.).—A flower of fine form and substance. The sepals and petals are most delicate mauve, and the lip deep purplish mauve (award of merit).

Maranta picta (W. Bull).—A handsome form. The leaves are velvety green, of a deep shade towards the margins, and brighter at the midrib (award of merit).

Melon Croxteth Jubilee (B. Barham).—A scarlet fleshed variety of good quality. The flesh is very deep and luscious (award of merit).

Nandina domestica (J. Veitch & Sons).—A dwarf-growing shrubby greenhouse plant with crimson foliage (award of merit).

Odontoglossum grande Pittianum (T. & T. Pitt).—A beautiful yellow form of the type. The lip is the palest in colour, being creamy white. It attracted much attention (award of merit).

Vanda cærulea Rochfordiana (T. Rochford).—An almost white form of the type. Each of the organs is delicately tinged with purple (award of merit).

Veronica Silver Star (J. Veitch & Sons).—A dwarf green and white variegated Veronica that should become popular (award of merit).

Zygopetalum Jorisianum (W. Cobb).—The sepals and petals of this Orchid are green, blotched and barred with brown. The fringed lip is white (award of merit).

HELLEBORE POWDER AND THE ONION MAGGOT.

"KITCHEN GARDENER," on page 311, has great faith in the efficacy of soot as a preventive for the Onion maggot. I am afraid I must come under the same category as those unsuccessful users of the soot antidote, although I have used it when digging the ground, when preparing it for both seeds and plants, and repeatedly dusted the plants from a very early stage of growth, and after all the maggot has left me almost without a bulb.

This year I tried salt as a manure for the plants and a cure for the maggot, and I thought I was to succeed, as the plants appeared so strong and healthy, until in looking through them I found the maggot had commenced its work in earnest. I had come to the conclusion that soot and paraffin were of no avail in arresting its devastation. I therefore determined to give hellebore powder a fair trial. I dusted it on rather heavily on four different occasions, with four days between each dusting, and I am pleased to say the maggot stopped its work, and I have harvested a good crop of bulbs, even from those sown in the ground, which system in this district is generally supposed to be useless.

It would be interesting to hear if other correspondents have been successful with the above cure; it appeared to me if it would shift the caterpillar, the Onion fly would fight shy of it. — W. RUSHTON, *Kirkintilloch, N.B.*

FERNDALE.

FERNDALE, Pedmore, the residence of Wm. Roberts, Esq., is situated about 1½ mile from Stourbridge, on the main road between that town and Hagley. The neighbourhood abounds with princely dwellings and charming gardens, where plants, flowers, and fruit find congenial homes. It is respecting the gardens of Ferndale we wish to say a little, for they are not only renowned for the well-kept lawn, healthy shrubs, and borders teeming with brilliant flowers, but also Grapes and Peaches, as well as hardy fruits, Apples, Pears, and Plums, besides the smaller bush fruits, are all brought to a state of high perfection.

Entering the grounds from the main road the eye at once rests on the fine evergreens, which lend such a charm to the place. These consist chiefly of variegated Hollies, Araucarias, Cupressus, Pines of sorts, many other choice evergreens, and deciduous flowering shrubs. The front part of the shrubbery border was occupied with a series of circular flower beds, 6 feet in diameter, the divisional lines being formed of Veronica spicata, the centres filled in with "Geraniums" of sorts; one, Chelsea Gem, with white variegated foliage and pink flowers, was most effective. Others were occupied with dwarf Antirrhinums, such as Crimson King, White Queen, and Yellow Prince; these were exceedingly bright and striking. The groundwork between the circles was Aubrietia, dwarf Asters, and Ageratums.

In the pleasure grounds were many other beds, all possessing an individuality of their own. It is not necessary to enumerate each bed and the method of planting, but just two or three of the most striking. For instance, there was a large circular bed of scarlet Begonias, dotted all over with Dactylis glomerata, and an edging of the variegated Arabis. Another simple but very striking bed was a large circle with the old Perilla in the centre, next a broad band of Centaurea candidissima, another circle of "Geranium" Crystal Palace Gem, and an outer edging of Mangles' variegated "Geranium." Perhaps the most effective arrangement was a carpet bed, 22 feet long and 7 wide, and planted with Iresine Lindeni, Mesembryanthemum cordifolium variegatum, Alternantheras of sorts, Sedums, Golden Feather, a dwarf Thyme, exceedingly pretty; Antennaria tomentosa, Herniaria glabra, and an outer edging of Echeveria secunda.

Carnations were in strong evidence, and along the various shrubbery borders we noticed a large assortment of the very best of the herbaceous plants. We have dropped into these gardens at all seasons of the year, and at all times find a multitude of hardy flowers in bloom, as well as some rare deciduous shrubs. What with the perfect order of the place, the endless variety of plants and flowers, combined with the intelligence of Mr. Parks, the gardener, Ferndale is at all times a source of great attraction.

Passing along a more secluded walk we came unexpectedly on the hardy fernery, where a choice collection of hardy Ferns finds an agreeable home. The formation of the fernery was not an elaborate or pretentious piece of work, but it bore unmistakeable traces of skilful adaptation in its arrangement. Near at hand was the Nut plantation; it was not only that in name, but in reality—a plantation of Nuts. Every bush is carefully pruned year by year, and at the time of our visit the trees were literally weighed down with their heavy burden.

We now enter the walled-in kitchen garden, which is not only teeming with luxuriant vegetables, but the fruit trees were in fine condition. Down each side of the central path were fine specimens of bush Apples, many of them carrying good crops of fruit. Every branch stood clear and free of its neighbour, while the trees themselves were grand specimens of the pruner's art. We noticed such sorts as Gloria Mundi, Warner's King, Kentish Fillbasket, New Northern Greening, New Hawthornden, Peasgood's Nonesuch, and Court Pendû Plat. On the walls were some well-trained Plums and Pears in splendid fruiting condition. Of the former there were Kirke's, Jefferson, Golden Drop, Emperor, Green Gage, and Transparent Gage. Of Pears the leading sorts were Marie Louise, Williams' Bon Chrêtien, Passe Colmar, Doyenné du Comice, Beurré

Diel, Duchesse d'Angoulême, and Louise Bonne of Jersey. The north wall was furnished with the orthodox Morello Cherries.

Down each side the central path of the kitchen garden Chrysanthemums were in strong force. Before the year is out some of our garden friends will know about them at the leading shows in the district. They bore evidence of high-class culture, with the promise of "up to date" flowers. Mr. Parks is a formidable competitor in the Chrysanthemum arena, having within the last three years secured sixteen first-class prizes at Wolverhampton, Droitwich, and neighbourhood.

The glass accommodation is not extensive, but is made the most of. In one house we saw some good Grapes. The colour was good, while the "finish" was perfect. In the Peach house there was one large tree from which 385 perfect fruits had been gathered for table, besides many more used for other purposes. There were the usual greenhouse plants and Ferns, all healthy and free from blemish. We compliment the worthy owner, not only on the high keeping of Ferndale, but the masterly skill by which every part is managed.—QUINTIN READ, *Eresham.*

BRIEF NOTES ON ALPINE FLOWERS.

ACHILLEA TOMENTOSA.

ON page 246 I made reference to the pretty, Daisy-like Achillea ageratifolia, and I have now to draw attention to another dwarf member of the same genus, but totally unlike it in appearance and in colour. This is A. tomentosa—the "Downy Milfoil." It is of capital habit, and a leading work says, with truth, that it "is one of the best yellow-flowered species for the rock garden, having a dense habit." It is a native of Europe, and also of the North of Asia, and is perfectly hardy and able to accommodate itself to almost any conditions on a light and free soil. On a richer one it is liable to grow taller and coarser, and so to lose in some degree one of its merits as a rock-garden plant. The flower heads of bright yellow are individually small, but the plant is usually so floriferous, and the numbers produced on a small plant so great, that the general effect of this Achillea is very pleasing. This is added to by the small finely divided leaves being exceedingly woolly—a feature shared by the flower stems also.

In rich soils A. tomentosa grows to about 12 inches in height, but poorer soil will reduce this to as low as 6 inches, an advantage for ordinary rock garden purposes. Although not very particular in its requirements, it seems to prefer a sunny situation, and to look all the brighter if given a little limestone or lime rubbish intermixed with the soil. It is a pretty little plant, easily obtained at a moderate price.

CARDAMINE PRATENSIS FLORE-PLENO.

The little flower possessing this long name is only the double variety of the common Lady's Smock, which is so plentiful in many districts. It is not a very scarce or rare plant, but one occasionally hears it spoken of as one of more than usual rarity. It is neither this, nor is it exceptionally difficult to grow. In some gardens, indeed, it spreads freely, and increases not only by means of growth from the root, but apparently by the young plants which form on the leaves being dispersed and taking root. This singular provision for perpetuation and increase is, of course, known in some Ferns and other plants as well, but when pointed out rarely fails to secure increased interest in the double Lady's Smock. These young plants are produced on some of the leaves only, but are complete, although miniature, plants, only requiring favourable conditions to enable them to form perfect and full-sized individuals.

For lovers of flowers, however, the main interest of the double Cardamine lies in its pretty double flowers, either white or pale rose in colour. These are perfectly double, and, in addition to their beauty on the plant, are not to be despised for cutting purposes. The pale rose-coloured form is more plentiful than the pure white one. As may be expected when we consider the water-loving nature of the typical Cardamine pratensis, the double variety likes a rather damp position, and the flowers last longer if the place is partially shaded from strong sun. On the margins of little pools or bogs in the rock garden it will be found quite at home. It may also be mentioned that it is usually somewhat dwarfer than the single variety.—ALPINUS.

(To be continued.)

KEW NOTES.

IN the narrow border which skirts the south front of the T Range at Kew, something of special interest may be seen in flower at almost any period of the year. At present several good things are at their best. Against the low wall of the structure several shrubs are growing and flowering, which are more often seen in the greenhouse than outside.

Of these the dwarf Pomegranate (Punica granatum nana) is very bright. It is not trained closely to the wall, the side branches only being trained to extend the plant. It forms an upright-growing bush, with glossy lanceolate leaves 1½ inch long. The first flowers were open early in September, and now it is covered with open flowers and buds. The flowers are about 1½ inch long; the calyx is scarlet and fleshy, and lasts a considerable time; the corolla is scarlet also, but the petals are very flimsy and fugitive. A white-flowered variety is growing by the side of this, but is not producing flowers at present.

Another shrub of considerable merit is Medicago arborea, the "Moon Trefoil." The leaves of this are trifoliate, pubescent, and slightly glaucous. The flowers are produced in umbels, usually about eleven in each, from nearly every node on the upper parts of the branches. They are orange yellow in colour. Raphiolepis salicifolia is also flowering well; almost every branch is terminated with a raceme of flowers. A variety of Capparis spinosa is producing numerous white flowers and a few purple fruits. This has a little protection during winter. Among other shrubs on the wall, in or out of flower, are Abutilon megapotanicum, Calceolaria alba, Discaria longispina, Ligustrum lucidum tricolor, and Aloysia citriodora.

In the border at the foot of the wall a quantity of Amaryllis Belladonna are in flower. In addition to the ordinary form of this there are several plants of a variety which is better in every way. It has darker flowers, which are produced in larger umbels, on longer and stouter stalks than the type. In a corner a mass of Kniphofia Northiæ is seen to great advantage; this, however, is not in flower. A plant of Hibiscus moschatus is freely producing its large, blush-coloured flowers, and several other interesting plants are noticeable. An edging several inches wide is made to the border with Zephyranthes candida, which is nicely in flower.

Anyone who can afford space round a warm house to make such a border, will be amply repaid for the trouble by the great number of interesting plants he can grow from the little extra warmth afforded by the house and wall, and in such a border interesting plants which require rather more attention than other border plants can be more easily kept sight of, and there is not the same danger of small choice plants becoming smothered by coarser growing neighbours, as is sometimes the case in mixed borders.—K.

THE YOUNG GARDENERS' DOMAIN.

COLEUS.

THESE comprise many handsome summer foliage stove plants, which in growth and shape of leaves closely resemble the common Nettle. They are of little use for house decoration, as the foliage soon falls, but they are serviceable for what may be termed "rough decorations," by which I mean for bazaars, corners, and tables in small local shows. For such affairs the gardener is often called upon to send plants, and not wishing to risk damage to his most valuable, it is here that Coleuses and many others are found very useful.

They are propagated both by seeds and cuttings, the latter being more suitable. Sow the seeds in January in pans of light sandy soil, water and cover over with a piece of glass. The best position for the germination of the seed is on a shelf in a temperature ranging about 70°, and as soon as the seedlings appear remove the covering so that they may have all the light possible. When they are large enough to handle prick out into pans and place back again on the shelves.

Before they are large enough to pot into small pots it is easy to select those that are worth keeping. The slowest growing are usually the best, being more highly coloured than the quick and strong-growing varieties. Propagation by means of cuttings is by far the easiest way, and also the only mode in the case of named varieties to obtain them true. Cuttings may be inserted singly in small thumb pots, or three or four round the sides of a 3½-inch; and if placed in a propagating frame will soon commence to root. They may also be inserted in the cocoa-nut fibre refuse that is usually placed in the bottom of the frames.

When rooted pot into 3½-inch, using a compost of two parts loam, one part leaf soil, and one of sand; and as soon as the roots have commenced to take hold of the new soil place the plants in a position fully exposed to the sun, so that they may develop their handsome colours to the full extent. From the 3½-inch transfer to 5 or 6-inch, using the same material as before. The stronger-growing varieties will again want potting into 7 or 8-inch.

Give plenty of water at the roots during the summer, also syringing amongst the pots, but take care not to damp the foliage. Some growers pinch their plants to make them bushy, but I consider they make better specimens without. If the main stem is allowed to go ahead it will throw out side shoots as it advances, thus causing the plants to be pyramidal in shape. It is advisable to pinch the flower heads out as soon as they appear, for they are no good, and only spoil the appearance of the plants. In winter the foliage loses its brightness considerably and many leaves fall. When they begin to do this place a sufficient quantity for obtaining cuttings for another season on a shelf, or somewhere in a position where they are not an eyesore, for Coleus are usually objects of pity in winter. They require very little water at the roots at this season.

Mealy bug and red spider are partial to Coleus, and when plants are attacked it is advisable to propagate anew and throw the attacked ones on the fire.—ELVEDEN.

HINTS ON CYCLAMEN CULTURE.

AS Cyclamens are annually becoming more popular, a few hints on their culture may be acceptable to young gardeners. In the first place it is a matter of great importance to secure a good strain of seeds, which are sown by many growers between the months of January and April. I prefer, however, to sow about the end of July or early in August, and the plants should be in bloom in September of the following year. This is when flowers for cutting are scarce, and at their highest value.

Sow the seeds in an ordinary seed pan that has plenty of holes for drainage, placing 1½ inch of clean crocks hollow side down, and follow with a layer of coarse leaves. The compost of fibrous loam and leaf mould in equal parts, with a little sand, must be placed to within half an inch of the rim of the pan, and must be neither wet nor dry when used. Sow the seeds very thinly, cover to the depth of a quarter of an inch with

finely sifted material, water with a fine rose to settle the soil, and then cover the pan with a piece of shaded glass to prevent evaporation. A temperature ranging from 60° to 70° is suitable, and the soil should be kept moist, though not wet. The seedlings will appear in from five to six weeks, when the covering may be removed and the pan placed close to the glass, and shaded from strong sun with a pieee of thin paper. During bright weather damp the seedlings two 'or three times a day with a very fine rose.

This treatment will prove satisfactory until the plants have made four leaves, when they must be removed to a temperature of 40° to 45°, still keeping near the glass. Let them remain in this position until early in February, then remove again to the higher temperature, continuing the same cultural details. By the beginning of March the plants will be ready for potting. Preserve every root, and secure a little ball of soil to eaeh plant. Two-and-a-half ineh pots answer best for this pottiug, and they must be thoroughly clean and well drained. The compost may consist of good fibrous loam and leaf mould in equal parts, with eoarse sand and a 4-inch potful of Thomson's manure to a barrowload of soil. Always pot lightly, and let the corm projeet about half way out of the soil. After potting, water with a fine rose to settle the soil about the corm, and again place near the glass in the same temperature, keeping shaded from strong sun, and sprinkling the plants twice daily in bright weather.

In about seven or eight weeks the plants will be ready for a shift into a 4½ or 5-inch pot, aecording to the size of the eorm. The compost may be the same as recommended for the previous potting, with the addition of a fourth of old Mushroom bed manure to a barrowload of soil. Again place as close to the glass as possible, and eontinue to damp the plants on bright days. By the end of July or early in August the plants will be ready to transfer to their flowering pots. After potting, place the plants in an easterly or northerly aspeet, giving as much light as possible. Shade from strong sun, and sprinkle occasionally until the middle of August, after which this must cease. Avoid wetting the eorm when watering, as if this is done, the leafstalks are liable to damp and spoil both the flowers and the appearance of the plant. Flower spikes should show in September or October, when the plants may be removed to the conservatory to flower, which, with attention, they will do until the end of March. The flowers should not be cut, but pulled out with the thumb and finger.

After the plants have done flowering prepare a frame in the following manner:—Plaee plenty of old brieks and rubble in the bottom to insure good drainage, then a foot depth of compost similar to that recommended for the final potting of seedlings, bringing this close to the glass. Turn the plants out of their pots, partly shake away the soil, and plant out into the prepared frame, allowing plenty of room for the plants to develop. The best Cyclamens I ever saw were planted out on a Vine border, but it was an exeeptionally good summer. Water well after planting to settle the soil about the roots, and after the plants start into growth sprinkle on bright days. Towards the end of August lift the plants carefully, preserving every root possible; pot into suitable sized pots and place in a pit or frame kept rather close for a few days, afterwards removing to a house with a temperature of 50° to 60°, and keep near the glass. If these instructions are followed there will in the dark days of winter be Cyelamens which will be a pleasure to all concerned.—J. C., *Lancashire.*

FRUIT FORCING.

Vines.—*Earliest Vines in Pots.*—Well managed Vines in pots prodnee useful Grapes, and often better than Vines planted in borders, from the conditions of eultnre being more favourable. This is the case where the Vines are given bottom heat. To insure snecess the canes must be strong, thoroughly ripened, and duly rested. As a start must be made about the 1st of November to have ripe Grapes in March or early in April, the tree leaves and stable litter should be in course of preparation for affording a mild sweet bottom heat. The heat about the pots should not exeeed 65° at the start, bringing up the fermenting material to the level of the pots by degrees, so as to augment the temperature to 70° to 75° by the time the Vines are in leaf. Any Vines in pots required for starting later should be placed under cover, an open shed with a north aspect being suitable; but the pots must be proteeted with dry hay or straw, and mice and rats kept down, or the animals may render the Vines useless by girdling them at the collar.

Vines for Starting in December.—Pruning, if not already done, must not be farther delayed, as early and complete rest for a few weeks contributes to an even break. Pruning to two buds is usually followed by a good show of useful bunches, but if such has not been so in previous years, or larger bunches are desired, the shoots may be left a little longer, or pruned to the most promising eye nearest the base. What, however, is gained in size of bunch is usually lost in compactness thereof, unevenness of berries, and bad finish. Besides, bunches of 1 to 2 lbs. weight are quite large enough for early Grapes. Remove any loose bark, but avoid the close peeling and scraping that injures the rods, and wash them with tepid soapy water, 4 ozs. to a gallon of water, following where there has been red spider with a solution of 2 ozs. caustic soda, and 2 ozs. pearlash to 1½ gallon of water, or where there has been fungi trouble, use a solution of sulphate of copper 1 oz. to 1½ gallon of water; apply carefully, but just wetting every part with a brush moistened in the solution. Thoroughly cleanse the woodwork of the house and limewash the walls. Remove the surface soil down to the roots, if not to the whole extent of the border, for a distance of 3 or 4 feet from the stem, and supply fresh loam so as to encourage new fibres, and an extension of fresh roots from the collar, adding about a quart of steamed bonemeal and a gallon of wood ashes to each 3 bushels of loam, or supply some approved fertiliser, according to the instructions. Keep the house cool, dry, and airy until the time arrives for starting.

Houses of Ripe Grapes.—Thin-skinned Grapes are more susceptible to cold and damp than are the thiek-skinned varieties. This applies eqnally to Black Hamburghs and similar kinds as to Muscat of Alexandria and Madresfield Court, but Hamburghs do not require a temperature of over 45° for good keeping, and there must not be any deficiency of moisture at the roots, otherwise the Grapes will shrivel. Remove all dead and decayed leaves from the Vines where Grapes are now hanging, and look over the bunches for any shanked or decayed berries and burn them. A temperature of 50° is the most suitable for Muscat of Alexandria. Lose no opportunity of giving air when the days are fine, turning on the heat so as to cause a gentle warmth in the pipes, not so mneh to dry the atmosphere as to insure a circulation of air, which is the best safeguard against damp. Turn off the heat at midday, or soon after, so as to allow the pipes to cool, but not so as to lower the temperature below the night minimum. When the heat falls too low and the temperature is raised moisture condenses on the berries, and being stagnant the skin of the Grapes is more or less decomposed, and fungal germs find a medium of germination and soon set up speedy decay. There is no harm in a low night temperature, the fault lies in not giving air soon enough, so that the heat from the hot-water pipes or sun expands the atmosphere, and the moisture is deposited on the berries as well as on the glass. In dull weather, espccially during fog, it will he necessary to keep a genial warmth in the pipes, but the house closed, in which case the moisture will be condensed on the glass instead of the Grapes.

Late Grapes.—Thick-skinned Grapes require time to mature after they are ripe, though Alicante improves nothing whatever in keeping, and is at its best as soon as well ripened, and the same may be said of Gros Maroc. Mrs. Pince is, perhaps, the best quality late Grape with a thick skin, as it certainly is one of the most difficult to finish, and is at its best shortly after being ripe. Its great defect is not colouring well up to the stalk, and it makes no difference whether the bunches are large or small. It also loses eolour more than any other late Grape, becoming quite red, but will hang as long as any other, and retain its excellent quality even in a shrivelled condition. Started early, say in March, the berries set better, and the fruit ripens quite up to the shank, and when covered with its fine bloom is very taking in appearance. Alicante retains its colour well, and as a prelude to Gros Colman is a very desirable Grape, as it is good in quality, the vinous flavour being very refreshing, and the earthiness, as in Gros Colman, entirely absent, whilst its appearance is unrivalled by any oval Grape except Alnwick Seedling, which is one of the hest late Grapes.

The magnificence of Gros Colman renders it popular, as that goes a long way even with table Grapes, and is all-important for market. Its beautiful appearance whets the appetite, and the flavour is entirely overlooked, as that beside West's St. Peter's, less presumptuous in bunch and berry, is comparably bad; yet, when started early, so as to allow it time to mature, the berries are not only superb, but the quality is vastly improved. But its principal valuc consists in the easiness of its growth; the bunehes are always compact, the berries set well, they swell to a good size, and when the Vines are not overcropped, they colour well. It is far the best in quality when grown on the old red sandstone formation, though it does well on the alluvial silts, as do all the coarse vinous Grapes. For rich vinous quality no thick-skinned Grape can vie with West's St. Peter's, but it is of no use where appearance at table is the chief merit in a Grape.

Lady Downe's is not only the best keeping Grape (we have had it excellent in June), but is unexcelled by any late Grape for uniform excellence in quality, though only about half as taking in appearance as Gros Colman, and not giving nearly so much weight of fruit per length of Vine; it retains its richness to the last, simply because it contains more sugar, and mostly has a "smack" of Muscat. In white Grapes there are some aspirants for fame, but none takes a higher place than Trebbiano for appearance sake, while being firm, crisp, and sweet. There is Mrs Pearson standing well out in the white Grapes, and having quality, as well as other desirable properties; but, as a rule, the black Grapes hold the sway when neither Muscat of Alexandria or Canon Hall Muscat are in the race. There must be no deficiency of moisture in the border, and the atmosphere not allowed to become stagnant, but have enough warmth, with air, to keep it in motion, the temperature not being allowed to fall much below 50° until the leaves fall.

Vines not Ripening the Wood.—Any that are not yet hard and brown in the wood should have a temperature of 60° to 65° by artificial means, with a little air constantly. The heat from sun influence may run up to 85° or 90°, only let there be enough air to insure a circulation. The laterals should be reduced by degrees, bringing them down to the principal buds; and when there is no danger of starting these, the shoots may be

shortened to about two leaves above the pruning buds. This will cause the latter to plump, and by keeping the house rather warm by day, with ventilation, and turning off the heat at night, with free ventilation, the Vines will go to rest.

Renovating Vine Borders.—Where the soil is of a suitable nature and the cultural treatment proper, Vines flouri h for an indefinite period, but they are mostly planted in artificial borders and the roots confined to limited areas. These conditions result in the soil becoming defective in nutrition and sometimes unfavourable as a rooting medium. Thorough renovation in ordinary cases is desirable, but a partial renewal of the soil, or such portion of it as will secure active feeders, is generally attended with satisfactory results. Where Vines, therefore, are not in a satisfactory condition, no time should be lost in removing the soil down to the roots and picking it from amongst them, so as to displace as much of the old stuff as possible with fresh compost, and it is best effected whilst the leaves are upon the stems, but not before they have performed their functions to the extent of perfecting the buds and wood. In case the border is found very unsatisfactory, and the roots few and deep, it will be necessary to remove all the soil and renew the whole border, commencing with the drainage, which should be clear and 9 to 12 inches deep, with a 3-inch layer of fine material on the top, old mortar rubbish freed of pieces of wood answering perfectly. There must be a drain under the drainage to carry off superfluous water.

The soil should consist of the top 2 or 3 inches of a pasture, where the staple is a good yellow or hazel loam with one-sixth of old mortar rubbish, one-twelfth of charred refuse or wood ashes, and one-hundredth of quarter-inch bones, all well incorporated. Two feet depth of compost is ample, and the roots should be laid in the top foot and in layers according to their inclination, encouraging those from near and at the collar by laying them just beneath the surface, making the whole compact, and having the soil moderately dry. If the roots are inside and outside one part may be done one year and another the next without any danger of loss of crop. Take care to preserve all the roots practicable, merely cutting off broken and paring bruised ends smooth, and to keep them as much as possible from the drying influences of the atmosphere whilst the operation is in progress. Afford a good watering to settle the soil about the roots, then sprinkle in each square yard 4 ozs. of some approved fertiliser, mulch with about an inch of short manure, and cover outside borders with a few inches thickness of leaves with a little litter over them.

THE KITCHEN GARDEN.

Cabbage. The earliest raised plants ought now to be strong enough for transplanting, and already large breadths are out in some districts. It sometimes happens that the earliest raised and planted bolt the following spring, while others raised later have succeeded admirably. The grower will, therefore, do well to make successional sowings and plantings. The plan of succeeding spring-sown Onions with Cabbage, if not adopted previously, should be given a trial this season. Ground well prepared for Onions is, as far as fertility is concerned, in admirable condition for Cabbage without the addition of more manure of any kind. It is also best left undug, comparatively solid ground producing Cabbages with good hearts and fewer coarse outside leaves than is the case when they are grown on loose, rich ground. If hoed and cleared of weeds when the Onions were pulled, and again hoed on a bright day prior to putting out the Cabbage plants, the surface will be freed of weeds and the ground fit for cropping. Slugs are troublesome among newly planted Cabbage. Dusting the plants when damp with soot and lime and occasional hoeings among them are good remedies.

Endive.—Well blanched Endive is now in demand for salads. Not till the heart is well developed ought Endive to be blanched for use. It may be tied up similarly to Lettuce, and covered with inverted flower pots with their drainage holes covered; or fully grown plants may have boards or slates laid on them. Where they are in beds tying up and covering with mats answers well. At this time of year it takes from a fortnight to three weeks to blanch Endive properly, and only enough should be covered at one time to meet the demand for a week. It is yet full early to lift and store Endive in quantity, but it is well to be prepared for emergencies. Temporary protection may be afforded by dry bracken, strawy litter, hay, or mats.

Lettuce.—With the introduction of the early hearting Cabbage Lettuces has gone the necessity for taking so much pains with the raising and wintering of plants of Brown Cos and other varieties for planting out the following February or March. Where large quantities of Lettuce are wanted it is yet advisable to continue the plan of raising abundance of plants in the autumn. In some districts the Brown Cos varieties, if not too far advanced in growth, frequently pass through the winter uninjured, some duly planted out, and the rest in the beds where raised. Where these succeed well is in rows midway between lines of late-planted Strawberries, and which, market growers' fashion, are not to be allowed to fruit next summer; and they may yet be planted out on open, well-prepared ground generally. All things considered, sowing seed later in frames, and wintering the plants where raised, is the most reliable plan. Frames or cool pits that have been recently occupied by Cucumber, Melon, or Tomato plants may be utilised for the purpose. Frames generally should be given a sharp slope to the south, and the 6 inches of light loamy soil intended for the Lettuces should be raised, by means of other soil, or a solid mass of old hotbed manure, to within 5 inches of the sashes. The second week in October is soon enough to sow, and thin broadcast sowing is preferable to drilling in the seed. The sashes should be kept on till the seed has germinated, afterwards giving abundance of air. Additional protection should be afforded whenever a severe frost is imminent.

Tomatoes.—Where much wet weather was experienced during August open-air Tomatoes are, and have been, badly overrun by the Potato disease. Those least affected owe their comparative immunity from disease to the fact that the plants were sheltered or kept drier by wall copings. In any case the time has arrived for cutting all the late or green fruit in bunches, hanging these up in a dry warm house or kitchen to ripen. The half-grown fruit ought to be turned to good account in the making of pickles.

Crops Under Glass.—Much fruit is still hanging on the old plants, and this ought not to be sacrificed. In most instances the house room is wanted for Chrysanthemums and other winter-flowering plants, but this need not necessarily involve rooting up the Tomato plants. The fruit ripens much better on the plants than off them, and the way out of the difficulty is to trim off the Tomato leaves and superfluous growths. Younger plants ought to be carrying crops already well advanced toward ripening as well as successional clusters. If growing in pots, boxes, or narrow borders they must be fed liberally at the roots, otherwise the flowers now opening will fail to give fruit. The best crops are produced by plants trained thinly up the roofs, and these must be kept free of all side or superfluous growths. On the least signs of their becoming too weak to continue setting crops top them beyond the last bunch of flowers that are showing. Keep the plants constantly moist at the roots without slopping much water about the house. Disease will not be troublesome if the houses are kept warm, dry, and airy. Distributing the pollen by means of a camel's-hair brush, or by smartly tapping the stems of the plants towards noon every day, is a good aid to fruit setting.

THE BEE-KEEPER.

Storing Spare Combs.

It will be necessary now to devise some means of storing all spare combs where they will be free from the wax moth until required for use again another season. It is a well-known fact that if the combs are left exposed in a damp place throughout the winter the wax moth will play such havoc with them that they are practically useless, except for melting down. But so much of the wax will have been consumed that they hardly pay for the trouble, and as wax extracting, even at the best, is not one of the most pleasant operations in connection with bee-keeping, a novice may at the first attempt with moth-eaten combs be inclined to give the business up in disgust. It is, therefore, worth taking a little trouble in storing the combs, so that they may be as clean and sweet the following spring as when stored away the previous autumn.

There are various ways in which this may be successfully carried out. A cupboard in a room in which there is a fire occasionally answers the purpose admirably. If the shelves are covered with paper it is an advantage, as any débris from the combs may be cleared away with the paper on the removal of the combs. Place the combs in the same position they occupied in the hive, and a little air will then pass between them. This is a much better plan than laying the combs on each other. On every shelf place a few lumps of naphthaline, and cover the whole with sheets of paper; this will exclude the dust, and the naphthaline will keep the wax moth away.

The plan I invariably practise, and it is within the reach of all, as the expense is nominal, is to obtain some large boxes. These are placed in a dry position, and lined temporarily with paper. The bottom of the box is covered with a piece of calico or some similar material, which is well sprinkled with carbolic acid. The box is then filled with combs, which are closely covered with another piece of calico similarly treated. The lid of the box is placed in position, care being taken that mice cannot gain an entrance, otherwise they will soon ruin a number of combs, even if there are no stores in them. Combs treated in this manner will remain in good condition for at least a year. No insects will exist where there is a strong smell of carbolic.

If during the winter there is any fear of the strength of the carbolic escaping from the box the covering on the top of the frames may be removed and sprinkled at any time. It is advisable to expose the combs to the air for a few days before using them, otherwise the bees may not take readily to them. Clean tough combs being so useful for extracting purposes, a store of them in hand is an advantage to bee-keepers.

Unsealed Sections.

A correspondent writes:—"I have several partly filled sections. Would it be an advantage to store them for use another season without extracting the honey?" All unsealed sections should be passed through the extractor on their removal from the hive at the end of the season, and fed back to the bees. If unsealed stores are left on the hive for a few weeks after the honey flow is over the bees will

carry it down into the brood chamber, and the bee-keeper will be spared the trouble of removing it. But I do not recommend this plan, as I have found the bees invariably do much better when the supers are removed after the honey flow is over, and all necessary feeding done at once. It is not advisable to store sections having unsealed honey in them with a view to using them another season, as the honey being unripe would ferment, and instead being a help to the bees would only prove a hindrance, as they would remove it before placing new honey in the cells.

After the sections have been passed through the extractor they may be placed on the top of a colony to be cleaned of any honey adhering to the combs. If the sections only contain a small quantity the bees would clean them out without the trouble of placing them in the extractor. If this is done evening is the best time for the operation, as they will be quite dry the following morning and in good condition for storing.

Reduction of Entrances.

It will be an advantage to keep the entrance to all the hives reduced for a few weeks longer, an inch will be quite sufficient at this season. Owing to taking this precaution in August no robbing has taken place; wasps, though, are ever on the alert, and the fine weather experienced during the past six weeks has had the effect of causing a great increase in these pests. Early in the season few wasps were visible, but latterly they have increased at a rapid rate. If wasps once gain an entrance to a colony of bees they will soon rob them of their stores. By reducing the entrance to the hives the inmates have a much better chance of keeping intruders out than if it were the full width. The nights are now much cooler; frosts may be expected at any time, and with the advent of frost stocks of bees will not be much troubled with wasps.—An English Bee-keeper.

TO CORRESPONDENTS

*** All correspondence relating to editorial matters should, until further notice, be directed to "The Editor," **8, Rose Hill Road, Wandsworth, London, S.W.**, and **NOT** to Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Bothy Customs (*Young Gardener*).—According to your narrative you appear to be always on duty. That is one extreme; the other is never on duty—men out of situations. Reason, mutual comfort, and prosperity are to be found between those two extremes. Your letter shall have further attention.

Chrysanthemum Sport (*A. Robertson*).—The sport from C. G. Wermig is a flower of much beauty, and we think distinct from any at present in commerce. The florets in Mrs. Hawkins and Mrs. Burrell are pointed, while in your flower they are round ended and of considerable breadth. We think the variety is a promising one, and recommend you to submit flowers to some trade grower and get his opinion thereon.

Chrysanthemum Disease (*A. E.*).—Your plants appear to be attacked by a fungus said to be new to the Chrysanthemum, and first referred to in the *Journal of Horticulture* by Mr. Abbey. It is a serious affection. Syringe at once with sulphide of potassium, half an ounce to a gallon of water, laying the plants on their sides, so as to get at the spores, taking the plants outside, as the sulphide smells badly and discolours paint; or use permanganate of potassium, 1 oz. to 3 gallons of water. This will not hurt anything but the fungus, though it will dye the flowers its own colour, or stain them. Anti-blight powders applied *early* act as preventives. Mr. Abbey will probably have something more to say on this great scourge in due time.

Chrysanthemum "Crown of Thorns" (*R. Brown*).—Presumably the variety is Madame Carnot, which is addicted to the production of extra growth shoots in the place of developing flower buds when the plants are immature and the buds "taken" too early. The latter in the case of this variety would be so. Hence the growth formation instead of bud swelling.

National Chrysanthemum Society—Rules for Judging (*W. G.*).—For the catalogue of the National Chrysanthemum Society you should write to Mr. R. Dean, Ranelagh Road, Ealing. The judging code is published by the Royal Horticultural Society, and if you send 1s. 1d. to the Secretary, R.H.S., 117, Victoria Street, Westminster, it will be forwarded to you post free.

Scots Fir Shoot Bored by Insects (*W. H.*). — The beetle (we only found one) is the Pine beetle, Hylurgus piniperda. These have bored through the side of the shoots and eaten their way for an inch or two along the pith, some hibernating in them, but most on the ground amongst rubbish. The tunnelling is not for breeding, but feeding purposes. You ask for a remedy. The best we have tried is to cut off a quantity of young Scots Fir tops, thinning off all the branches, and lay these traps about in the young plantation, but so that the under side will not rest on the ground. This being done in autumn, the female beetles lay eggs in them when the time comes round, and by collecting them at the end of May or during June there will be many of the creatures under the bark, when burn them.

Peaches for Wall Case (*Peach House*).—It would certainly be better to raise the wall a foot or 18 inches or even 3 feet, and then have a lean-to roof, the house not less than 7 feet 6 inches wide. We should have front lights 3 feet in height, or rather 18 inches of glass and a foot of wooden ventilator below, this part made to open from bottom outwards by means of crank and lever movement, and at the top of the house 2 feet 6 inches wide lights the whole length of the structure, and lifting upwards from the bottom by similar movement to the front lights. This would save much time and give thorough ventilation, an important matter in growing either Peaches or Tomatoes. The former would be confined to the back wall; then you would have the front for the Tomatoes, taking care that these did not shade the trees on the wall, then you could grow both well, as we have done for many years. The best very early Peach is Alexander, followed by Hale's Early (Dr. Hogg you have, being very good) followed by Dymond (Grosse Mignonne), also Bellegarde, excellent. Your Nectarines could not be bettered unless by adding for very early, Early Rivers, and Humboldt to come in before Pineapple.

Irish Peach Apple (*L. H. C.*).—This Apple, like the Cornish Gilliflower and some others, is prone to bear at the ends of the shoots, and these, therefore, must not, after a tree is formed, be systematically shortened. There is in fact, and as a rule, a disposition on the part of most pruners to shorten the extension branches of trees too severely, this resulting in an overabundance of succulent growths, by which numbers of trees are "choked." If your tree has become too crowded thin out some of the branches, so that the leaves of one do not touch those of the other, choosing for removal the least promising as fruit bearers, and you may do this at once. If the tree has got into a stubborn state, making little fresh growth, and if more is needed for invigoration, you may cut off the ends of a few branches here and there—say, about one-fourth at regular distances over the tree—to the first clear wood you can find behind the terminal blossom buds. This may result in fresh growths pushing for producing healthier bearing tips, when some of the older and more exhausted may be removed. By thoughtful action on those lines a tree may be kept healthfully productive, especially if, as may be needed, a few pailfuls of liquid manure be given to the roots now and at any convenient time. The individual peculiarities of varieties of fruits cannot be treated in small works, in which space is so limited that it has to be turned to more generally useful account.

Muscat of Alexandria Vine Roots (*A Constant Reader*).—The insects in the soil are woodlice, and may possibly injure the Vines by eating the young rootlets. The roots themselves are healthy, but evidently in too close and wet soil, otherwise there is nothing wrong with them. We do not know where you could secure a free analysis of the soil. If the roots are deep it would be advisable to lift them, relaying in fresh soil nearer the surface. To secure plenty of fresh rootlets you may notch the strong roots at 18 inches distance apart, making the transverse cut on the side of the Vine and the sloping as the direction of the roots. If this were done it would give much better value than analysis, as it is action that is needed on sound cultural lines. Of course the analysis would indicate the contained elements of the soil, but afford small, if any, clue as to which and to what amount available, leaving the more important question of staple untouched. So far as we can see the soil needs lime, say 1¼ cwt. per rod, which we should procure fresh, break up so as to spread evenly, and leave on the surface to air-slake, and after a month or six weeks point into the soil as evenly as possible without injuring the roots. If in a bad state we should lift the Vines, as before stated, and give them a fresh start in sound material. The soil appears rich and good, only needing lime and opening material, such as calcareous gravel. This is often better as a dressing for Vine borders than manure through the staple being too close, hence, as you say, sticky, mud-like, and deprived of air. Let it in, with lime, and having efficient drainage, all would go well, as it appears to us, with the Vines.

EDITORIAL NOTICE.—It is particularly desired that all communications, parcels, catalogues, and newspapers intended for the Editor, be sent direct to 8, Rose Hill Road, Wandsworth, S.W.

The Thomson Memorial (*C. B. E.*).—We know that presentations have been worthily made to Mr. David Thomson, but do not remember whether that which you have in view was among them. As you clearly know to whom to write on the subject, would not a direct application be the best means of acquiring authoritative information? The Rose question cannot be attended to this week.

Diseased Tomato (*A. T. S.*).—The fine fruit is attacked by black spot or stripe fungus (Macrosporium lycopersici) and pushing out growths—the light-coloured substance. The mycelial hypha is descending into the flesh, and making for the seed cavities, where arrived, it fixes on the seeds, and certainly goes over with them in the integument; then, when the young plant starts on its own account, the parasite wakes up, and, entering it, causes it to die off without "cause or reason." This is a form of "curl"—"sleepy disease" or "sudden collapse." It is the worst of all Tomato diseases, and can only be avoided by clean seed, and preventing, as far as possible, moisture hanging on the fruit by giving plenty of air, some always with a gentle warmth in the pipes. Light dustings with any of the fungicides advertised act deterrently; but the chief art is keeping moisture from settling and remaining on the fruit.

Names of Fruits.—*Notice.*—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. *In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing.* The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. *They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state.* (*H. F. F.*).—Round Winter Nonesuch. (*G. S.*).—1, Cat's Head; 2, Gravenstein; 3, Ecklinville Seedling; 4, unknown. (*E. H.*).—1, Souvenir du Congrès; 2, Duchesse d'Angoulême; 3, Beurré Superfin; 4, Doyenné du Comice. (*C. A.*).—1, New Hawthornden; 2, Hollandbury; 3, Newton Wonder; 4, Ribston Pippin; 5, Gascoyne's Scarlet Seedling; 6, Warner's King. (*P.*).—1, Sandringham; 2, Old Nonesuch; 3 and 4, evidently the same variety, a local seedling. Thank you very much for the bunches of fine Violets gathered from between the Apple trees. (*Wm. Thompson*).—Nos. 1, 2, and 3 are either King of the Pippins or seedling forms of it; 4, Golden Harvey, also known as Brandy Apple; 5, not known nor worthy of a name; 6, Pearson's Plate; 7, Beurré Hardy, poor specimen; 8, Swan's Egg.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*R. B.*).—1, Aster cordifolius elegans; 2, A. fragilis carnea; 3, unknown. (*R. W.*).—1, Begonia maculata; 2, Escallonia macrantha. (*P. C. L.*).—1, Ixora Fraseri; 2, Solanum jasminoides; 3, Eucharis candida; 4, Mina lobata; 5, Cypripedium selligerum. (*E. G.*).—1, Coccaloba platyclaba; 2, Campanula isophylla alba; 3, Justicia carnea. (*Inquirer*).—1, Helenium autumnale; 2, Helianthus rigidus Miss Mellish; 2, Rudbeckia nitida; 4, Solidago altissima; 5, S. latifolia; 6, Funkia Sieboldi. We do not think hares or rabbits will do any material injury to the bulbs. (*J. B.*).—1 and 2, Erigeron pulchellum; 3, Aster novæ-belgii lævigatus. The Apple is New Hawthornden. The other specimen is the larva of the Goat moth.

COVENT GARDEN MARKET.—Oct. 13th.

Royal Gardeners' Orphan Fund.—*Secretary*, Mr. A. F. Barron, The Royal Gardeners' Orphan Fund, Chiswick, W.

BIRDS, INJURIOUS AND OTHERWISE.

This subject is a very wide and vexed one. So few persons seem able to take a steady, clear view of the matter; prejudice is so strong, and this prejudice so often springs from ignorance, and ignorance on this topic exists in little suspected quarters. If anyone live in or about a village, and will be at the trouble of looking at a field of ripening corn, say Wheat or Barley, he will not require any words of ours to make him understand fully the ravages committed by that fearless little bird, Passer domesticus.

The sparrow appears on the scene as soon as ever there is an atom of nourishment to be got out of the grain, when it is still only a mass of sweet milky substance, and he harrasses it till the vexed husbandman has got the remainder safely stacked. It is not altogether what he eats, but what he destroys; ears, bent stalks, broken as though there had been the heaviest of hailstorms. He comes, not singly, but in battalions, in myriads—like the sand of the seashore—and his visits also are not transitory. He seems, too, to bear a charmed life—too wary for traps; too numerous for gunpowder; too strong and tough for hard winter frosts; and too cunning to build all his nests within reach of boys, be they never so active.

Another grave charge is laid at his door—by his pugnacity he fairly drives away other birds of the swallow and martin families, which rank amongst the best of our insect destroyers. We know Wheat growing is about played out, but somehow yet we have found no efficient substitute to entirely take the place of Wheat

straw, and whole acres are completely destroyed by the ever wakeful lark, which is on the new sown corn earlier and later than any merely human tenting boy. These birds are, we believe, confined to certain areas, and where they do exist work irreparable misehief. Among other small bird pests you may fairly rank the finch tribe, which are most abundant in every hedgerow; in fact, next to the sparrow, they are the most destructive birds we have, and their numbers seem ever to be on the increase.

The greatest pest of all, and a steadily increasing one, is found the hordes of wood pigeons, a most ravenous bird, and one hard to destroy. Like the locust of old no green thing escapes him, but if he has a special weakness it is for the young and tender Clover, the seed of which has cost so much per pound — Clover so difficult to tide over unforeseen contingencies and so valuable to the farmer whose main hope and stay are his sheep.

Shoot him, you say. Well, just come and try. Set up decoy birds, hide yourself all day in hedge or hut, ask your friends to help, be very successful and bring home at least fifty. "What are these among so many?" Only a mere handful, and the birds are warier than ever. No sooner is the corn ripening than they are there, trampling and breaking down acres, leaving the crop as flat as though rolled. If you can get hold of a few young birds now they are delicious eating, but this is only a poor revenge, as you are eating gold drawn from what ought to be your golden grain. Then, again, should a sharp spell set in, and food become scarce, your Turnip fields will furnish forth many a good meal. Nine-tenths of these pigeons are either "Hardy Norsemen" or canny Scots. History repeats itself, we feed and nourish the northern invader.

Rooks, too, are foes to fear, but not foes so implacable as the wood pigeon. We do believe, and know, that the rook sometimes comes as a friend to rid us of the dreaded wireworm, but in return he takes toll of our cornfields, harrasses the newly formed Potato, and worries the life out of young Turnips. Perhaps, however, that last accusation should be modified; no aged rook will recklessly pull up a young Turnip unless he is absolutely sure that there he will find a wireworm, in which case the plant would never have come to maturity. Young rooks are the offenders here; it is their "first season" and they have much to learn, the lesson proving an expensive one to the farmer.

Our minor industries suffer, too, from the smaller birds. Unless fruit is grown in great quantities it is impossible without elaborate netting to reserve even a portion for the grower. This year we noticed, too, for the first time, that birds were feeding on the ripe Victorias as well as on the early summer Apples, such as Irish Peach. For the Peas, too, there is an adversary. A goodly row will be tattered, torn, and ravaged in a very short time by the active hawfinch. If we count these birds our enemies, we must in all fairness tell something of the good reaped by the annual visit of the black-headed gull. Alas! that it is not more common, for its services are of untold value.

Coming, as it does, about March 6th, and staying till the last week of July or 1st of August, the food it requires is enormous. For worms and grubs it follows fearlessly the ploughman with his newly turned furrows; it haunts the grass land, and rids our fields of pests innumerable. As the young are hatched the need of a good food supply increases tenfold, and the busy birds scour the country day and night. After rain the fields are literally alive with these faithful white-winged helpers.

Do you ever give a thought to the chattering vivacious starling, so active in habit, so brilliant in his black and gold plumage? He is a gregarious bird, too, and visits us in large flocks. If the winter be very severe we lose sight of him, or at least only a few stragglers remain. This open season has been all in his favour. His bill of fare is principally insects, grubs, and the like. He may pick up a bit of grain in the stack yard, or be tempted (and who is not?) by a ripe Cherry; but it really only comes as a well-earned wage. We should sadly miss him if by folly or for fashion he were ever exterminated.

Much has been said and written about preserving the balance of power in Europe. People and kindreds are happier and safer if no particular nation has the ascendancy, and so in the kingdom of Nature. A wise Providence, consulting the best interests of the many, made this world one harmonious whole. Man, the creature of a day, upsets that harmony, and consequently suffers. Why are we plagued and harrassed by these hordes of small birds, to say nothing of the inroads of rats and mice? How rarely do you see any of the hawk tribe save on the keeper's gibbet? And no longer does the "Ivy-mantled tower" prove a home and refuge to the "moping owl." He used to be a familiar object in tower, barn, and hollow tree, and he did much to check the smaller birds and mice. The hawk, too, must eat to live, and not even the most rabid keeper can accuse him of feasting entirely on young partridges or hand-reared pheasants.

We do not recognise our best friends, and kill and exterminate those whose life is spent in doing us service. Where do you find a better mouser than an owl with a nest of fluffy, solemn-looking babies? No one knows better than the farmer the havoc and destruction the prolific mouse can work in a stack yard, and no man should be as strict a preserver of these useful birds as he.

WORK ON THE HOME FARM.

We have been thrashing Barley, and find the yield as disappointing as we had been warned it would be by others who had tried it. There is plenty of bulk to thrash, but the grain is too small, with too much tail corn to yield satisfactorily. Quality and colour are good, and 33s. per quarter is the best price we can make. A little more size would have increased the value to 40s., or near it. Four quarters per acre at 33s. does not multiply into anything very remunerative.

We have tried lifting Potatoes, but they are not fit, and we have had to stop. Here, again, the influence of the summer drought is shown in the smallness of the numerous tubers. Four tons per acre is the highest estimate of the quantity deliverable, and four tons at 60s., the present price, is another total very far from satisfactory.

The heavy rain of last week has been followed by beautiful weather, with just a slight suggestion of frost. This warns us to have the roots up as soon as they are ready. Some farmers are talking of taking their Mangolds up, but they are very full of growth yet, and are certainly not fit to store.

The difficulty of last year as regards the scarcity of hands for Potato picking has induced the school authorities of many parishes to alter the arrangements for the summer holiday, and after giving a fortnight during the early part of harvest, are giving three weeks in October. This will be a great boon to both farmers and parents, as many children who have not passed the necessary standard are quite able to pick up Potatoes after a digger.

Sheep are getting well on Turnips, and we have just been dipping them. Ewes are now with the ram, and must be kept in thriving condition to insure a good fall of lambs. A little Barley, say ½ lb. per head per day, is a good thing for breeding ewes just now.

Young cattle under twelve months must be closely watched to see that they do not lose flesh; they can run off very quickly, and if allowed to run out during the day, they would be better up at night with an allowance of hay, even if it be but a small one.

REMARKS.

3rd.—Rain from 2 a.m. to 5 a.m.; cloudless morning and bright afternoon and evening.
4th.—Bright sun from sunrise to 11 a.m.; overcast with frequent drizzle in afternoon; fair evening.
5th.—Generally sunny, but occasional cloud.
6th. Fine and pleasant, with frequent sunshine.
7th. Fog rather dense till 11 a.m., then bright sun; bright night.
8th.—Fair, with occasional sun during day; rainy from 7.30 p.m. to 9 p.m.
9th.—Fair early; generally sunny from 9 a.m. to 2 p.m., and cloudy after.

Temperature much below that of the previous week, and decidedly below the average. Scarcely any rain.—G. J. SYMONS.

INTELLIGENCE IN PLANTS.

THE DISTRIBUTION OF SEEDS.

FOR many years past I have thought that a full account of the various methods pursued by Nature in providing for the maintenance of the plant world would be a very interesting one, but I had little idea of its extent. After a slight investigation, and a gathering up of various notes, I began to think it would take a good sized volume to give a clear and comprehensive idea of it. Since then I have come to the conclusion that it would require a library to adequately set forth the mysteries of reproduction in plant life and the amazing intricacies involved in the very numerous methods adopted for distributing the seeds abroad.

At the first blush one would not think there were likely to be many ways for a flower to transmit its pollen to the right quarter. But in point of fact every species of flower has some speciality of its own, always quite effective, and arranged with an ingenuity that compelled Darwin to cry out, "The more I study Nature the more I see that she is infinitely ingenious in arranging slight, so-called accidental, differences for the plant's benefit, and that, in fact, these ingenuities transcend incomparably the most fertile imagination that the most imaginative man can suggest with unlimited time at his disposal."

This you will admit is remarkably strong language, and when we consider it is applied to our everyday plants and their flowers, which we have for ages kicked hither and thither, and thrown over the wall without an idea that there was any particular mechanism concealed on their persons, it is humiliating, and shows very conclusively indeed how blind these clever bipeds, known as human beings, really and truly are.

The Chelsea philosopher, Thomas Carlyle, was even nearer speaking the truth than he thought he was when he classed us as mostly fools. We go chattering clumsily through a world of beauty, more than artistic, and see little or nothing of it, just because we are immersed and submerged in our own little selves.

The scraps of information I have to give are very scrappy. There is no attempt at scientific

arrangement, no sort of sequence in them—I give them as I came across them, or picked them up.

Some day another Darwin will arise and give us the evolution of plants in full, and astonish the world quite as much as the original Darwin did. Several good and daring attempts at this have been made already. A series of delightful papers appeared, I think, in "Knowledge" some years ago, but a comprehensive pronunciamento is coming, and soon, for the times are ripe for it.

We will begin with the Spotted Orchis. In this flower the stem supporting the pollen bag has its base in a disc, beneath which are two walls of very sticky matter. A mere touch from the proboscis of an insect, if it be the right insect, and things are all ready, causes a spasmodic, electric, or mechanical rupture of the membrane enclosing this sticky matter, and it adheres to the insect, which then elopes with the pollen bag and leaves the flower. By this time the sticky matter is setting like so much cement, and by some wondrous arrangement the pollen bag, which at first sticks out at a right angle, changes to an acute angle by the contracting of the disc, and then the insect can enter another flower, leave the pollen it is carrying at the right place, and depart with another pollen bag.

The pollen bags thus carried off always fall forward, never backward or sideways, for if they did not the insect could not enter the next flower. The insect, again, must alight in the right place to get at the nectary, which is a small vessel of honey. The insect probably has no idea that it is being made use of. The honey is there, it can smell that, and goes for it, and the plant clearly knowing all about it so arranges its nectary that there is the right amount of time to load it up with the pollen before the insect succeeds in getting the honey.

In the Orchis pyramidalis, the disc in which the stem carrying the pollen bag has its base in the shape of a saddle, which grasps the intruding proboscis, and undergoes various changes of position until the saddle clasps tighter and tighter and curls inwards, so that within eighteen seconds it looks like a solid ball. In this case two pollen bags arrange themselves so as to insure the pollen being affixed to the sticky mass in the next flower. The insect cannot get its proboscis in askew; if it could the saddle-shaped disc would not act properly, and the operation would end in failure.

When all is ripe in this flower you can impose upon it with a bristle. Apparently, it can tell a bit of wire or a needle, and will not act; but when Darwin got a bristle and inserted it the saddle gripped, and out came the pollen bag. A friend of mine says he succeeded with a thin programme pencil sharpened to a fine point. Inserting this in the bell of the field Orchis he, on withdrawing it, saw it covered with pollen, which in forty seconds was ready for its work in the next flower, only the programme pencil was wingless. At first the pollen adhered so fast that it could not be got off easily; but after a lapse of time needful for the bee to do its work, the cement dried and lost its elasticity. Another curious thing about the Orchis pyramidalis is the fact that it manages to attract visitors both day and night; the day visitors by the bright purple colour, the night visitors by a curiously foxy smell.

The moths fertilising these flowers do not always gain by the work they do. Greed here, as elsewhere, sometimes overshoots the mark. Darwin saw one with eleven pairs of these pollen bags attached to its proboscis, and thus loaded it could enter no other nectary. It almost seems as if Nature were thinking more of the flower than the insect. How the latter managed to accumulate so many collars and ruffs is not easily imagined. Darwin, however, found no honey in the nectaries of these flowers, and Krunitz came to the conclusion that this Orchid was just trying on a small swindle, and getting the insect to come on a false pretence. Darwin is of opinion that the honey is there, but better concealed, so as to detain the moth in search of it for the requisite time. He found several cunning arrangements in other flowers.

In cases where the matter is sticky enough to hold the pollen mass the nectary is easily reached, there being no benefit in keeping the insect waiting. Why the flower could not, or did not, always arrange things thus requires a considerably greater amount of explanation than I am able to cope with.

The Bee *Ophrys* Orchid is a surprise in all respects. It looks like a bee (just as a Spider Ophrys is like a spider and the Fly Ophrys like a fly), but why it looks like a bee requires some explanation, and why it provides for self-fertilisation still more. Self-fertilisation is the one thing that the greater part of the ingenuity displayed in plant life is intended to prevent; but in this queer little Orchid it is as clearly meant. The pollen bags are so arranged that a gust of wind sends the drooping head of the bag against its own disc. The stem is flexible, and keeps bending in the right direction till the wind rises and completes the work. Darwin says he never knew a case when this plant did not fertilise itself, but he was also quite of the opinion that it was occasionally fertilised by foreign pollen, or it would have perished.

The question of self-fertilisation is a curious one, inexplicable indeed in our present state of knowledge, or rather present state of ignorance. There is abundance of evidence that Nature intends self-fertilisation as a last resort to carry on the species when cross-fertilisation is not achieved. In the Forget-me-not, for instance, the pistil, or female organ, is longer than the corolla stamens, so that an insect alighting with foreign pollen on its body comes in contact with the first, but the corolla and stamens gradually grow up to the pistil, when self-fertilisation is inevitable. In some cases this is impossible, the pollen having no effect, or even a poisonous one, on the stigma of the same flower. Plants, the result of cross-fertilisation, are stronger and larger than those which result from self-fertilisation.

Sometimes the visiting insect gets the pollen attached to its face instead of the proboscis—all depends on the position of the sticky matter. In one case the insect alights on the lip of a flower, which immediately gives way and sinks so low that it seems as if the pollen could not be got at. But when the insect gets inside, the lip of the flower goes back in its place, and in such a way as to insure its brushing the pollen off. In the Marsh Epipactis, the insect, in backing out, touches the broad end of an anther, which then releases the pollen as if there were a spring at work. Darwin in this case tried a long time to unlock the pollen with a feather, but till he touched this particular anther it remained quite fast. This explained why the lip fell when the insect alighted on it. If it had not done so the insect going in that way, instead of coming out, would have brushed off the pollen where it was of no use.—(*Paper read by* Mr. W. PICKARD *at a meeting of the Sheffield Chrysanthemum Society*)

(To be continued.)

PRUNING GOOSEBERRIES AND CURRANTS.

VARIOUS methods of pruning bush fruits are adopted, both good and bad, but as regards the Gooseberry the effects of ill-treatment are not always apparent to the untrained eye, at least for several years, when the value of the plant has been materially decreased. This plant will endure much rough treatment and yet produce its annual crop of fruit. I have seen bushes pruned with shears into rounded mop-heads, still there was fruit to be gathered, though difficult to get at. On the other hand I have known bushes practically left to themselves, no systematic or other pruning being attempted, and berries were had, but in diminishing size and quantity, year after year after the first vigour of youth was passed. When we possess a plant that will endure so much it ought to pay for better treatment, and in fact the Gooseberry responds most readily when subjected to judicious methods. It should not be a question how much it will endure, but how far we can improve it by the best attention. This, I know, is the way in which all true gardeners regard every plant under their charge, but there are some who have not their hearts in the work, and others who are beginners, and so we always find a proportion of carelessness or mistakes that need rectification.

The present is a suitable time for pruning bush fruits, and it should be equally seasonable to relate our experience, and submit observations for consideration. First of all, a word of caution may be given to the inexperienced who may be purchasing Gooseberries, because it has a direct bearing upon the subject we are about to discuss. Whatever age the bushes may be, see that the stem rises several inches clear of the ground, and that there are no buds below the soil level. Why so many Gooseberry cuttings should be made without the removal of the lower buds it is difficult to imagine, for

the extra labour in the proper preparation is slight. Unfortunately, however, many thousands of these undisbudded bushes are sent out annually, with the result that endless labour is caused for which there is no return. I will give the nurserymen the credit of believing that in their own practice they do not follow such careless methods, but in the demand for some sorts their own stocks are frequently exhausted, and they have to procure plants from other sources where due care has not been exercised. It seems a simple matter to dwell upon at such length, but I have been a sufferer through neglect in this matter, and perhaps others may profit by my experience. If there are only a few dozen plants to attend to, it is not a very serious matter to remove the suckers that are constantly arising from the base, but when they number many thousands it practically means that it considerably increases the cost of pruning, and is an absolute loss. Two varieties that are the worst in this respect when not disbudded are Whitesmith and Lancashire Lad; I have seen as many as ten vigorous suckers, each 1 to 3 feet long, from the roots of these, and they are very difficult to remove thoroughly without injuring the roots or stem of the plant. It is really impracticable to cut them off close enough to prevent further growth, and consequently every year the trouble increases. They are always stronger than the central portion of the bush, and in consequence withdraw much nourishment from the fruit-bearing branches.

It does not matter with regard to Black Currants if there is a free growth of shoots from the base; in fact it is an advantage, as it provides a means of renewing the bushes, and compensating for the loss of branches which frequently occur in those plants, but it is altogether different with Gooseberries. The farther the branches are from the ground the more convenient they are at fruit-gathering time, and with some of the spreading sorts the shoots from the base will lie flat upon the soil obviously useless.

Summer pinching of lateral growth in the Gooseberries is to some extent advantageous when it can be done sufficiently early and performed thoroughly, but unfortunately it requires attention at a time when there is much other work in hand, and in consequence in large plantations is only partially carried out or omitted entirely. When the growths from the main stems are shortened early to an inch or two, it undoubtedly serves to concentrate the strength of the bush into the fruit-bearing parts, and reduces the labour of autumn pruning. As a garden practice and for small plantations it is most desirable, but in my own case, and I imagine in many others similarly situated, the early summer labour is of more importance and value in other directions.

The chief considerations in pruning established Gooseberry bushes is to keep them open and free from crowding growths, which are very apt to arise in the centre of the bushes. If they were started as two or three-year-old plants, and were judiciously cut-in to insure due furnishing of the bush, they should have in the second year from planting from six to eight main branches, radiating and ascending from the centre of the bush. These should not cross or approach near each other, and though it is difficult at times to form an ideal plant, it is always possible to prevent crowding, and this will have a great bearing upon fruit development. The side growths from these are shortened to two or three buds, or at the densest part of the bush removed altogether; or if summer pinching is done they will scarcely need any attention, except in some cases a little further shortening.

The points of the main branches need to be reduced in proportion to the strength of the bush and the variety. I make a difference in the treatment of such varieties as Crown Bob and Whinham's Industry for instance. In the former, which produces more slender, relatively weaker shoots, the points are reduced to 2 or 3 inches from the previous season's wood, while Whinham's has the points left 4 to 6 inches long, or in some cases more than that. Even then we frequently remove 8 or 10 inches of growth. After a season or two's treatment in the manner described, the wood that is more than a year old is studded thickly with fruit buds over the whole length.

One other matter should be pointed out, and that is with respect to the buds to which the main branches are cut. All erect-growing varieties like Whitesmith are pruned to a bud pointing outwards, but with some of the more straggling growers it is needful, more especially as regards the outer branches, to prune to an inside or upper bud. When a branch is dropping towards the soil and it is cut to a bud on the under side, the extension is continued in the same undesirable direction, and it may be necessary to cut the whole shoot away. Simple as this practice is, if consistently followed up it effects the general form and usefulness of the bush most satisfactorily.

The same general principles are applicable to Red Currants, but these plants do not give nearly so much trouble after a few seasons' attention. The constant fruit bearing keeps them within bounds, and beyond a judicious shortening of the main branches, and reducing the laterals as with Gooseberries, they take up little time. The fruit-bearing wood is precisely the same as in their thorny relative—*i.e.*, that over one year old, and the branches of well treated bushes may be seen now closely studded with buds. Black Currants have already been incidentally referred to, and it is only necessary to add here that we endeavour to retain all the current season's growth, and to replace old shoots by new ones where possible, for the greater part of the fruit is borne on the young wood. It is as undesirable to have a Black Currant crowded as either the Red Currant or the Gooseberry, but the labour of keeping the former in proper shape is very small compared with the others.—An Old Grower.

NOTES ON BULBS.

Having in two instalments, the last of which concluded on page 340, dealt at some length with the culture of Hyacinths in pots, we may now pass on to other bulbous flowers, which, if not quite so imposing, are equally as useful. Bearing in mind that the same cultural details are in the main suitable for all, it is not now proposed to go into the individual treatment of each. Let the same system be adopted for those that are to be named as was recommended for the Hyacinths, and the chances of success will be excellent. Where a slight variation from those lines has been found advantageous it will be noted, but it is now proposed to deal principally with varieties that have been found the most generally satisfactory. Of course it will be remembered that pot culture is still under consideration, and that it is for this purpose the varieties are named.

Tulips.

These gorgeous flowers are popular with almost everyone, and they can be successfully grown in places where other plants might prove a failure. So far as our experience goes, and we grow some hundreds every year, they differ from Hyacinths in one respect to a marked degree, and that their partiality for water. Of course Hyacinths want large quantities when they are advancing into flower, but the Tulips require more. Personally, I am of the opinion that the cause of these bulbs failing to flower, as they do occasionally, is insufficient supplies of water, and I should much like to know the experiences of other growers on the point. Beyond, then, giving more water, the bulk of our Tulips are treated precisely the same as Hyacinths. Though a few are forced, the major portion of the bulbs are grown for the embellishment of the conservatory in the spring months, for which purpose we find them invaluable.

Those that are grown for early flowering, and which are forced, are never potted in the first instance. Instead of this, the market grower's system of growing in boxes of cocoa-nut fibre refuse is adopted until the plants are well advanced in bud, when they go into the receptacles for perfect development. We have ornamental vases that just accommodate four bulbs, and by selecting those with buds at a similar stage they all flower at the same time, and are thus more effective. It involves a little more labour perhaps, but it is more than repaid at flowering time. With the later ones, which are not used in pots for room decoration, we are not so particular, though we think sometimes that even these would be worth growing in the same manner. For forcing purposes we grow three varieties only of single Tulips, which are the red and yellow, the scarlet, and the white Due Van Thols, the second named being the greatest favourite owing to its bright cheery colour.

Of the Dutch single Tulips we usefully confine ourselves to about one dozen varieties, of which Ophir d'Or, Scarlet Pottebakker, and the white Van Vondel are grown by far the most extensively. For years we have made a feature of these, and never once have we failed to score a success. Others have been tried, both new and old, but we cannot yet find a trio to surpass them, all points considered. Other favourites are Vermilion Brilliant, Proserpine, Le Matelas, Royal Standard, Bride of Haarlem, Keizers Kroon, Joost Van Vondel, White Pottebakker, and Van der Neer. Those that grow tall and produce large flowers, such for example as Keizers Kroon, have a very slender stake placed to each bulb so as to maintain the spike in its proper position. Of single Tulips we made it a rule to place three bulbs in in each 4½-inch pot, and it is occasionally a tight squeeze with the large bulbed varieties.

To double Tulips for pot culture we are not particularly partial, but we grow a few for the sake of the variety they impart to a collection. The red and yellow Tournesol we find consistently good, as also is the old Imperator Rubrorum. Then there are La Candeur, Mariage de Ma Fille, Matador, Murillo, and Salvator Rosa, with each of which we have done splendidly at times. Occasionally others have been added or substituted, but for the main display we depend upon about half a dozen varieties that we know to be reliable. It is almost always imperative to stake the flowers of the double Tulips on account of their great weight, and needless to say it must be done carefully, or the good appearance of the pot of bulbs will be absolutely destroyed. With

these, as with single Tulips, it is essential that abundance of water be supplied during the growing and flowering period.

Crocuses.

Useful as these are for certain purposes when grown in pots, it is in the open ground, or in window boxes that they are the most highly appreciated. However, we make quite a little feature of them in 3½-inch pots, in which we grow about 500. The whole stock is potted at one time, and when they are in flower we stand them about in the conservatory amongst other plants, and they form a change that is always admired by visitors. Their beauty is of the lowly kind as compared with that of Hyacinths, but personally I am extremely fond of them. We grow only four varieties in distinct colours, and generally have the large yellow, Sir Walter Scott or La Majestueuse, with a good blue and a white selected from one of the bulb merchants' catalogues, and we never purchase the same varieties of these two years in succession. In cultivating Crocuses we subject them to precisely the same treatment as the Hyacinth.—H. Rose.

RUDBECKIA GOLDEN GLOW.

With your remarks on page 363 concerning the merits of this as an ornamental plant I quite agree, but it is not a very new plant to English gardens. It was introduced from North America nearly twenty years ago by Messrs. Smith of St. John's Nurseries, Worcester, and offered in their catalogue by the name of Rudbeckia lævigata; thence it came into my garden, and though it does not increase fast, it has had time to find its way into most of the cottage gardens in the parish.

I sent the plant some years ago to Kew for identification, and it was there considered to be a variety of R. laciniata, though it differs in many respects from the type of that species. Asa Gray, in his "Flora of North America," considers R. lævigata of Pursh to be a dwarf form (a foot or two high) of R. laciniata, though he does not seem to know the variety. Our plant does not fit any Rudbeckia described by Asa Gray. Perhaps it may be a hybrid, say between R. laciniata and R. pinnata, or R. maxima. This seems more likely, as I have never been able to find or hear of a fertile seed on the plant, whilst R. laciniata ripens seeds freely in English gardens. It was figured in "The Garden" as "R. nitida," a species the characters of which it will not fit, though that, too, has a var. lævigata (*Nuttal*), said to be distinct from the R. lævigata of Pursh.

The provisional name Rudbeckia Golden Glow is safer than a conjectural specific name, but I think I have seen it in Barr's catalogue called Autumn Glory, and it would be well to obtain consistency in these fancy names. The flowers last remarkably long, often well into November, and few plants make so large a show from so small a base; it has also the merit of flourishing for many years in the same spot without interference.—C. Wolley Dod, *Edge Hall, Malpas.*

[Thus does the good influence of a true flower lover spread and brighten the cottage gardens around him.]

HINTS ON SPRING BEDDING.

The time has already arrived for the beds to be cleared of their summer occupants, and where they are to be filled with bulbs and plants for the spring display not one day should be lost in setting about the work. This is most important for more reasons than one. In the first place, where frost has destroyed tender plants, such as Begonias, Alternantheras, Celosias, and Cannas, with others, they will have a very untidy appearance. Secondly, the weather is at present very favourable for the work, and we cannot expect better; the soil is also warm, and the plants will take to it quickly, and soon establish themselves.

Perhaps the description of a few simple, but effective, beds of last year might be interesting and useful to some of the readers of this Journal who cannot go into elaborate and expensive planting. Some beds planted with Myosotis dissitiflora, and a good sprinkling of Queen Victoria Tulip (white), were very charming; others contained Wallflower Tom Thumb (golden), with Keizers Kroon Tulips, and all were also much admired.

A large bed, filled with the Money Plant (Lunaria biennis), Doronicum plantagineum excelsum, bold groups of dark and yellow Wallflowers, with wide bands of Hyacinths and Tulips, and finished with an edging of Dactylis glomerata variegata and red Daisies, was fine.

Smaller circular beds were planted with yellow Polyanthus and blue Hyacinths, others with red Polyanthus and white Hyacinths. These were very effective.

We have already stocked many of the beds in the following way. Large circular beds with golden Myosotis and scarlet Tulips (Artus); white Pansies and blue Hyacinths; purple Pansies (Cliveden Purple), and white Hyacinths; others with Dielytra spectabilis, Cloth of Gold Pansy, Duchesse de Parme Tulip, with a broad band of Aubrietia græca.

I trust the above simple hints may be useful to those who are on the look out. There are probably some who are about to do their first spring beds, and those I have described above I can strongly recommend. The bed planted with Dielytra I expect to be very effective.—A.

Chrysanthemum Leaf-Rust.

On the 21st of August, 1897, a disease appeared on Chrysanthemums at Maidenhead, and specimens were forwarded to the Editor of the *Journal of Horticulture*. These were examined by me on the 26th of that month, with the result that a reply appeared in the issue of September 2nd, page 231. The infection was attributed to an attack by the leaf-rust fungus, Trichobasis Artemisiæ, *Berkeley*. I had an impression of "rust" having been before noticed by growers of the "autumn queen," and hence the remark of its being "a rather uncommon parasite on the Chrysanthemum, but destructive when it does occur." For the purpose of further investigation I obtained leaves of the common Mugwort (Artemisia vulgaris), as this is the native host of the Chrysanthemum mildew (Oïdium chrysanthemi), and on comparing specimens considered the forms of leaf-rusts found on both identical, namely, Trichobasis Artemisiæ.

There the matter rested until September 18th last, when I examined specimens submitted by a large grower in Kent, magnificent, large, thick, leathery, deep green leaves (barring brown spots) seriously infected by the rust fungus, the pustules being much larger than commonly found on Chrysanthemums.

On October 9th, 1897, I had occasion to examine specimens from Somerset—a whole boxful, forwarded by the Editor—of splendid leaves, but containing myriads of spores of the rust fungus. The plague thus exists in Kent, Somerset, and Berkshire. Very good (or bad) examples of it have also come from the Isle of Man. The grower in Berks deserves thanks for first drawing attention to what may be termed the Chrysanthemum epidemic, which may now be referred to.

In the illustration (fig. 57), at *A*, is shown part of the under side of an infested leaf of a Chrysanthemum, large, deep green (where not affected by the fungus), and apparently very healthy but for certain dark brown spots (*a*), which varied in size from a pin-point to one-sixteenth, one-eighth, and a quarter of an inch in diameter. In some parts, especially near the midrib, the whole surface of the leaf was covered by a dark brown, almost black, powder, due to the pustules running together, rupturing the lower epidermis and liberating the spores. This is shown at *b*, the portion of leaf natural size. There was also a few pustules on the upper surface of the leaf, very bold, one-eighth to a quarter of an inch in diameter, showing that the germinal tube from a fungus spore can pierce the upper as well as the under epidermis of the leaf.

Selecting one of the ripest and blackest pustules I examined it with a lens, said to enlarge 260 diameters, for the purpose, if possible, of finding teleutospores – the resting or winter stage – or rather the mature stage of the fungus, and got a variety of forms, fairly represented at *B—c*, uredospores = Trichobasis (Uredo) chrysanthemi; some almost round and concatenate (*d*), but all uredo or summer spores, one (*C*) pushed a germinal tube (*e*), and a small teleutospore (*D*). A poor thing, but sufficient to induce further search. After much scraping, section taking, and long and close observation, I came across the full-blown Chrysanthemum leaf-rust fungus, Puccinia Chrysanthemæ, shown at E.

It first appeared one-celled, a Uromyces, but after a time, hardened up as represented, two-celled—a Puccinia. The rust, however, is a fac-simile of the Mugwort leaf-rust, Trichobasis (Uredo) Artemisiæ, and seldom anything else, for the Puccinia form, P. Artemisiæ, is about as difficult to find as the teleutospores on Chrysanthemums. It was finer, however, and I consider an evolution of the Mugwort leaf-rust, hence its being given here as a distinct species.

To verify the matter I sought for more leaf-rust on the common Mugwort, but all the old leaves had collapsed from the attacks of the parasite, and on a young leaf only (*F*) could I find it. I found, however, some old leaves with sere pustules. The pustules on the young leaf were almost black, of needle-point to pin-head size, and one gave the spores shown at *G* = Trichobasis (Uredo) Artemisiæ, all the spores roundish or oval, being uredo or summer ones.

The old leaves proved very unsatisfactory, the teleutospores had fled, if there had ever been any, but I made a last effort and discovered the form shown at *H* = Puccinia Artemisiæ – the resting or winter (teleutospore) or final stage.

I next examined the rust on the common Thistle (Carduus vulgaris) Trichobasis Cichoracearum. The pustules are larger and brown, not nearly so black looking as those on the Mugwort. They are much like those on Chrysanthemums, even the small, as shown at *h*, and run together as at *i*. The uredospores (*J*) and the teleutospores (*K*) still more so. This is the fag end of the Thistle parasite, and the Mugwort parasite is also shown at its worst as regards the uredospores. I have given the three as they were found on October 9th, 1897, and I think no one will deny the Chrysanthemum leaf-rust fungus is much the better, even if not going along with me to the evolution – a new form—namely, Trichobasis chrysanthemi.

We now pass to the first specimen seen in 1897. It was from Maidenhead. Shown at *A—E* indicates the prime of Trichobasis (Uredo) chrysanthemi. The fungus plant likes good fare, loving the large, thick, leathery, deep green leaves. Some may say the Chrysanthemum so

highly fed has invited disease, but the parasite did not begin on the fine leaves, but on the weaker from the Royal county. See its fac-simile at *L*, under side of the leaf, natural size. It is just half the size of the leaf of the specimen from Somerset and from Kent. One has leaves little thicker than ordinary writing paper, and the other stout, elastic, strong, and tenacious as shoe leather. So much for robustness as the predisposing cause of attack.

The fungus, Chrysanthemum leaf-rust (Trichobasis chrysanthemi), produces dark brown pustules on the under side of the leaves of the Chrysanthemum sinense vars. (most on the Incurved sections), as shown at *L*, some small (*j*), others larger (*k*) and isolated, not a few in groups (*l*), and often becoming confluent (*m*). The pustules contain a number of spores (*M*), very dark brown or nearly black, echinulate (very short bristles), with always one (*n*) transparent spot, sometimes two (*o*), free, attached at first by a short peduncle (*p*), and caducous (spores falling very early). In some cases the spores are, or appear, concatenate (chained), as shown at *q*. All the spores are uredo, or summer ; at least, I only found the miserable apology for a teleutospore (shown at *r*) on August 26th, 1897.

These uredo or summer spores germinate at once on a clean, healthy leaf of a Chrysanthemum (almost every one on the under side) with the greatest freedom in presence of moisture, but seem baffled on the upper side of the leaf, either by the sunlight or dryness. Some spores there do not even attempt to grow, but appear to thicken their outer coat, becoming as if warted, and losing the transparent spot, getting round, and apparently capable of retaining vitality for a considerable time. I have some collected on August 26th now (October 11th) quite sound, and these, when placed on the leaves from Somerset with a little moisture on them, pushed germinal tubes and bored right into the leaves without the least difficulty.

The effect of the entrance into the leaves of the germinal tubes of the fungus spores is to produce the pustules before mentioned on the under side, these being at first pale green, then yellowish, afterwards light brown, getting darker as the spores form, and growing outwards push through the destroyed epidermis. The germinal tube once inside the tissues divides, forming mycelium hyphæ very densely, which push in the intercellular spaces of the cells, abstract their contents, and take their place. The hyphæ form a perfect net of threads, and push out growths so plenteously as to render the spores very crowded, squeezing each other into odd shapes, the younger pushing off the heads of the older in order to take their place. Thus the spores are shed in myriads, and it is only a question of a Chrysanthemum leaf being seized for the work in new generations to proceed with astounding rapidity.

The effect is to destroy the lower substance of the leaf to the extent of the pustules, such leaves becoming brown and dying more or less as the tissues are affected right through, pale spots appearing on the upper surface, as shown in part of a leaf at *N*, these being at first pale green, afterwards yellow, and then brown. The plants are weakened in consequence of the attack, and if the parasite is left to run its course unchecked they may be ruined.

How the teleutospores behave I do not know ; but as gardeners cut off the old Chrysanthemum stems in good time to get strong suckers, by burning these stems the resting spores are consumed. There are very few of them. The fungus can, however, be continued without them. The uredo form of many Puccinia certainly lives, especially on Mugworts and on Thistles, over the winter, and is more likely to do so on Chrysanthemums protected from frost, which means that the uredo stage of the fungus may live on the cuttings.

This brings us to the question of battling with the foe. Kill the spores. Badly infested plants should be burned, and others syringed from tip to toe with sulphide of potassium, ½ oz. to a gallon of water, or permanganate of potash, 1 oz. to 3 gallons of water, laying the plants on their sides, and doing the work thoroughly, so as not to leave a spore unreached. The suphide smells nauseously, and discolours paint ; the permanganate discolours the flowers.

Bordeaux mixture at quarter strength should also be mentioned as a preventive and remedy in early stages of attack ; sulphate of copper, 1½ lb. : best chalk lime, freshly burned, light lumps, 1½ lb. ; water, 22 gallons. Dissolve the sulphate in 1 gallon of cold water in a tub or earthen vessel. Slake the lime in another in a gallon of water, and when cold pour through a coarse bag into the sulphate of copper solution slowly; stir, then add the remainder of the water. Apply with a spraying apparatus, wetting the under side of the leaves particularly, but all parts of the plant. It will kill the spores on which it rests and enter the open pustules, but not those unruptured, therefore repeat occasionally. It is a mild and safe application.

There is the question of cuttings. To make sure they are clean dip them before insertion in the weak Bordeaux mixture advised. This will coat them with a thin film of the poison, and while there no fungus can push its germinal tube and take possession of the leaves. "What a bother," some will say. Well, the enemy has come, and should be conquered. The advertised fungicides containing sulphate of copper can always be had. Use them in good time, and repeatedly, and their value will be proved in vanquishing this insidious enemy of the Chrysanthemum—G. ABBEY.

SPECIMENS of diseased Chrysanthemum leaves were recently submitted by a New Jersey florist to Dr. Halsted for examination and advice as to the course of treatment to be pursued. His reply is as follows : —

"There is a genuine rust upon the cultivated Chrysanthemum sent by the correspondent, and it probably is the Puccinia tanaceti, *D.C.* There is doubt as to the species, because only the uredospores have been found upon the leaves examined, but these agree in size and shape with those of P. tanaceti, and furthermore this species is found upon a species of Chrysanthemum as shown by an herbarium specimen.

"The florist has written me that he may lose his whole crop from this rust. It appears upon the foliage in small brown spots, which consist of heaps of spores borne upon the tips of threads that have pushed through the skin of the leaf. The Carnation rust is not unlike this in general appearance, but the final spores are very different, provided the Chrysanthemum rust proves to be as suspected.

"Growers of Chrysanthemums should look to their plants, and if any find the rust it ought to be dealt with summarily, for the enemy is a serious one. The rust fungus sends its threads all through the plant before the spores are produced, and therefore spraying may not prove a satisfactory remedy for it. All affected leaves should be picked off and burned.—BYRON D. HALSTED, *Experiment Station, New Brunswick, N.J.*" (in "American Gardening.")

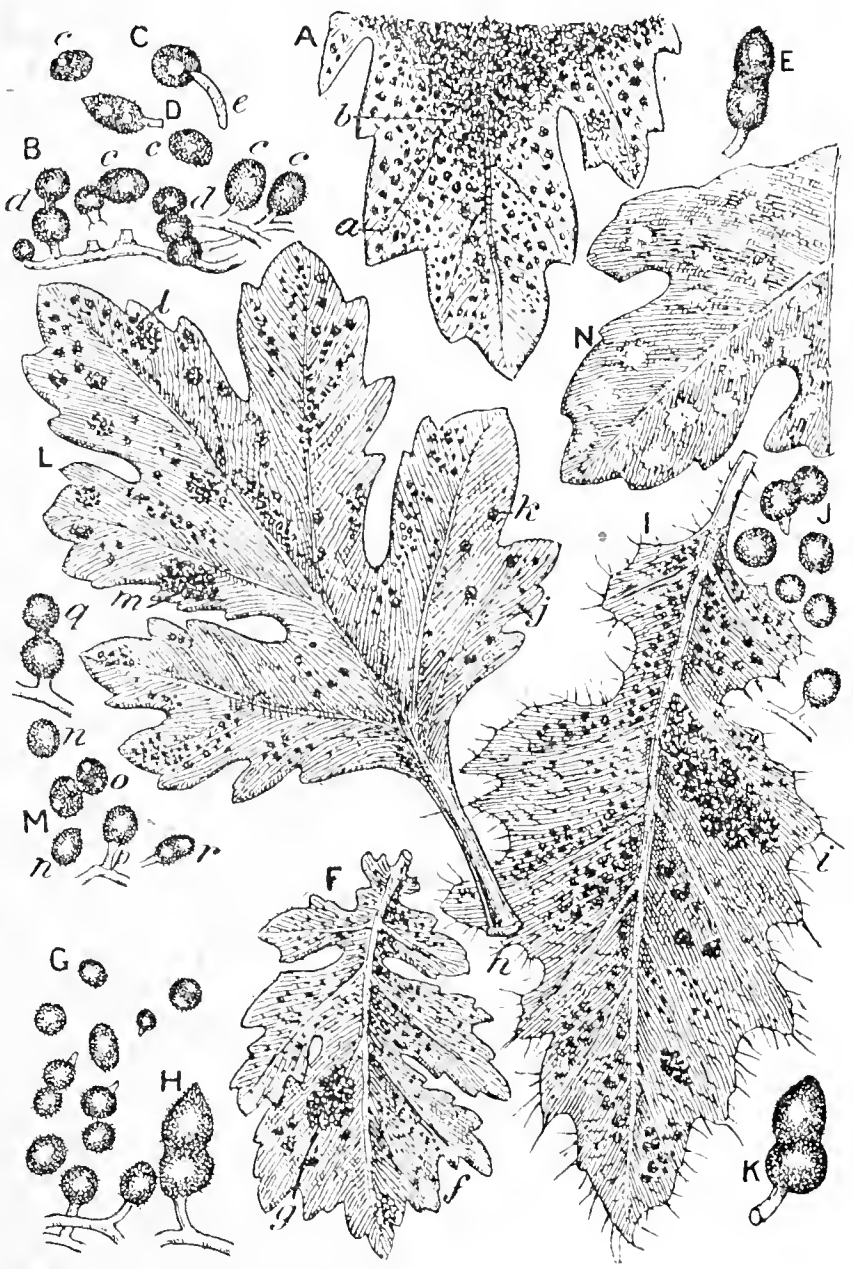

FIG. 57. — CHRYSANTHEMUM LEAF-RUST FUNGUS [TRICHOBASIS (UREDO) CHRYSANTHEMI, WITH FINAL STAGE — PUCCINIA CHRYSANTHEMÆ, AND OTHER RUSTS.]

References.—*A*, Part of affected leaf of Chrysanthemum (October 9th) ; *a*, small pustules of fungus ; *b*, pustules confluent or run together. *B*, Trichobasis (Uredo) Chrysanthemi spores ; *c*, usual form ; *d*, concatenate type. *C*, summer spore germinating ; *e*, germinal tube. *D*, teleutospore found in first pustule examined. *E*, mature teleutospore = Puccinia Chrysanthemæ. *F*, young leaf of Artemisia vulgaris (October 9th), showing : *f*, small pustules ; *g*, pustules become confluent or run together. *G*, uredospores = Trichobasis (Uredo) Artemisiæ. *H*, teleutospore = Puccinia Artemisiæ. *I*, small leaf of Carduus vulgaris ; *h*, pustules of root fungus ; *i*, pustules confluent. *J*, uredospores = Trichobasis (Uredo) Cichoracearum or Heraclei. *K*, teleutospore = Puccinia Cichoracearum. *L*, Chrysanthemum leaf (August 26th) : *j*, small pustules ; *k*, large pustules isolated ; *l*, clustered pustules ; *m*, pustules confluent. *M*, uredospores from pustule ; *n*, spores with transparent spot in centre ; *o*, spores with two spots ; *p*, spore on peduncle ; *r*, miniature teleutospore, the uredospore = Trichobasis (Uredo) Chrysanthemi. *N*, part leaf of Chrysanthemum, showing spots on upper surface, and corresponding to pustules on the under side. All the leaves or parts natural size, and all the fungi enlarged 260 diameters.

[As will be seen by the above record, attention was first called to the Chrysanthemum rust fungus in the *Journal of Horticulture*. Mr. Abbey's illustrations are from actual specimens found in the different leaves examined. Is the American parasite the same under a different name ?]

Preventing Mildew and Damping.

Chrysanthemums, when brought into the structure in which they are to flower, require to be disposed in such a manner that the plants will receive plenty of light, air, and a cool position to stand upon. Light is essential in order to retain the healthy colour of the leaves, for while they remain green and carry out their important functions a steady and certain development will take place in the perfecting of the blooms.

Air, constantly renewed, cool, and fairly moist, helps the plants to maintain the sturdy condition which favoured them previously. These conditions will also prevent mildew making its appearance on the leaves, or at least check its spread if it has originated, especially with the assistance of dustings of sulphur upon the affected parts.

When the atmosphere is moist with an excess of moisture from prolonged rain or fogs it is well then to exclude its too free admission. I would not recommend the house being entirely closed; but apply a little artificial heat, causing the air to be set in motion, whereby the too moist atmosphere may be made drier, and therefore light and buoyant. The deposition of moisture on the tender florets of flowers is not harmful provided it does not remain upon them too long. That is the mischief, and also the accumulation of moisture at the base of the florets. The latter is frequently the sole source of damping. The larger the flowers the greater the danger; so when large and valuable flowers are developing a thorough drying of the structure once a day must be beneficial, and not less needful when the flowers are fully open. When the blooms are half developed cease applying manure water. Excess of stimulants at this period does not prove helpful, but the reverse.

The closer the blooms are to the glass the more liable are they to fluctuations of temperature and the consequent deposition of moisture upon them. The best way to avoid the danger is to maintain as far as possible a regular and even temperature, so that excessive cooling may not cause the watery vapour to become condensed upon the delicate tissues of the flowers.

Careless watering and the needless wetting of floors and stages give rise to more moisture than is good for the blooms when evaporation is slow. In common with other growers, I have always found it to be a safe plan to maintain a constant circulation of air with a little heat in the pipes, and all classes of growers will find the practice beneficial. —E. D. S.

Chrysanthemums from Rothesay.

The collection of early-flowering Chrysanthemums grown by Messrs. Dobbie & Co. in their Scottish Nursery is an extensive one, and comprises the majority of the leading varieties in cultivation. The firm recently sent us a box containing upwards of three and a half dozen varieties, and, needless to say, several of them were of great beauty. The flowers were of good average size, and the colours, in all instances, were well developed. The utility of this section of the Chrysanthemum family is, we think, not sufficiently recognised. They grow and flower in town almost equally as well as in country gardens, while they require neither very special soil nor any particular position. Though they soon begin to feel the effects of frosts, they do not succumb to the first that comes, as is proved by the fact that the night previous to the flowers that reached us from Rothesay being cut, 5° of frost were registered. If anyone were to see a collection such as Messrs. Dobbies', they could not but admit the beauty and the utility of the September and October flowering Chrysanthemums. Space does not permit of our naming the varieties sent, but they comprised new and old ones of the best quality only.

Chrysanthemums at Barford Hill.

Aided by the beautiful weather of the last few weeks Chrysanthemums are opening their flowers rapidly, and in the majority of instances satisfactorily. Those who look upon the flowering period of the "autumn queen" as a time of keen enjoyment will, I think, this season be able to "revel" in a veritable "feast of beauty."

Being in the neighbourhood of Barford Hill, near Warwick, a few days ago, I made a point of calling on Mr. R. Jones, who has generally something good to show at all seasons. I soon found that the Chrysanthemums were looking well, and that the collection, as usual, contained most of the new varieties worth growing, as well as such older ones as are not yet "out of date." Many strong plants with leathery leaves promise to give grand blooms. Among these may be mentioned Mrs. H. Weeks, Pride of Madford, Madame Gustave Henry (a beautiful white), Mrs. W. H. Hurley, Eva Knowles, Mdlle. Thérèse Rey, and Simplicity. The last named is a white flower of lovely type, which I fancy will prove the best among the many fine white varieties we now possess. Mrs. W. H. Lees, Thos. Wilkins, Mutual Friend, Lady Byron, Souvenir de Petite Amie, and Graphic were old friends in good form. Octoroon—blood red, reverse side of petals lighter in colour—is a telling variety, one that takes the eye at once; Mr. J. Shrimpton, a golden buff flower with crimson stripes, is good in every way, and is also quite a novelty; Amiral Avellan, Modesto, and Australian Gold form a trio of yellow varieties, which would be very hard to beat. C. W. Richardson, Red Warrior, Mrs. W. E. Palmer, Dorothy Seward, Mrs. Briscoe Ironside, Mrs. Chas. Blick, Milano, and Lady Hanham are all good comparatively new varieties, represented by substantial blooms.

The whole of Calvat's novelties for 1897 are growing by themselves, and promise to give something choice later on, if one may judge by the solid blooms of the only variety get in flower—this is Soleil d'Octobre. The other varieties are also advancing well. In the incurved section I noticed good blooms of C. H. Curtis, D. B. Crane, J. Agate, J. Fulford, and the various members of the "Queen" family. —Wanderer.

Sheffield Chrysanthemum Society.

At the monthly meeting Mr. William Pickard read a very instructive and interesting paper, the subject being, "The Intelligence of Plants and the Distribution of Seeds." The meeting was numerously attended. Mr. Pickard handled his subject in an able and efficient manner, and referred to many cases in which he detailed the beautiful, effective, and elaborate mechanism by which plants are fertilised, and by which they are enabled to scatter their seeds. He expressed his views at length on the wonderful and perfect laws that enable plant life to be constantly progressing and making advances towards perfection, full particulars of which may be obtained on reference to the essay of which the first instalment will be found on page 377.

The essay was greatly appreciated by the audience, who signified their approval by a very hearty vote of thanks to Mr. Pickard.

The monthly exhibits were for professional members' ornamental plants, when the species of plant life that supplies the "croton oil" and "dragon's blood" of commerce were in evidence by some of the more aristocratic members of their family, the most fortunate owners of the plants being Messrs. Thos. Morton and G. Smith for the first and second prizes, and Messrs. C. Scott and R. Agar being, in the Judges' opinion, equal, shared the honour of third prize. The amateurs, putting aside the ornamental for the useful, so far as the eye and the stomach are concerned, competed for Tomatoes, and produced some very creditable examples, with the result that Messrs. W. Green, P. Cox, and W. Donaldson secured honours of first, second, and third prizes respectively.

A number of applications for the benefits of the Society were made, and after being duly considered the applicants were enrolled on the list of members. Mr. John J. Newsham presided in his usual business-like way, and was awarded a vote of thanks for his services.—J. H. S.

Chrysanthemums in the North.

As the culminating point of interest in our own collections draws near we begin to find ourselves scarcely less interested in the prospects of the season and how it affects other growers. Last year I had the privilege of collecting notes on the subject from growers covering a wide area, and, so to speak, focussing them into view for the convenience of the readers of the "Journal." As showing the practical interest evinced in Chrysanthemums, the ready and full replies to inquiries and the cordial invitations would have provided copy to fill much more space than the Editor could set apart for one section of the country. If the gentlemen who so readily responded to my inquiries of last year will again favour me, at the same address, with a summary of the present year's prospects with any points on the habits of new varieties, and important details bearing upon the cultivation and results as affecting leading varieties, I shall have pleasure in again dealing with the matter to the best of my ability.

Compared with last year how far better or worse the blooms of the present season eventually prove, remains to be seen. Up to the third week in August the climatic conditions of the two seasons ran in parallel lines, both being characterised by a dry atmosphere and bright sunshine. Last year after the time above indicated, in the North we experienced one of the wettest and most uncongenial autumns on record, with especially moist atmospheric conditions, and without a gleam of sunshine to give us encouragement or lighten the prevailing anxiety as to the results.

During the present season the same conditions prevailed until showery weather came about the same time as last year, continuing for a few weeks, but again settling down, favouring us with a remarkably fine September and October up to now. Notwithstanding the unpropitious conditions for bud and bloom development of last year, the results proved far more satisfactory than was expected, all sections of Chrysanthemums producing at least average specimens. This teaches us the useful lesson that, despite the most uncongenial conditions of our autumn climate, the plant is able to assert its natural propensity to produce bloom with the dying year, and good blooms even, when given fine sunny weather up to the flower-bud-forming stage.

Reasoning on the same lines the present season should be taken as one giving us hopes of exceptionally good results, because in both its growing and bud-forming aspects it has proved, according to our present knowledge, to be one of the most favourable on record, with the possible exception that the effects of over-ripeness in some cases may intervene. If this forecast prove generally correct, the comparison of two widely different autumns following two summers practically alike in their effect on the growth of the plant, will no doubt furnish data as to the proper degree of wood-ripeness required for the production of high class bloom.

Although over-ripeness in the North may not be as common as it is in the South and West, the question of the proper degree of ripeness is of equal importance to growers, as being part and parcel of the same question wherever they may be situated. Observations by growers leading up to a concensus of opinion on this matter would be most interesting, and none the less valuable, if they were based upon the ruling principle that natural wood-ripening itself, in its early stage, is the incitement to flower-bud formation. Broadly speaking, this may be taken for granted whether the buds be crown, second crown, or terminals, as an instalment of growth is made between the buds mentioned; the degree of ripeness of the last instalment of growth being a matter of feeding combined with the nature of the season during the time the latter instalment of growth is being

formed. It is well known to growers that the second crown buds and the terminals open more freely and form more perfect flowers than do the first crown, yet the wood forming the last instalment of growth in this case is cruder and softer than in the other case.

Although we state that ripeness of growth is a necessary condition in the production of high-class flowers, we have also to consider that in the ordinary acceptance of the term the Chrysanthemum in habit is an herbaceous plant, flowering on the current year's growth; but unlike most other herbaceous plants, which usually bloom, in accordance with a fixed principle, at the point terminating the current season's growth, the Chrysanthemum has inherited or adopted a more erratic principle of forming incipient flower buds, terminating several instalments of growth instead of only one, as in the case of the herbaceous Phlox. Whether the incipient flower buds of the Chrysanthemum develop into flowers or give place to another wood developing into growth, is dependent upon the condition of the plant at the time, or of the requirement of the cultivator.

The action of wood and root growth are reciprocally dependent each on the other, but as the wood and leaves also ripen as the season advances, the extension of top growth is checked with the inevitable check to root action following, and this is the critical stage from which the over-ripe condition of the plant begins producing the inferior flowers due to this condition of the plant, brought about by too early bud formation.

Reverting to the second crown and terminal buds, their freer development and better quality may be traced to the later growth and the resultant vigorous root action when most required in the development of the flower and best suiting the exhibitor's requirements. In this case, although the growth immediately below the bud is not ripened, we may conclude the necessary food supply in the development of the flower is drawn on from below, where the products of elaboration have been stored by in the earlier part of the season.—A YORKSHIRE GROWER.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 12TH.

SCIENTIFIC COMMITTEE.—Present: Dr. M. T. Masters (in the chair); Mr. Veitch, Rev. W. Wilks, Dr. Russell, and the Rev. G. Henslow, Hon. Sec.

Acorn Cups Malformed.—Mr. French of Felstead sent specimens of this not uncommon phenomenon. It appears to be due to an arrest of the flower, probably by some insect attack, when the scales of the cup become enlarged and free.

Melons with New Disease.—Specimens were received from Mr. J. Fraser Smith of the Gardens, Cullen House, N.B., who writes as follows:—"The disease attacked my crop last year, and has again this, in both a sudden and deadly manner. An entire crop of twenty plants has perished in a few days. The disease first shows a spot on the leaf, then a part of the stem gets affected, and in two or three days the whole plant collapses. It is only at a certain time of the year, for the first crop in both years, which was grown in the same house, finished without any signs of it—*i.e.*, about the early part of August; while the second crop, about half-grown on the opposite side of the path, has all gone, as also a later batch planted on the same side as the first ones. Out of thirteen plants ten went off in one day. Two young Cucumber plants have also died in the same way, after they were 4 feet high.' The following report has been received from Kew:—"The Melon disease is caused by Scolecotrichum melophthorum, *Prill.*, a parasitic fungus. The disease is common in France, but I am not aware of its having previously been observed in Britain. Burn all diseased plants, as if they be allowed to rot on the ground a recurrence of the disease would be almost certain next season. Under any circumstances it would be advisable not to use the same ground for Melon-growing for at least two years, as the fungus spores are probably abundant in the soil."

Parrot Tulips Seeding.—Mr. Wilks brought ripe pods and seeds of this variety, which he had crossed with the pollen from other kinds of Tulips growing in his garden. It had been stated by growers that the Parrot Tulip had not been known to bear seed at all, and Mr. Henslow observed that of some bulbs received from Mr. Barr, in every case the pistil was abortive. It is proposed to raise plants from the seed thus obtained.

Abies bracteata Cones.—Fine specimens were received from Mr. A. Harding, The Gardens, Orton Longueville, Peterboro'. It is believed to be the first occasion of its fruiting in this country. They were borne by one of the finest specimens of this species in England. The tree is a native of South California, growing at one place only, in Santa Lucia, and is in danger of becoming extinct. The cones are remarkable for their long linear bracts.

Cedrela tooma? Fasciated.—A remarkable specimen, consisting of a spirally-coiled, flattened branch, two of the coils being welded together, was exhibited by Dr. Masters. The tree is a native of Santa Barbara of South California.

Abies balsamea, Tuber.—A specimen was received from Mr. Noble of a young plant which had developed a globular tuber-like excrescence below the soil. Similar cases had occurred some years ago in the same grounds, but the cause is not traceable at the present state of growth, though it might possibly be due to some injury by insects at a very early stage.

Juniper Berries, Gymnospermous.—Dr. Masters exhibited some berries of the common Juniper, received from Dr. Schröter of Zurich, remarkable for the three coherent bracts not having become fleshy enough to close in upon the seeds, so that the latter remained visible, free, and strictly "gymnospermous," as in the previous condition of the ovules.

Trapa natans, Fruit.—He also showed specimens of the Water Chestnut from a particular Italian lake having four knobs upon them, which do not occur on the ordinary form of this fruit.

Spruce Fir-cone, var.—He also showed cones having smooth-rounded scales, instead of the usual form. Dr. Schröter, who obtained it from Switzerland, referred it to Abies medioxyma; but Dr. Masters observed that this species is a dwarf Alpine or Arctic species, and regarded the specimen as a variety only of the Spruce.

Anthurium Spathe, Monstrous.—Col. Beddome sent a specimen having three spathes and the spadix commencing to branch, exhibiting a semi-proliferous condition.

Plants Exhibited.—M. Lemoine sent a spray of Tamarix Kashgarica, interesting as being a late-flowering species, from Central Asia; Panax sessiliflorum, with large, dense bunches of black berries, probably from Japan; the Begonia, odorant, having a delicate but very evanescent odour of lemon, and double and semi-double sports of B. semperflorens.

Galls on Roots of Oak.—Mr. Wilks brought remarkable galls, forming a large mass on the roots of Oak or Chestnut. They are also found on the roots of the Deodar. The galls are polygonal and wedge-like, so forming together a globular cluster about the root. They are produced by Cynips aptera (see *Gardeners' Chronicle*, 1841, p. 732, and 1874).

GRAPES AT TEWKESBURY LODGE.

FOR several years past Tewkesbury Lodge, Forest Hill, the residence of C. Bayer, Esq., has acquired more than local fame for the excellence of its Grapes. Having often seen them in good competitions, I took a recent opportunity when in the neighbourhood of inspecting them under natural conditions, and these are what many a gardener might envy. Structures of the very best construction, perfectly heated, borders well made, and, what is more, the crop and Vines were in the best possible condition, providing amply for home and exhibition purposes.

The vinery, which is span-roofed, measures some 75 feet in length by 24 feet in width, divided by a partition in its centre; one division being planted with a mixed collection consisting of Black Hamburgh, Buckland Sweetwater, Madresfield Court, Lady Downe's, Gros Maroc, Alicante, Gros Colman, Foster's Seedling, and Gros Guillaume. The Muscat house is not strictly devoted to the Alexandrian variety, but shares one side of the house with Mrs. Pince, Alnwick Seedling, Trebbiano, Mrs. Pearson, and Golden Champion. The only Vine that fails to give entire satisfaction is Mrs. Pince.

As showing the vigorous condition of the Vines, a young rod taken through the partition in the spring, and this carrying a heavy bunch at its base, has covered the whole length of the trellis, and apparently in a perfectly ripe state throughout. Being a cooler compartment it is hoped the desired colour may be obtained on the young rod. Spanning the path at each end are strong wire trellises, which are well furnished with useful bunches of Gros Maroc, constituting quite an object lesson in perfect culture, strict utility, and an ornamental aspect in the house.

The borders are confined inside, and are 2 feet 6 inches in depth, the turf for which was obtained from a meadow closely adjoining. The houses were planted nearly seven years since by the gardener then in charge, and are now under the care of Mr. W. Taylor. Other handsome structures have been erected, and still more are in contemplation for extended fruit growing, including Peaches, Nectarines, Plums, Pears, Figs, and Apricots. One house planted with Peaches and Nectarines on cross-trellises have made a wonderful growth, and there are healthy pot trees standing outside, sufficient to furnish another large house erected for that popular phase in fruit culture.

Beside the houses under notice there is an old range, which includes the vinery that did duty for some years previous to the erection of the handsome new ones. This is a lofty structure, 35 feet in length, and contains Madresfield Court, Duke of Buccleuch, Alnwick Seedling, Gros Colman, Black Hamburgh, Foster's Seedling, and Muscat of Alexandria. In this case the border is outside, but Mr. Taylor takes the precaution to protect it from the heavy autumn and winter storms by fixing pit-lights over to keep it dry and warm.

In a small lean-to house 12 feet in length, 8 feet in width, height at back 10 feet, front 5 feet, facing south, without fire heat, are Black Hamburghs. Three Vines were planted in 1891 in a small border inside. For the past five years well-finished Grapes have been cut from this small house, which has been quite a feature here. This year forty-three bunches have been taken, the heaviest weighing 1¾ lb. No provision was made for bottom ventilation, and the top ventilators have not been closed since the Vines were in flower. [Mr. Taylor has sent us a specimen bunch of the fruit from one of these Vines. It is a model in shape, and the berries fine in colour and size.]

The quality of the Grapes is so good in the newer vineries that it seems almost superfluous to particularise, but Madresfield Court and Gros Colman may be specially mentioned as doing remarkably well. Records gained during the present season support this view in respect to the first named; time and opportunity will prove what are the condition of the "Colmans." It may be interesting to note that during the past three seasons Mr. Taylor has won twenty-five first prizes, fifteen seconds, and eight thirds, in addition to three silver and one silver-gilt medals, and a cultural commendation from the R.H.S. for Grape Madresfield Court. Mr. Bayer has a very keen interest in fruit growing, and his gardener spares no pains to produce the very best in season.—W. S.

DECORATIVE WORK.

(*Concluded from page* 343.)

One feels somewhat diffident, although recognising the importance, table decoration bears in relation to a gardener's work, in approaching this part of our subject, by reason of the excellent practical articles so frequently to the front concerning it, but some margin may remain for the inclusion of a few hints. Circumstances alter cases, and tastes which have to be catered for vary considerably ; yet, generally considered, there are a few simple ethics which, in practice, seldom disappoint, and may, on the contrary, charm those who have suffered from an *embarras des riches*, resulting from heavy and laboured designs. Simplicity, lightness, gracefulness are within easy reach of all, yet not all are able to disassociate the rich and rare in the way of flowers, foliage, or plants from their object, hence ideas are apt to trend in the one direction.

For instance, at a flower show where some half dozen tables competed for the honours in this particular class, the first prize was justly awarded to a competitor who came last into the field on the eventful day, and certainly had the least material to work with. The judges, I know, had a bad quarter of an hour, for their decision was "bad"– at least, such was the verdict arrived at by the third prizeman, who himself point-judged his display in order to gain some salve for wounded pride from his fellow sufferers. "Third prize, indeed, for a grand lot of Orchids against a lot of wild rubbish put up by Miss ——; and three hours' hard work against her thirty minutes' sticking up without any trouble." However, the general public endorsed the judicial view, and that which the most are pleased with may be generally accepted as the most pleasing.

The secret of success with the prizewinner appeared to rest in a liberal addition of nodding Grasses in bloom springing naturally from a loose and light arrangement of Ox-eye Daisies, which, cut with long stems, were inserted in a central bowl of wet sand, small trumpet vases filled with similar flowers and Grasses being placed at intervals on the table. A great deal of time is often needlessly expended in strained and laborious effort, as was the case with our third prizeman, and this over-anxiety not only misses its mark, but virtually perverts the marksman's vision. Time and labour, and even choice material, count not in these cases, they are often, in fact, detrimental to the chief object.

When a gardener is pushed to extremities by reason of scarcity of material, or of time, he often makes a hit in the right direction. In carrying out a series of table decorations extending over a certain period of entertaining, the desire is a laudable one to afford as much variety as possible by distinctly contrasting arrangements of form and colour on successive nights. To this end many of our wildlings in their season lend themselves admirably. Having seen some of the happiest effects produced at a pinch by such means, one would impress upon beginners at the work, who are apt to look upon common things with contempt, the general benefit to be obtained by taking a broader view of the subject. Gardeners are, of course, initiated into this work at their embryo stage, and not a few seem chained down to copying the examples of early days. From one place in particular where table decorations were of the heavy and formidable type, young men went forth to carry the same doctrines into practice in their own particular sphere of work; so much was this the case that a gentleman who moved much in society said he "could trace the effect of the Blank Hall system wherever one of the pupils had been planted out."

During this season of the year, when high-coloured foliage abounds, seasonable displays of such can vie with the flowers that have fled, and, what is, perhaps, less understood, pleasing and distinct variety can also be given. It is as well in all cases that our decorator should note the effect of his work under artificial light, by a critical survey at the last moment, when he should, to obtain the best idea of it from the eye level, temporarily seat himself in various positions. Plant groups in this phase of decorating are peculiarly liable to the error of overcrowding. Gardeners are prone to lament the time now absorbed in this kind of decorative work, and not without reason; but where the matter is left to their own discretion they are, I think, often to blame, good as the motive may be. Such instances have, at least, come under notice, and not only been noticed, but privately remarked by their employers, who out of consideration for their feelings are loth to carry the matter farther.

Many ideas spring from what one has seen during a long experience of our subject. Now and again one notes where a happy, though probably accidental, break has been made in ordinary routine, and I often think that if our decorative hands were a little more daring much might be done in many ways, a few of which I have ventured to suggest. One of the most imposing displays I have ever seen in connection with the closing part of our theme was at the obsequies of a high dignitary of the Church. White flowers were at a premium, so heavy had been the tax imposed upon gardens in the neighbourhood, and when at the last moment a lady begged for something as a token whereby to express her respect it was not without some misgiving that a handful of Bougainvillea sprays was suggested. However, they were accepted, and simply twisted into wreath form without any addition to their flowers or foliage. As the funeral car slowly wound its way along the distance of a country road heaped with a mass of floral emblems, this bit of unique colouring was one of those happy hits I have endeavoured to describe. In decorative work our young gardeners have a field open to them, which is as practically unlimited as the subject is inexhaustive.—Decora.

BOTHY CUSTOMS—ON DUTY.

Relative to "A Young Gardener's" inquiry about the rules or customs governing the leisure hour in bothy life, the matter, as stated, whilst being one which directly concerns himself, is not without its indirect bearing upon the lives and duties of young gardeners generally. Moreover, the question is broad enough to include head gardeners, for in the body corporate of gardening "head" and "hands" must act in harmony for the good of the whole. Were it the case that clearly defined rules not only existed, but were generally accepted, that would close the question, or limit it to those exceptional instances for the guidance of which an established precedent could be quoted. In one sense, the broadest, this is not so; we may regard each and every garden as a little kingdom in its own way, affected, no doubt, to some extent, by certain cosmopolitan customs, but not sufficiently so to infringe upon that autonomy which is, and likely to be for long enough, the best for the purpose.

If it is possible to find two things exactly similar, or two cases strictly parallel (a philosophic question which has been philosophically negatived), it is not in gardens, in gardening, or in gardeners such are to be looked for. I would ask "A Young Gardener" to extract a moral from the above, which doubtless his good intelligence will have no difficulty in doing.

It is a habit of the writer to impress at every favourable opportunity the value of adaptability to circumstances in those cases where circumstances are beyond control. Some time since I casually came across a little book for business men entitled, "Tact, Push, and Perseverance." The two latter virtues seem to be inseparably bound one with the other, but not so the former. One sees now and again examples of the clever gardener, in which tact is conspicuous by its absence, and reading between the lines of "A Young Gardener's" letter, it may, I think, be from the want of a little tact that occasion has arisen for his questions, which shall be answered as far as ignorance of the place and parties immediately concerned will allow.

Question No. 1 is, "May I ask a gardener . . . if it is the rule to consider bothymen to be always under control?" This is the crux of this question. Yes! As a head gardener I liked my lads to feel and to know that during working hours I was their master, and afterwards, in the leisure hours, that I was their friend. As a master there was no questioning my authority, and as a friend, by entering into their recreations, their studies, and sympathetically aiding them in their ambition to be men, they were, most of them, I am proud to say, "always under control." My meaning is, I think, plain. "A Young Gardener" was "startled" as he was going home, being "off duty," by being told that "he had no right to go," that he "was in a bothy, and while there was supposed to be always in the place when he was wanted."

Passing over that most commendable desire to "go home," I do not attach much importance to this apparently despotic supposition of his chief, for, doubtless, there was some underlying reason for this arbitrary rule, supposing that it is the rule of that particular place, which I very much doubt. Head gardeners are not infallible, and the under one may have been too frequently running home, which betrayed the former into a hasty interdiction. The young clerk who asked permission for the third time within a few months to attend his grandmother's funeral was accorded it with the injunction that it was to be the last time of asking. The moral is clear; and, I think, the more our boys are made to feel that the bothy is like a home the less desire they will have to run from it at every opportune, or inopportune time.

Question No. 2: "If this were the rule of the place, why was I not told of it when I came?" With what has been advanced there is nothing to add beyond that what a gardener owes to himself and to his men is to have a clear understanding at the engagement to prevent any misconception and subsequent friction.

Question No. 3 concludes "A Young Gardener's" letter. It is, in fact, a satirical supplement to question No. 2, where the troubled one inquires, "Is it my luck to be under a kind, generous head gardener?" I hope so, young friend; and perhaps you will find, as I have found, that a rough manner often covers a kindly heart. Do not be faint-hearted. One master I served under for two years was of the crusty kind, and I knew not until the morning I was leaving that so well concealed under a cold reserve was a warm and sympathetic interest in my welfare; and what a pleasant surprise it was to me!

As previously stated, I do not attach much importance to

"A Young Gardener's" troubles, that is in viewing them from my period of life. They may be very real to him, but the time will come when, in looking back, he will smile upon them—that is if he meet them now in a right spirit. If he will turn back to "An Old Boy's" reminiscences of bothy life he will there note where the "off duty" men were sent to unload slack at a railway station on a Christmas Day, and other difficulties (?) of young gardeners' lives in those days. The young fellow who has to meet them, and who finds in each difficulty his opportunity, is the one who succeeds, and we know that among gardeners there are not a few failures. Few of us have what we like; most of us can, if we choose, learn to like what we have.

Men there are, I know, "dressed in a little brief authority," who are unapproachable to their subordinates, but they are not, happily, very common amongst our class. If "A Young Gardener" feels some little restriction upon him when "off duty," let him remember that "stone walls do not a prison make;" and respecting these little misunderstandings, which may arise in the best regulated gardens, both "head" and "hands" may sometimes, to their mutual advantage, find that "it is best for a servant to be sometimes deaf, and for a master to be sometimes blind."—WELL-WISHER.

CROCUSES.

THE pretty and modest Crocus is a favourite spring flower, useful for boxes and pots, but quite indispensable for beds and borders. Most soils and positions suit it, and it graces any spot where it is planted to an extent excelled by few other spring flowers. To attempt to describe a flower so well known as the Crocus would be superfluous; everybody has seen it at some time or other in gardens and in pots. It may be useful, however, to refer to the many modes of decoration for which it may be employed, and to describe the circumstances under which it thrives best. We may begin by noting that it is for outdoor planting that Crocuses are most largely employed. They make pretty masses in beds by themselves if the colours are judicously blended, and clumps of half a dozen roots planted together here and there form attractive bunches of flowers in spring. The earliness of the Crocus is one of its chief recommendations. It is in full beauty when the spikes of the Hyacinths are only half furnished with expanded bells, and the broad, richly coloured petals of the Tulips are still pressing closely to each other, as though loth to expose themselves to the nipping air. But fortunately they last a considerable time in flower, and are thus serviceable for edgings and bands to beds of the last-named flowers when they have at length fully developed themselves. For this purpose Crocuses are used to a considerable extent, and they are never seen to better advantage than when surrounding with a ring of purple or gold a mass of the more imposing Hyacinths; and after the Crocus flowers fade the leaves form an elegant green fringe.

A double row of white, blue, or yellow Crocuses, or a row of each makes a charming edging to a circular bed or long border, whatever it may be planted with; and to any corner that would otherwise be bare they would impart warmth and cheerfulness. There is not much diversity in their colours; shades of purple or blue, yellow and white being all that are represented, but many of the varieties are prettily flaked and striped. A mode of planting these flowers not commonly employed is practised in the London parks. The corms are dotted about here and there amongst the grass in irregular order, purple, white, and yellow being intermixed, and when they push their flowers through the turf early in the year the effect they produce is well worth copying. This plan might be followed on any grass plot. The present is a good time for planting, squares of turf being cut out, the soil beneath well stirred so that water can pass away freely, the bulbs placed in, and the turf placed in position again. In very poor or heavy ground it is desirable to remove some of it and add fresh for insuring the growth and increase of the corms, but in many lawns that is not necessary, provided the soil is stirred and sand added if it is of a heavy nature. Some persons simply make holes in the grass with a pointed stick, press in the bulbs and tread the grass over them, but that is not a good plan, as they are then practically suspended in the pointed cavities, and these in firm wet ground act as so many miniature water-traps, preventing the growth and causing the decay of the corms. Lawns in which bulbs are planted should not be mown in the spring until the leaves of the bulbous plants are matured and commencing to decay.

Than Crocuses few more suitable flowers could be chosen for the decoration of graves, over which, with the drooping, pure white Snowdrop flowers, they will bloom with a quiet beauty well in keeping with the associations of the spot. We have more than once been asked to give advice on the planting of graves, and may say that Crocuses and Snowdrops should be planted now for their decoration in spring.

For pots and boxes Crocuses may also be used with advantage. In the former they may be planted in mixture, or one sort only may be planted in each pot. The light variety with flat petals shown in the front is a very early yellow sort named Cloth of Gold; the others are the ordinary purple, white, yellow, and striped varieties, which are better. Five corms may be placed in a 5-inch pot, which is a convenient size for growing them in. They may be placed under ashes or fibre for a time as advised for Hyacinths and Tulips, and be subsequently removed, watered as they require it, and placed in the greenhouse or on a window-ledge to bloom. They are useful in boxes if associated with Hyacinths and Tulips: they should be in the front unless Snowdrops are employed, in which case they may form a second row.

Crocuses will thrive in any soil that will grow other bulbs well, and the mixture that has been recommended for Hyacinths will produce extra large flowers. But no trouble need be taken to prepare a special compost, as any ordinary garden soil, mixed with sand, will suit them. They may be covered with about 2 inches of soil. When planting in lines the quickest way is to draw a drill with a spade, press in the Crocuses, and turn the soil over them. They may be planted and potted now, and the earlier this is done the better will be the growth and the finer the flowers.—A.

NOTES FROM DUBLIN.

A PEEP into "The People's Gardens" lately revealed more brightness than one could have expected to find with the advent of October. It was a casual call, but compared very favourably with a special visit made some time previously, when summer sun had been conspicuous by its absence and results were disappointing. Not so, however, this late autumn day when, expecting to find little remaining of the ephemeral gaiety of summer bedding, it was comforting to find such warm tones of colour given off by Begonias and 'Geraniums," as well as grateful to have odours galore, of the good kind, a number of standard bushy-headed Heliotropes laden with flowers and fragrance being responsible for most of the latter delights.

Entering from the city side, where a gentleman with many bright buttons and much gold lace personifies law and order, and enforces it by a vigilant look-out for stray dogs (by-the-by, our last visit witnessed a frolic through the flower beds of two noble specimens of the Irish red setter in defiance of all conventionalities), a walk through a shrubbery brings one to the *pièce de resistance* in the way of bedding. This is, I suppose, similar to what obtains in most public gardens, hence calls for little comment. One could not fail to notice that charming old friend, Calceolaria amplexicaulis, the most pleasing feature in a substantial ribbon border. In this part of the gardens seats are abundantly disposed in every available nook; not much in use to-day, but sufficiently occupied to typify all sorts and conditions of our Dublin folk; the well-to-do, and the not-well-to-do, with the ne'er-do-well, are all in evidence. We watch them all, as well as the flowers; notably a lady with a covetous-looking handbag, a student of botany, mayhap, by the great interest displayed in one of the gardeners who is dismantling a bed of choice succulents. However, to his credit be it said, no specimens are transferred; she goes empty away, and we wander away down by the lake.

Here, at the lake, one enjoys the good taste displayed by the planter. On the opposing bank a bold planting of Tritomas is the right thing in the right place, and some noble foliaged plants naturally disposed in the vicinity of the water scene give the happiest effect. A group of Bullrushes, common as the plant is, suits the margin admirably: one might, in fact, imagine the whole thing to be a piece of Nature's handiwork were it not that, what is doubtless an oversight, the large earthenware supply pipe protrudes rather prosaicly from the bank. We would like to wade out and adorn its mouth with a few rocks; but some stern official eye might be focussed our way, and trouble would ensue. Here, in a secluded nook, is a fine bit of the rockwork builder's art: or is it natural rock, strata upon strata being so cleverly superimposed? An overflow pool is surrounded and centred by handsome foliage. Broad-leaved Aralias, noble Cordylines, and a vigorous growth of Osmunda regalis occupy this sheltered place, which is variously approached from the plateau of the flower grounds by flights of informal steps.

On the bold rockeries above, near the opposite boundary to the city side, things have grown almost too luxuriantly, and notably so on the rock-studded bank which backs up the ribbon border previously noticed. Yet in this particular place the dense overlapping growths of Ivy could not but be admired, being quite a feature in its way. Having returned to this part of the grounds, the new circular fenced-in rosery must not be overlooked. Some two years since we saw it being formed, and all the Roses, including the Teas at the pillars and chains, have grown apace, and look remarkably clean and healthy. The entrance gate to this sanctum is padlocked, and rightly, too; but as the backs of the labels only are visible to interested ones, we would like to climb the fence and face them outwards, that all who run (outside) might read. Near at hand, half a dozen good specimen semi-hardy Palms, spaced out by the side of a walk, are cushioned in Sedum spectabile, now in all the glory of its autumnal bloom. Nothing could be finer as an autumn plant than this Sedum boldly planted on the grass.

Back again to a far corner, in a kind of sub-tropical nook formed by a dense background of evergreens, the most critical of critics could not but derive unqualified pleasure, and one fairly revels among groups of graceful Bamboos and grand specimen Eulalias in variety. Not far away, in a large bed, from a groundwork of smaller things, spring a number of the noble Musa ensete, as yet unscathed by wind or weather. There is no doubt but that much of the beauty and interest pertaining to these charming gardens is to be found in the great number of evergreen shrubs employed in the original planting. Among these luxuriant Hollies in plentiful variety are a feature. The treatment of this planting has also contributed not a little to the good effect, deep bays being formed, and these in turn being utilised for the cultivation of flowering plants. One such was noticed of Lilium lancifolium, which, although now past its best, must up till lately have been very fine.—K.

Notes & Gleanings

EVENTS OF THE WEEK.—So far as we are aware the only event in London during the forthcoming week that will be of particular interest to horticulturists is the meeting of the Royal Horticultural Society. This will, as usual, be held in the Drill Hall on Tuesday, the 26th inst. Considering the weather that we have been experiencing, the display ought to prove a good and an interesting one.

—— WEATHER IN LONDON.—The weather in London since our last issue went to the machines has been characterised mainly by its mildness. On the evening of Friday last it rained rather heavily. Sunday and Monday were exceptionally mild. On the evening of the latter day rain fell, and continued over a large part of Tuesday. Wednesday morning was foggy.

—— WEATHER IN THE NORTH.—The autumn so far has brought more than the average of rain, and considerable difficulty has occurred in securing the grain crops. The thermometer has frequently fallen to the freezing point, and hoar frosts have already been frequent. Snow has fallen over and again on Ben Nevis. On the morning of the 13th 2° of frost, and 8° on Thursday, practically brought the season of outdoor flowers to an end. Since then a great deal of rain has fallen. Tuesday morning was fine, with temperature 54°.—B. D., *S. Perthshire.*

—— ROYAL HORTICULTURAL SOCIETY.—We are requested to announce that the dates fixed for next year's meetings are as follows :—1898 : January 11th, February 8th, March 8th and 22nd, April 12th and 26th, May 10th ; Temple Show, May 25th, 26th, and 27th ; June 14th and 28th, July 12th and 26th, August 9th and 23rd, September 6th and 20th ; Fruit Show, Crystal Palace, September 29th, 30th, and October 1st; October 11th and 25th, November 8th and 22nd, December 13th. Any gentleman willing to deliver a lecture on any of these dates would greatly oblige by communicating *at once* with the Secretary, 117, Victoria Street, S.W.

—— HORTICULTURAL CLUB.—The first dinner and conversazione for the session 1897 and 1898 took place on Tuesday evening last, and there was a good attendance of members. Mr. Harry J. Veitch occupied the chair, and there were present Rev. W. Wilks, Rev. H. Pemberton, Rev. H. H. D'Ombrain, Messrs. Williams, Cockett, C. Pearson, T. Francis Rivers, H. Turner, Gurney Randall, Assbee, Gordon, Geo. Monro, M. Garcia, and Herr Hugo Muller, President of the Pomological Society of Vienna, who was the guest of the Club for the evening; his health was proposed by the Chairman. A paper was read by Mr. T. Francis Rivers on "Orchard Houses and Fruit ;" an interesting discussion followed, and a cordial vote of thanks was awarded to Mr. Rivers for his excellent paper ; this we hope to give in some future issue.

—— AUTUMN LEAF TINTS.—These this season are truly superb. Rarely have they been seen more beautiful. Leafage in every direction, instead of being withered up, is dying off in rich golden or brown tints, so that fleeting as this autumn colouration will be, how much does it compensate us for the long leafless winter season which so many seem to deplore, yet does help us the more fully to appreciate both autumn tints and spring's varied and lovely greens. But there is an inference to be drawn from this high leaf colouration that cannot be ignored. It means that wood and buds have in all directions ripened or matured with almost unusual excellence, and for that reason we are entitled to look with more than ordinary hope for a fruitful season and luxuriant produce on all fruit bearers, whether wild or cultivated. Whilst we had early rains of exceeding value, helping materially to promote root action and wood formation, we have later had a glorious ripening time; indeed, so far almost a perfect autumn. There have been none of those rain floods which marked the autumn of last year, and did so much to demoralise growth and buds. We saw too plainly this summer the results of that demoralisation in the great decrease of crop compared with the excess of bloom. Next spring, there having been no such injurious factor in the case, as the high-coloured foliage now shows, there should be bloom of the most perfect character, and when we have it amply supplied with healthy pollen, rarely, indeed, do a few white frosts produce material injury. Most certainly the present leaf colouration justifies high anticipations of a good fruit crop next year.—A. D.

—— THE QUEEN AND THE ROYAL HORTICULTURAL SOCIETY.—We learn with much pleasure that her Majesty has been graciously pleased to confer the Diamond Jubilee Medal upon Sir Trevor Lawrence, Bart., President of the Royal Horticultural Society, her Majesty being herself patron of the Society.

—— AWARDS AT THE VICTORIAN ERA EXHIBITION.—We are informed that the Jury of the Victorian Era Exhibition at Earl's Court has awarded to Messrs. J. Laing & Sons a diploma and a gold medal in recognition of the manner in which they have planted the numerous beds in the gardens with flowering plants and shrubs.

—— THE LONDON COUNTY COUNCIL AND EDUCATION.—At the meeting of the London County Council on Tuesday the following resolution was adopted :—"That it be referred to the Parks and Open Spaces Committee and to the Technical Education Board to consider and report upon the practicability of laying out plots of ground in certain parks in such manner as will afford assistance to scholars of elementary and secondary schools in the study of practical botany."

—— GARDENING APPOINTMENTS.—Mr. Hugh A. Pettigrew, for some time foreman in the kitchen and fruit gardens, Cardiff Castle, has been appointed gardener to the Right Honourable Lord Windsor, St. Fagan's Castle, Glamorganshire. Mr. George Parrant, for six years general foreman at Ashby St. Ledger's Lodge, Rugby, has been appointed head gardener to A. E. Guest, Esq., The Cedars, Bere Regis, Wareham, Dorset. Mr. Herbert Hall, until recently head gardener at Broadwater, Godalming, as head gardener to R. H. Otter, Esq., Queenwood, Chertsey.

—— PREVENTION OF THE ONION MAGGOT.—I notice your correspondent, W. Rushton (page 370), highly recommends hellebore powder for the prevention of the Onion maggot. The following is a simple preventive given me by an old market gardener in Cumberland some years ago, and since I have used it I have never been troubled by either the Onion or Parsley fly. This simple receipt is to mix Parsley seed amongst the Onion seed when sowing. The old gardener said the Onion fly did not relish the smell of Parsley, nor the Parsley fly the smell of Onions. Whether this is correct or not I cannot say ; but since trying it I have grown splendid crops of both Onions and Parsley on ground where before it seemed an impossibility to grow either.—J. C., *Lancashire.*

—— HILL AND VALLEY TEMPERATURES.—The difference of temperature between stations in a valley and upon a hill is one of considerable importance to agriculturists, and has occasionally engaged the attention of observers both in this country and abroad. The Agricultural School at Scandicci, near Florence, has made comparative observations during the whole of the year 1895 at two stations, one being situated in a plain, and the other about 220 feet higher, on the side of a hill, both having a north aspect, and the thermometers sheltered from rain and terrestrial radiation. The detailed observations and generalisations are published in the "Bollettino Mensile" of the Italian Meteorological Society for August last. The results are very interesting, and show that in the plain the minimum temperature is generally lower, while the maximum is higher than that on the hill ; in other words, the plain is colder during the night and warmer during the day. The mean annual temperature in the plain was nearly 3° below that on the hill.—("Nature.")

—— A FAIR CROP OF APPLES.—While some are bewailing the lightness of their crop of Apples this season, others are rejoicing in a wonderful supply. One of the most remarkable crops I have seen for a long time I noticed a few weeks ago in an orchard connected with the gardens at Wellesbourne House, about seven miles from Warwick. The trees bearing such fine crops were not old stunted ones, but standards in their prime, having health and vigour as well as fruitfulness. Every branch was literally "roped" with fruit, almost as evenly placed as if they had been secured in position by artificial means. One would naturally expect to find the Apples somewhat small on trees carrying such tremendous crops. This, however, was not the case here, for Mr. Liney, the energetic and practical gardener, as soon as he found he had secured so good a "set" of Apples, proceeded to feed the trees in earnest. Liquid manure from stables and cesspools was poured freely around the trees, and as far away as the branches extended. Under this liberal treatment both trees and crops grew apace, till they presented, as at the time of my visit, an object lesson in successful fruit culture. The varieties were Blenheim Orange, Hoary Morning, Golden Spire, Bess Pool, Wealthy, and several others. One favourable point in connection with the situation of the trees is that they are sheltered on the north and east by a fringe of other trees. This is worth the attention of planters.—H. D.

—— ROYAL APPOINTMENT.—Messrs. Dobbie & Co., seed growers and florists to the Queen, have been honoured with the following addition to their Royal Warrant of Appointment:—"The name of Andrew Mitchell is added to this Warrant as one of the firm of Dobbie & Co. by desire of the Lord Steward, the Earl of Pembroke.—Signed, T. C. March, Secretary, Board of Green Cloth, Buckingham Palace, 16th October, 1897."

—— DISTRIBUTION OF VICTORIA MEDALS.—The next meeting of the Committees of the Royal Horticultural Society will be held on Tuesday, October 26th, at the Drill Hall for fruit, vegetables, flowers, and Orchids. At 1.30 punctually the President and Council entertain at luncheon the sixty recipients of the Victoria Medal of Honour, granted by her Majesty's gracious permission in celebration of the completion of the sixtieth year of her reign. The lecture announced for the 26th will be postponed, and instead thereof, at three o'clock, the sixty medals will be distributed to the recipients by the President in the Drill Hall.

—— HERBACEOUS PÆONIES.—Beautiful as these are in the summer, grand indeed as are their flowers, what a penalty has to be paid in the autumn for this beauty, because the leafage dies off to a dirty brown hue so early, and must remain for some time apparently to mature the crowns ere it is safe to cut it away. Is it really needful that the stems should thus remain uncut so long after the leaves have become brown and unsightly? I have been told that early cutting, that is as soon as the leaves begin to decay, would materially weaken the crowns for the succeeding year's blooming. There are few herbaceous plants where such is the case, and of which the growths may be cut so soon as the leafage dies. The various German Irises are also very unsightly in the autumn as the flag-like leaves decay. Really these plants hardly seem worth places in the garden, especially when we get such wondrous beauty from the English and Spanish varieties.—A.

—— THE QUALIFICATIONS AND DUTIES OF A GARDENER.—Mr. J. Mayne, gardener to the Hon. Mark Rolle at Bicton, read the first paper in connection with the autumn session of the Devon and Exeter Gardeners' Association at the Guildhall, Exeter, on Wednesday last, taking for his subject "The Qualifications and Duties of a Gardener." He said that when a youth started to learn gardening he should begin in the kitchen garden. The majority of youths wanted to start under glass, but if they did they did not care to go back and work in the kitchen garden, and so knew next to nothing about the latter very important branch. He considered a youth ought to serve at least two years in the kitchen garden, and, if possible, be moved into the flower garden for another twelve or eighteen months, especially if the latter were away from the kitchen garden any distance, and where a regular staff of men was kept for each department. He would get an insight into bedding arrangements in early summer and again in the autumn, as well as the general routine practised in a well-kept garden, where neatness should always be noted. The youth's next move should be under glass, and his first duty there, for a few months, at any rate, should be to work with the foreman or a good journeyman to get an insight as to airing, shading, and watering. The last-named was of the utmost importance in gardening. He should spend one year at least in the plant and another year or more in the fruit department. Then, if a youth had done between three and four years outside, as advocated, he ought to make a change, and, if possible, get into another county, as the climatic conditions varied so much, and because of the necessity of making experience as wide as possible in that respect. Two years was quite sufficient for a young man to remain in one place after his first post. What he required was to gain fresh experience, because each gardener had his own *modus operandi*, and in after-life he would be able to use his own discretion as to which method or practice would be most successful. Probationers ought in all spare hours to endeavour to educate themselves by reading and studying, make a practice of keeping a diary, so as to be able to enter each day what work had been done under glass as well as outside, which they might, in the future, find of great service as a book of reference. Mr. Mayne proceeded to consider the fully qualified gardener and his duties. When a man took his first head place or new charge his permanent duty should be to find out what his employer's likes and dislikes were respecting fruit, flowers, and vegetables; next to secure discipline and punctuality. He must thoroughly understand pruning, disbudding, and thinning, and should perform such work, as well as the more delicate seed-sowing and the packing of fruit and flowers, as far as possible himself, and should closely superintend watering and outside work. He should also pay nightly visits to see that temperatures of houses were properly maintained. A vote of thanks to the essayist was passed.

—— DEATH OF Mr. I. DAVIES.—There died at Ormskirk, on the 10th inst., one of the old school of nurserymen, Mr. Isaac Davies, of the Brook Lane Nurseries, at the ripe old age of eighty-five. He was the raiser of many good Pelargoniums, Cinerarias, and Calceolarias nearly forty years ago. Azalea and Rhododendron hybrids, through his skill, have found their way into commerce. Azalea Daviesi, Avalanche, and Rhododendron præcox, the beautiful greenhouse varieties, Countess of Derby, Countess of Sefton, and Countess of Skelmersdale, are amongst the many the deceased gentleman put in commerce.—A. O.

—— CYCAS REVOLUTA IN FRUIT.—I send herewith for your notice a fruiting piece of Cycas revoluta. We have two large plants here, and this year one has thrown up a fruiting crown. Will some reader kindly say if it is a common occurrence, also if it will spoil the plant? I believe there are male and female plants, which, no doubt, through want of pollenising, accounts for the small ovules, of which there are several dozen, being hollow. There are only four or five large ovules (as per specimen); these contain a kernel. It is our intention to try if they will germinate. Any information respecting it will be greatly appreciated.—T. LEITH, *Beaurepaire Park, Basingstoke.*

—— "FAKED" POTS OF CHRYSANTHEMUMS.—A fraud that was common a year or two ago seems to have again made its appearance, that is, the "faking" of pots of Chrysanthemums, which are palmed on an unsuspecting public by peripatetic vendors. One day last week a gentleman in Kilburn bought half a dozen pots filled with vigorous looking plants, covered with beautiful blooms, at 1s. 6d. each. An hour or two later while examining his purchase, he had his suspicions excited by noticing a couple of varieties of white in one pot. He emptied it out and found that the spikes had been cut from plants, and firmly embedded in the soil in the pot. Not one of the lot had a root!

—— PRESENTATION AT EASTNOR CASTLE GARDENS. — Mr. F. Harris, who has been head gardener at Eastnor Gardens, has resigned his position, and on Saturday last, after he had entertained the garden staff and a few friends to supper, he was made the recipient of a gold watch and an illuminated address. Inside the case of the watch was the following inscription—"Presented to Frank Harris by those who have been connected with the Eastnor Gardens during the nine years he has lived there, as a token of esteem (October, 1897)." The address spoke in praiseworthy terms of the way Mr. Harris had carried out his duties, and wished him every success in the future. Mr. W. Coleman, agent to Lady H. Somerset, made the presentation. Mr. Harris thanked Mr. Coleman for his kind remarks.

A GARDENER'S HOLIDAY.

As the season comes round, even a gardener looks for a turn somewhere, and in that respect I am one of the fortunate ones, for my employers never fail to remind me to take my holiday.

I have long had a desire to see Aberdeen, so I made my way to Hull, placed my bag on a steamer, and then, having a few hours to spare, went to Beverley to see Mr. G. Swaile's Roses, and was shown a grand collection. The plants, which have not been fed to produce big show blooms, but short solid wood, are dwarf and sturdy, and I feel sure they will produce excellent flowers. I was also shown an interesting garden at Beverley belonging to Mr. Boyes, which is full of seedlings, hardy fruit trees, bees, and birds. I quite expect some of the seedling Apples will be heard of in high quarters in the future. But time and tide will not wait, so I returned to the boat, which arrived in Aberdeen after a twenty-two hours' run. Being Sunday afternoon, everything was very quiet. Sandy was wearing his religious face. However, I took a seven-miles drive up the Deeside, and found it both enjoyable and instructive. The next morning I made one of an English party who took return tickets to Braemar. The railway runs along the beautiful valley of the Dee as far as Balater, thence by coach, passing Balmoral and Old Mar Lodge on the way. I wish I could give readers an idea of this lovely piece of country. Balmoral is situated in the most beautiful valley imaginable. The Pine-covered hills are superb, and such splendid specimens of Araucaria imbricata show the climate must be very temperate there. A hearty lunch at Braemar, and our return journey commenced.

On Tuesday morning I found my way to Messrs. Cocker & Sons' Rose Nursery, and was being shown through the Rose portion when Mr. Cocker, jun., who was acting as guide, was called away to the death bed of his father. The nurseries are situated on a slope facing south, but as the builders are making sad havoc, laying out roads and streets through the middle of the Rose ground, the firm will have to seek for a fresh site very soon.

I was shown over the granite quarries and works, which were very interesting. Aberdeen is a beautifully clean city, and well worth a visit. Nothing could excel the trip back to Hull. The sea was as smooth as oil, the sky lit at night by innumerable stars, light night, and the day warmed by the brilliant sun. After spending a few days on the Lincolnshire coast I returned home to my duties.—J. MALLENDER.

ROSE CRIMSON RAMBLER.

AT the opening meeting of the Torquay Gardeners' Association, the President, Dr. R. H. Ramsay, in his annual address, gave an interesting instanee of an old Rose being reintrodueed with great sueeess as a new variety—namely, Turner's Crimson Rambler. He knew it, he said, forty years ago in the garden of Mr. Jenner of Edinburgh. I am inclined to think he was not correet. Can any reader kindly give me information about it?—C. D. ELLIOTT.

ROSE NOTES.

IT has oeeurred to me that a few notes upon such Roses as invariably give a good autumnal display may be welcome. This year those I will name are even better than usual. For that matter, all our Roses have been good later in the season than is generally the case, and at present (first week in October) our Rose gardens are almost as lovely as is often the case during July. The weather has been favourable; there have been welcome showers, a warm soil, fewer insects and diseases than usual, and, if we exeept a few rather boisterous winds, the late autumn of 1897 has been one of the best for Roses during the last decade.

Several of our best autumnal Roses are not only good at that date, but give us a pleasing show all through the Rose season. It is these we should plant mueh more freely than is the ease in many gardens, there being far too great a tendeney to plant sueh varieties as are seen in grand form at exhibitions. One scarcely ever sees Dr. Grill, G. Nabonnand, Rainbow, Camoens, and others of like form, at an exhibition, unless it be in some of the few garden elasses and displays at the National Rose Society's exhibitions. I would warn any intending purchaser of the absolute neeessity of looking up the habit of a Rose before planting it merely from the fact of seeing it so grand in the exhibitor's stand.

One of the best Roses now in bloom is G. Nabonnand. It is good all through the season, is matchless in colour and perfume, the foliage is particularly handsome, and it is a really grand grower. Camoens is also good; Dr. Grill, Bardou Job, Beauté Inconstante, Comtesse de Casserta, Crimson Bedder, G. Regis, Madame Pernet Dueher, Papa Gontier, Madame Isaac Pereire, William Allen Richardsou, Maman Coehet, Souvenir de la Malmaison, Marquis of Salisbury, Queen of Bedders, Auna Ollivier, Boule de Neige, Mrs. R. G. Sharman-Crawford, Mrs. Rumsey, Mrs. W. C. Whitney, Mrs. W. J. Grant, Caroline Testout, Dupuy Jamain, Marehioness of Lorne, Franeisea Kruger, Madame Hoste, Général Jacqueminot, Homère, La France, Rubens, Safrano, Madame Faleot, Madame Charles, Madame Lambard, Marie Van Houtte, Mrs. John Laing, Perle des Jardins, Souvenir d'un Ami, Marjorie, Edith Gifford, Kaiserin A. Victoria, Red Safrano, Viseountess Folkestone, and Lady Mary Fitzwilliam are others whieh never fail to give a good autumnal crop in my garden, and are also in good form during the earlier part of the season.—ROSARIAN.

ROSES FOR MARKET.

DURING the time Roses are not plentiful out of doors, and also when those in the average amateurs' houses are not in full eut, whieh ranges from about the end of March until the end of May, Roses generally command a paying price in the market. It is when plentiful, and when almost every little greenhouse ean produee a few blooms for the proprietor and friends, that Roses are at the ridiculous priees amateurs reeeive for their small consignments. Unfortunately for them, they imagine they will reeeive mueh the same prices as they were asked for a few blooms some month or six weeks earlier, not allowing for waste, and a small margin as profit to the retail florist; and more important still, forgetting, or not realising that only a couple of weeks bring a vast quantity of Roses in at one time.

During the months of April and May almost every Rose that is growu under glass is in full blossom, and the only really paying seasons are between Oetober and the end of Mareh; the nearer to Christmas and the early part of the year the better. They also rise in value very rapidly after the first smart frost, as up to that time we can eut from the open. Popular as the Chrysanthemum may be as an early winter flower, the public never really deserts the national flower, and Roses are always in demand. Of course, to get them at these desirable seasons we must take a rather different course to that made use of by the average amateur, henee these notes.

First of all I think it would be well to give a short seleetion of varieties, as no objeet is attained in having a large number. The best are the best, and it is only a matter of planting more of these. I have found Niphetos the best pure white; Princesse de Sagan and W. F. Bennett the best short-growing erimsons, and Général Jaequeminot the best red Hybrid Perpetual; Prinee Camille de Rohan and Fisher Holmes the best very dark varieties; Mrs. W. J. Grant, Mrs. W. C. Whitney, Papa Gontier, and Madame Lambard the best deep pinks or rosy erimsons; Souvenir d'un Ami, Catherine Mermet, and Mrs. R. G. Sharman-Crawford, pinks; Isabella Sprunt and Perle des Jardins, yellows; Madame Falcot and Franeisea Kruger, apricot and saffron; with Maréchal Niel, W. Allen Richardson, and Reine Marie Henriette as climbers; G. Nabonnand being a grand salmon pink.

If asked to select six from the above, always bearing in mind that they are wanted to force early and open their flowers well, I would keep to the three climbers, and add G. Nabonnand, Niphetos, and Madame Falcot. Perle des Jardins, Mrs. W. J. Grant, Catherine Mermet, and Général Jaequeminot come next in my estimation.

There are two methods of obtaining Roses between October and the end of March, some establishing the plants in borders, and others keeping the whole of them in pots. We find a combination of these methods the most servieeable, and it may be well to deseribe the house the Roses are grown in, as being the shortest way of dealing with the subjeet. The house runs north and south, thus receiving the morning and afternoon sun, while at midday the rafters afford a partial and welcome shade. It is 22 feet wide, 120 feet long, and 10 feet high. There are uprights through the eentre, and supports to a purline on each side, these supports resting upon the outside walls of the eentre border. The side walls are 3½ feet high, the side borders the same width, as is also the path going round the eentre border, which is 8 feet wide. When empty, the spaee allowed for pathway seems exeessive, but if you will follow me you will see how it is made use of.

The paths are sunk to a depth of 1 foot. This gives more head room without extra height in the structure, and also makes the borders more convenient. All around the eentre border a 9-inch wall is built, about 15 inehes in height, and the top of this is concreted over to make a level surface. The walls keeping up the side borders are one brick thick only; and outside of these, but in the pathway, runs a double row of 4-inch pipes; a single 4-ineh pipe runs along close to the outside walls, and about 6 inehes above the surface of the border. Shelves are fitted to the purline uprights, and come in very useful at many times of the year. There is no bottom or side ventilation, but some fair-sized lights at the top.

Now, a word about the soil in the borders. This consists of good turfy loam, some very stiff earth, and a large proportion of decayed weeds, vegetable refuse, and leaves, upon whieh a quantity of night soil was placed some few months previous to use. By burying this a little all unpleasant odours are lost; but for that matter, if one is to grow for market, the fastidious nose must be left behind, the foliage and flowers feeding upon ammonia from manures to a mueh greater extent than many persons would credit.

Against the side walls are plants of the medium growing varieties already named, these being trained to three wires, and planted about a foot from the wall. Upon each purline support a climber is growing, these running over the cross ties and along the purlines. Pruning must be dealt with in its own place. Each side, and also the eentre border, is used for Roses in pots, and when a row of healthy plants stands around the centre border, upon the 9-inch wall, their growth spreads out so mueh that 3½ feet is barely enough for the pathways, especially as there is overhanging growth from the side borders as well. The house is divided into two seetions, stop valves being fitted so that one section can be heated without influencing the other. So much, then, for the house and its arrangement; we will now go a little closer into cultural details.—PRACTICE.

(To be continued.)

THE ROYAL HORTICULTURAL SOCIETY.

EXHIBITORS' CARDS AT THE DRILL HALL.

I DO not know who is responsible for your report of the doings of the Fruit Committee at the Drill Hall on the 12th inst. I sent up a small collection of Apples with the intention of showing what could be done here amongst the coaldust and smoke, and I was very pleased to hear from the Secretary that I had been awarded a silver Banksian medal. The way in whieh you have alluded to them in the Journal is inaccurate, in fact, reads ridiculous to me. The report says, "J. Ester, Esq., Wakefield, showed a few Apples." I should be extremely obliged if, in your next issue, you would correct it to something like the following:—"J. Easter, gardener to Lord St. Oswald, Nostell Priory, Wakefield, was awarded a silver Banksian medal for a collection of Apples."—JOHN EASTER.

[Well may the award of "J. Ester, Esq.," appear "ridiculous" in the eyes of our correspondent, Lord St. Oswald's able gardener. The Royal Horticultural Soeiety is responsible for the error, which does not appear in our columns alone. Our reporter copied from the card which the officials of the Soeiety attached to the fruit. We do not know whether all exhibitors write their names and addresses fully and clearly or not when making their entries; but we do know that the inscriptions on the R.H.S. cards have many times been incomplete. Errors of a similar description to the one cited have been passed into the Press before, while others have been detected and corrected. It used to be the custom to have the names and addresses of owners of exhibited produce boldly and clearly written on the cards, also the name of the gardener in all such cases as Mr. Easter's. The entry of this exhibit ought to have been as from "Lord St. Oswald, Nostell Priory, Wakefield; gardener, Mr. J. Easter." This is in exact accordance with the instructions of the Royal Horticultural Society in par. 27, page 9, of the Society's "Rules for Judging," and if the injunction had been followed the error in question could not have occurred.]

ORCHIDS

Cypripedium hirsuto-Sallieri.

The collection of Orchids grown at Burford Lodge by Mr. W. H. White for Sir Trevor Lawrence, Bart., is rich in rare species of the greatest interest. As well as these, it comprises numbers of handsome hybrid Orchids of various kinds, and amongst the most beautiful of these must be classed Cypripedium hirsuto-Sallieri. This was shown at the Drill Hall in the spring of this year, and received from the Orchid Committee an award of merit. A flower is depicted in the woodcut (fig. 58). With such a name as this there is no necessity to give the parentage. The flower is of good size and of exceptionally good substance. The dorsal sepal is delicate greenish yellow, surrounded by a broad white band; while the pouch is of a similar hue, but is sparsely suffused with brown. The petals are soft rose at the lip and yellow at the base, so that it may readily be imagined how beautiful is this hybrid.

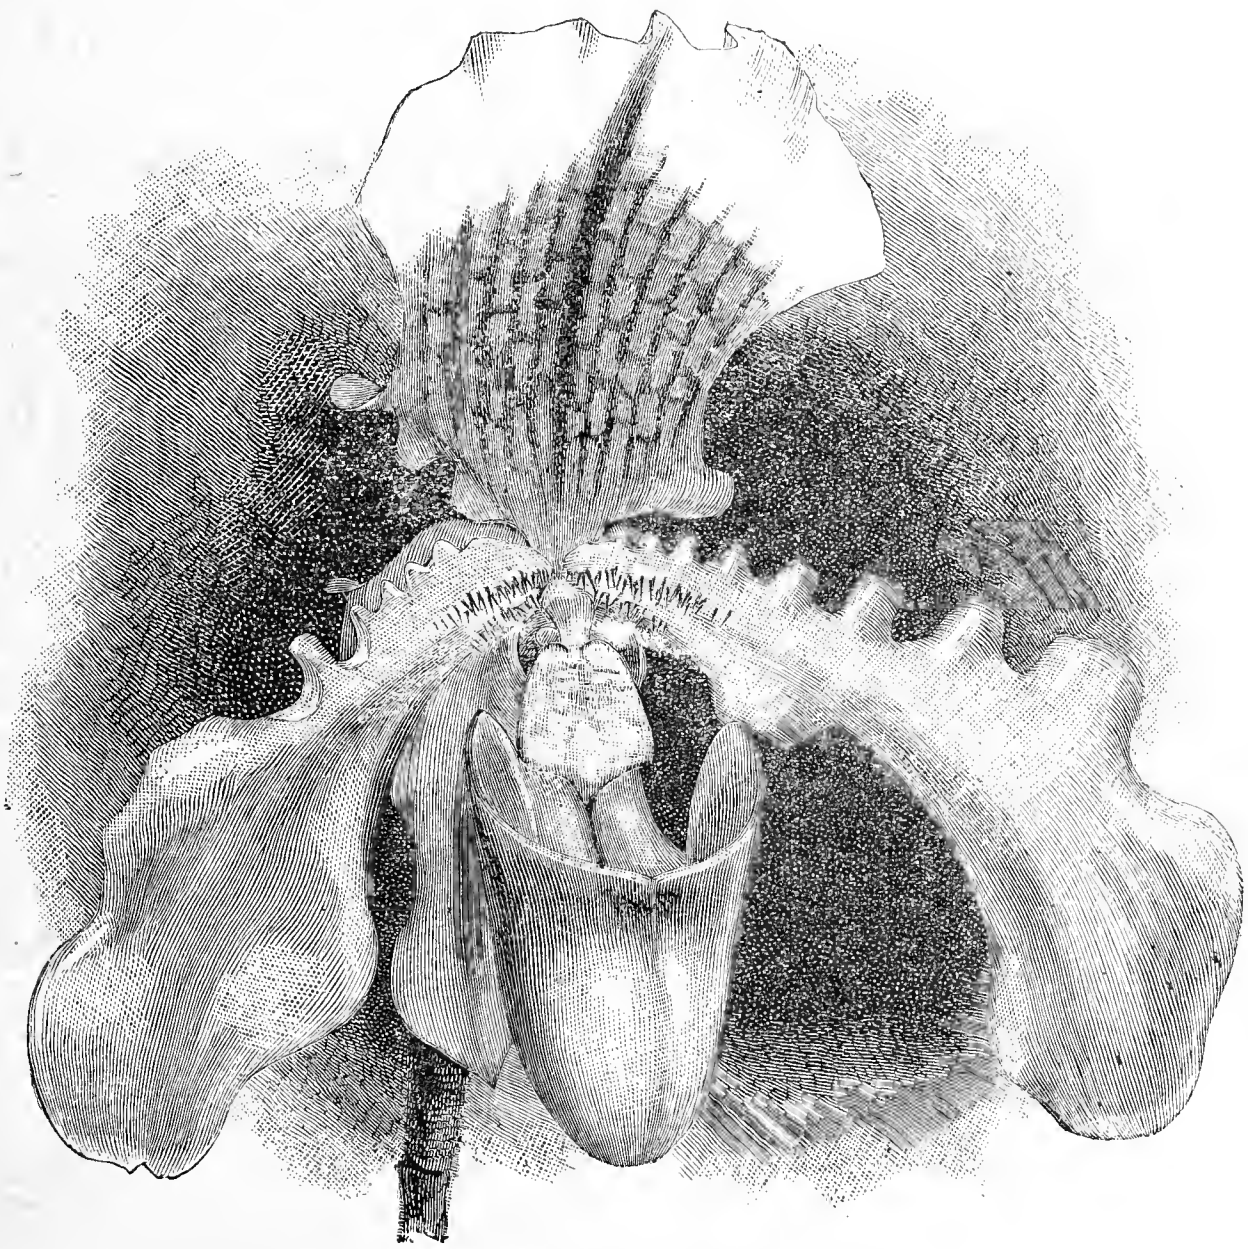

Fig. 58.—Cypripedium hirsuto-Sallieri.

Dendrobium Phalænopsis Schroderianum.

I have posted you two sprays of Dendrobium Phalænopsis Schröderianum for your inspection, thinking they might interest you. The plants we find to be of most easy culture, and are throwing from two to three spikes of bloom to each new pseudo-bulb. I grow fifty plants, and they are now a grand sight.—F. Ashman, *The Gardens, Billing bear Park, Wokingham.*

[We were greatly interested in the spikes of Dendrobium Phalænopsis with which our correspondent favoured us. They were of exceptional length, and the several flowers were beautifully coloured. In form and size the individual blooms compared very favourably with any we have seen. We are much obliged to Mr. Ashman, and are of the opinion that the details of his system of culture would be read by contributors to the Journal with pleasure. The procedure must be good, or such spikes could not be produced.]

Odontoglossum grande.

Had Mr. G. Ure Skinner done no more than discover and introduce this fine species to our gardens he would have rendered a great service to horticulture. It was one of the first Orchids I ever saw in flower, and every season as it comes round increases my admiration for it. A fine specimen I had under my charge in the West of England filled a pan about 15 or 16 inches across, and annually produced five or six spikes of flower. In general appearance the plant is so well known, and the blossoms are so universally admired, that little in the way of introduction or description is necessary. In short, then, it is the largest flowered, the most brilliantly coloured, and most generally useful Odontoglossum in existence, and looking at the number of beautiful plants this favourite genus contains, this is praise indeed.

Its cultivation differs somewhat from that of the crispum, triumphans, and similar sections of the genus. It delights in a rather higher temperature than either of these kinds or their varieties, but, like them, delights in abundant moisture. Its habitat is described as "dark ravines near Guatemala—in situation where it is secure of moisture and abundant shade." But in the usual Odontoglossum house, if this is kept as it should be for the truly Alpine kinds, there is not much fear of O. grande getting too little shade. Indeed, it is more than likely that in nine cases out of ten it is far too heavily shaded to get the best results. It is true the sun must not be allowed to shine on the young leaves and growths, but when these are fully developed and the blossoms past there is no doubt a little sun helps to consolidate the whole system of the plant, and prepares it more thoroughly for its winter rest.

There are in many places ferneries kept at about a greenhouse temperature, fairly heavily shaded during the summer, and kept moist; but in autumn, when the Ferns have finished their growth, or nearly so, more light is allowed. These are ideal places for O. grande, and in a few seasons small bits make fine handy specimens, that from now onward until Christmas may be depended upon to keep up a fine show. Several plants here in 5-inch pots are carrying a dozen and upwards of the characteristic flower, the effect of which when grouped with some of the fine forms of Adiantums, is very fine. In arranging the plants it is wise to let a little of their natural foliage be seen, as this greatly helps the effect.

With regard to the treatment of the roots, their appearance is the best guide to the class of compost needed. It will be noticed that these are considerably larger and more fleshy than those of the plant with which I compared them above, and consequently they require a rougher and very open make-up of material. A clean, well-dried peat, broken in lumps about the size of a pigeon's egg, and fresh green sphagnum moss, in equal proportions, suit the plant well; but as this of itself would run very closely together, plenty of rough material, as potter's ballast, charcoal broken in lumps, or rough crocks, should be added. About two-thirds of the depth of the pots used should be filled with drainage, the remaining third being ample room for compost.

As the roots are fairly strong a pot at least 2 inches larger than the plant every way should be used for large specimens; for smaller ones the margin should be comparatively narrower. In removing the plant from the old pot care is necessary to detach the roots without injury, but is well repaid by the difference in plants so treated and those roughly handled. Any chance bits that may be decayed should be cut out clean, and also the greater portion of the old compost. Often the roots come away with pieces of charcoal or crocks attached, and it is important that these are not severed if it can possibly be avoided. If the pseudo-bulbs are at all crowded and riding on each other a few of the oldest and weakest may with advantage be removed, but never cut away one bearing foliage or one likely to produce a

sound back break. Set the base of the plant well up, and finish off the compost neatly and firmly.

The new material will be found to dry very rapidly at first, and in consequence a good deal of water has to be applied. But it must not be overdone, or the compost gets sour, and the fresh young roots will not enter it freely. When growth is active the plants must be watered almost daily if properly potted and well established; but when the flowers are past, and the plant at rest—for this Odontoglossum has quite a distinct resting season—less will suffice. By no means dry the roots or allow the bulbs to shrivel, but make a distinction in the two seasons. In a properly balanced temperature insects are not usually much trouble; but sometimes scale put in appearance. When first seen let the plants be well sponged leaf by leaf, and continue this until they are thoroughly clean. As noted above, this plant is a native of the vicinity of Guatemala, whence it was introduced in 1839, and flowered for the first time in this country two years afterwards at Woburn.—H. R. R.

IS GARDENING DECAYING?

In a multitude of critics there is—confusion. Full cry, indeed! I should think they are; but, after all, there is very little wool. I am not quite sure in what order I ought to deal with them; so, in the words of wise old Will, I'll stand upon no order at all. Perhaps I am here suggesting a dangerous parallel, since his heroine's mental state was not of the soundest when the adjuration was laid upon her, and she got worse instead of better later on. But I am not quite "gone" yet, and there will have to be a good deal more pungency, as well as cogency, in future rejoinders than in those in the issue of October 7th before my mental balance is disturbed.

The Grapes and their Apologist.

There is such a charm and delicacy of touch in the work of one literary artist that I think he fairly claims first attention, and I hope both he and everybody will perceive at a glance that I am nothing if not fair. This artist, "A. D.," in his sweet and pleasant way, refers to me as a "croaker." Was this correspondent so absorbed in his new character of apologist for Grape growers as to forget that an epithet, however carefully selected, is not argument? Truly, when I bear in mind his recent performances I ought to feel how seriously I have vilified British Grape growers. Anyway, nobody, it is clear, is to blame. What matter if our exhibitors cannot get their bunches to the show without dividing them into sections (like Nile boats) and then putting them together again? "A. D." comes along and proves that all is as right as right can be. As a matter of fact, you only have to look at it in the proper way and you see at once that far from gardening being decaying it is taking on new attributes. Shades of Dickson and of Henderson! What a great honour it must be for these Grape mechanics to be made to shine so brightly under the limelight turned on by the gentle "A. D.!"

The Palace Grapes and "A. D."

But "A. D." has another rod in pickle for the croaker. He shows by the apologetic attitude which he assumes towards them that the Grapes at the Crystal Palace were not what they should be. This might be assumed, without any undue straining of the significance of facts, to be something in the nature of a corroboration of the croak. But not at all. "A. D." triumphantly proves that no weight whatever should be attached to it; indeed, it might almost be imagined that it was a matter for congratulation all round. To employ plain words, his remarks are either a tissue of trivial excuses or else a serious reflection on the good sportsmanship of our Grape growers, and of their loyalty to the leading Society. In the old days our best exhibitors were not such ignoble money-grubbers as to hold aloof from representative shows because the prizes were small. They fought in no small degree for the credit of themselves, their craft, and their country. Has the fever of the gold-hunter spread itself over horticulture? Do we look for a De Beers mine under the roof of the Drill Hall, and a Klondike in the grounds of the Crystal Palace?

The Mutual Admiration Association.

A cool old rider is "Melton." He has no doubt been over a fence or two, and a spill more or less is of small consequence. He thinks me a little hard in girding at the Mutual Admiration Association into which gardening has, in my opinion, resolved itself, but he does not forget to turn the phrase against an opponent. A Mutual Admiration Association of one! How now, "H. D."? Prove that the thing which exists in the unit does not exist in the whole, and you will do horticulture a service, as well as bring down confusion on my offending head. Perhaps you would prefer to suggest that there is no whole and only one unit—the aforesaid "Melton." It would do just as well for me; but I cannot take the Mutual Admiration Association with the same ease that he does. It is an obstacle in the way of real progress, and it might have for its motto an ancient couplet (slightly altered):

> Be to our faults both deaf and blind, in need;
> And to our merits very kind indeed.

The Classes and the Masses.

It occurs to "Chrysanthemum Lover" as a triumphant refutation of my contention that gardening is decaying to advance the spread of flower culture among the dwellers in our great towns. What on earth has that to do with the matter? I am not going to deny the obvious fact that the population is increasing, nor the equally obvious one that with more windows we have more plants. But these people are not gardeners, and what is more, the millions of plants in towns are produced, not by swell gardeners who hob-nob together at shows, but by plain plodding workers whom you never hear praising each other or extolling their own abilities before the world. It is the work of the classes, not the love of the masses, of which I lament the decay. I rejoice to think that the love of flowers is spreading amongst the people as much as I deplore the decline in the standard of professional work, broadly speaking, because, of course, I know there are exceptions—a fact I hardly thought necessary to explain to intelligent men.

The Decorations Question.

I beg to put "Chrysanthemum Lover" a plain question. In the garden which he managed, and in connection with which decorations "on a gigantic scale" were carried out, was there the full round of customary gardener's work? I mean, were there the customary ranges of vineries and Peach houses? were there Cucumber and Melon pits? was there a kitchen garden with fruit walls? and had "Chrysanthemum Lover" charge of them all? I ask these questions because in quite a number of places that I have visited of late years there have been such reductions in other departments as to far more than balance the extra decorative work; and I put it explicitly because on the answer to it depends the entire position. I know of more than one place where the "decorative" man has no fruit to grow at all, but he grumbles as furiously as if the supply of Covent Garden itself was upon his shoulders. If his excuses are not "lame," whose are? As regards "Chrysanthemum Lover's" other remarks, perhaps it will suffice if I set the first line of his second paragraph against the last line of his fourth. Here they are in all their consistency:—

(1). "Is gardening decaying? Certainly not."

(2). "This has been the cause of the serious deterioration in gardening in many places."

Traveller's Tales—and Retorts.

Yes, "Vespa!" I am quite prepared to point the way to better things, and to begin I will venture to give a little lesson in grammar. I cull the following delicate blossom of composition from his second paragraph:—"What would he have when, in flinging down the gauntlet, from the 'rock bed of unassailed accuracy?'" Where is the sequence here? There is no finish to the sentence. If "Vespa" had left out the "when" I could make something of it; as it is I can make nothing. If he will give me the benefit of grammatical criticism I will answer him; in the meantime, this lapse, coupled with some recent criticism on the spelling of fruit names at the Palace Show, suggests one direction in which gardeners may hope to achieve "better things."

The Threatened Boycott.

For a dignified answer to an honest criticism commend me to "Cedo Nulli." He retorts upon me by threatening to give a warm quarter of an hour to the next unfortunate "commercial" who steals tremblingly into his autocratic presence. It would appear from this that "Cedo Nulli's" only conception of a traveller is the man who comes along with an insect wash or a new plant, and because a traveller of another sort, one who moves from place to place, even myself, records the result of observation, the poor commercial is to be snubbed. Not only so, but others are to be punished. Imagine an agent for a "Critic's Educator," "Florists' Instructor," "Gardeners' Dictionary," or any other valuable work approaching "Cedo Nulli!" Author, artist, printer, publisher—all are bundled off unceremoniously in the person of the miserable agent. Is this justice, as administered by the modern gardener? And if it is, what about fair play? Is that decaying, too?

Belated.

I should like to explain to those of my opponents who honour me with attention in various ways, that I cannot always keep up to date in returning the compliments they shower upon me. Many, and often long, journeys forbid, and rests protracted enough for writing are only occasional. The life is, perhaps, on the whole no better than was spent in the days of growing and showing, potting and pruning, digging and decorations, and other items in the gardener's life, but one sees and hears much. Then, in addition, liberty is sweet, and the "crumbs" picked up by the way would be sweeter but for that novelty to gardeners—the income tax.—Traveller.

The several articles which have appeared of late bearing on the decadence of gardening have awakened much interest among the hosts of Journal readers, and although, no doubt, there have been many truths advanced, there is undoubtedly some suspicion of exaggeration in other cases. The contribution by "Chrysanthemum Lover" (page 344) was no less interesting than some other previous articles, and contained many truths concerning the present and past state of gardening.

Your correspondent truly says that gardening is not decaying, but changing in form. In how many private places now is there not some competition with the market men, and this, too, on a reduced staff to carry on the work? This may not be true in the case of smaller gardens surrounding provincial towns and cities, but in large country seats, where incomes are derived mainly from the land, there is this restriction of labour and capital, and a larger output demanded to help to maintain it. In the face of such surroundings, how can gardening in its true sense be carried on? and how can fruit trees on the open walls be trained to the perfection that obtained in the olden days?

There are some gardeners even now who take great pride in their wall trees and make them their hobby. When a gardener has to carry on the work of a garden with one or two men, how can he be expected to have the same smartness as his predecessors of some thirty or forty years since, when twice the number of men were employed to do the same work? It it is an obvious impossibility, and if wall trees must be trained as they were then, something else quite as important must be neglected. My aim has been to try and keep everything under my charge as presentable as circumstances permit without spending unnecessary time on one object at the expense of another

I am quite prepared to admit that a well trained tree is an object of which a gardener, whether he be head or subordinate, may well be proud. The methods adopted now scarcely compare with those of forty years ago; then the object was to build up the tree slowly and perfectly from its base; the more modern system is to furnish the walls in the shortest space of time, and this express method, if it may be so termed, is only a repetition of what occurs daily in other phases of gardening. In many gardens a man was employed expressly for the wall and other trees; very little work beyond that was expected of him in favourable weather; at the present time, and for several years past, this appointment has become obsolete, and yet there are the same number of trees demanding attention from the existing staff, and the best has to be made of the altered circumstances. Unfortunately this is only one out of hundreds of similar cases; but in spite of this I hold that gardening is not a decaying industry, or how can the support of the numerous flower shows, both summer and Chrysanthemum, increase as they do year by year?

"H. D." was taken to task because he advanced decorative work as one reason why fruit trees had less attention paid them outdoors. This explanation is certainly reasonable enough, for certain it is that such work requires much preliminary preparation and study, when it has to be carried out in a large way; and I should say it is a lame argument to snggest that this, and every other extra class of duty that modern times demand, can be done by a limited staff without a corresponding loss to some other department.

Because fruit trees are neglected outdoors on walls, from "Traveller s' point of view, everything else suffers proportionately. No credit is given for Peaches, Nectarines, or other fruit grown under glass; but, judging from inferences, under-glass cultivation is taken to represent an easy-going method, bearing no comparison with outdoor fruit. In the case of Peaches, Nectarines and Figs, or even Pears, Plums and Cherries, who would not grow them under glass protection if they had the means of providing it, to change what might be an uncertain crop into a reliable and unrisky one? Glass cultivation of fruit evidently is taken as representing the decadence of gardening with such as "Traveller," but he will have to write an additional letter or two to the *Journal of Horticulture* before he will carry conviction into the minds of many of its readers, in bearing out such views.

There is another aspect which does not seem to have suggested itself to those who believe in the decay of gardening, and that is the advancement in education, and the greater facilities for learning through the Press. If gardening decays to the extent that is set forth, what becomes of the teachings of the many excellent weekly periodicals, why are they published, and what good do they do if we profit nothing by them? Really the more one reflects on the theme the more monstrous does it appear that gardening, more than any other industry, should be considered not only stationary, but decaying, and this simply because less time is spent on wall trees than was the case forty ago.—A COUNTRY GARDENER.

AMIDST the forces of present day gardeners "Traveller" has fired a shell, and so jubilant is he of his success in silencing the whole army, that he rushes hastily into print, and endeavours to show the horticultural public the soundness of his statements, and the fallacy of any argument in contravention thereof. The fraternity flinches, says "Traveller," from the challenge he has given them, and silent are the men who at shows may be heard laudating their own handiwork.

For how many years "Traveller" may have been watching the decay of gardening we will leave for future consideration, but seeing he claims the temerity to speak what he thinks, why has he not the courage also to disclose his name and whereabouts, when we should probably be better qualified to judge of his experience? Some of us really have more than a year's experience, and if these form the congregation of talkers and writers among whom the shell has dropped, let me assure "Traveller" that, although the company stand amazed and astonished at the great detonation, they are not, as he would have us believe, absolutely driven into the mysterious future, as they will now be found willing and able to maintain their claim to the position of men possessing sound general horticultural ability.

I am not one of those who would allow to sink into insignificance the fact that in the old days there existed men of good general horticultural experience. No, I respect too highly the doings of many who have gone before, but must remind "Traveller" that, where in those days there lived one gardener of superior ability, to-day there may be found ten. Does this assertion savour of decay in gardening?

How many present day gardeners can we find possessing the knowledge to grow all they require for decorative purposes—aye, and have the ability to arrange the same in the most artistic styles? Did "Traveller" ever experience better grouping at shows, more artistically decorated dinner tables, or taste better flavoured fruit and vegetables? Has the gardener of to-day not to maintain in quite as good condition as formerly the flower and kitchen gardens, as well as the ornamental grounds surrounding his employer's abode, to say nothing of present day furnishing, an experience in which "Traveller" lays claim to possess more than ordinary ability?

Probably whilst championing the cause of all-round gardening, he would have us believe that in the old days, when glass structures were heated by the aid of brick flues and the scythe took the place of mowing machines, that those were the days when good all-round gardening was accomplished. Without the least intention to cast reflection upon those ancient horticultural appliances, in the company of which many of us have spent numerous happy days, we acknowledge the advantages of modern science, and can assure "Traveller" of our ability to work with either.

It is said that the growing of wall fruit is neglected that Chrysanthemums may have attention. "Traveller," perhaps, would be afforded a little gratification if, when going his rounds, he visited some establishments where Chrysanthemums claim a goodly portion of the gardener's attention. to witness the condition of the wall trees and the fruits thereof, would probably be to see evidence of the fact that even this particular branch does not escape the gardener's care. A collection of Orchids would probably be more appreciated by "Traveller;" and whilst acknowledging the pleasure afforded to many in this respect, there still remains the contention that we have Orchid as well as Chrysanthemum specialists.

That the extended cultivation of the "autumn queen" has stirred up admiration and interest amongst many at a very dull season of the year, and that a national horticultural industry of more than ordinary importance has resulted therefrom, is a fact over which "Traveller will do well to ponder; and he will realise another fact – that the cultivation of Chrysanthemums is not, as he would have us believe, on the decline, but in the ascendancy.—J. P. LEADBETTER, *The Gardens, Tranby Croft, Hull.*

SILICO-FLUORIDES IN HORTICULTURE.

IT does not seem to be generally known that in fluorine we have perhaps the most efficient of all germicides. For some reason, which is at present unknown, all lower organisms seem to be totally incapable of resisting its action, and it is not impossible that in course of time it may prove to be one of the most important of all the elements in respect of its utility to man. It occurs in nature combined with calcium, and from this substance its compounds are prepared; most of them are solids. The fluoride of potassium is extremely soluble in water, but most other simple fluorides are somewhat insoluble.

On a general review of the possibilities connected with fluorine, it has seemed to me that its characteristic effects would be most generally available in horticulture if a silico-fluoride was employed, and of these the silico-fluoride of ammonium seemed to be the most advantageous. This substance is a solid, easy to produce in a state of purity, and readily dissolving in water, with which it forms a solution having a specific gravity of 1·101 when saturated. The effect of spraying plants infested with aphides and other pests with a very weak solution of the silico-fluoride of ammonium is not only immediate death to the insects, but when the substance is eventually washed off the plants into the earth it decomposes there, liberating ammonia very slowly at their roots; so that in addition to destroying the insects it is also valuable as a manure.

The silico-fluoride of ammonium is not at present known in commerce, but no doubt if a demand for it sprung up it could be manufactured and sold for about 20s. per cwt. Meanwhile I shall be glad to send any of your readers, who would like to experiment with it, a certain small quantity in time for next year s operations. If, however, they would prefer to make it themselves the following method of manufacture may be adopted. Equal quantities of hydrofluoric acid and rain water are treated with excess of fine silver sand; the mixture is made in a leaden vessel and stirred up occasionally for a month or so. At the end of that period it is filtered from the sand, almost neutralised with weak ammonia, and evaporated to dryness.—W. MILLS, 14, *Westbourne Road, Forest Hill, S.E.*

[Mr. Mills has informed us that he is not a manufacturer of anything he has mentioned, his only object being to find "something superior to Bordeaux mixture and other foreign empiricisms" for use in British gardens; and as he thinks it desirable that silico-fluoride of ammonium should be tried against different garden pests by different persons, he is willing to send samples for that purpose. Stamped directed envelopes should be enclosed with applications to the address given.

Relative to the home manufacture described, and fearing the possibility of danger in using hydrofluoric acid, we consulted an eminent agricultural chemist, who has devoted especial attention to the question of insecticides and germicides. He favours with the following observations on the subject generally:—

"The point raised with regard to *silico-fluorides* is interesting. The material suggested is not new, and some years ago I had intended to try it as a remedy for Hop mould, but found other and more suitable material. I find on reference that the use of silico-fluorides has been patented by W. Thompson, and that it has been taken up for application to calicoes, and for precipitating sewage. It has also been suggested as an antiseptic in surgical operations. Although I have not actually tested it, I believe the material suggested by your correspondent is possessed of no insecticidal value apart from its *acidity* and its consequent danger to the plant.

"As a fungicide, it may be of service, but it has certain grave practical drawbacks. It requires pure, soft water, and cannot be mixed with soap. Anyone who has used washes knows how essential 'lathering-power' is

to the successful working of a plant remedy - a plain solution beads off the mycelium growth or the bodies of the insects, and does no adequate execution.

"The potash salt is sold in commerce under the name 'Salufer,' as an antiseptic of similar application to boric acid and borates. Your readers should be warned *not* to make it by the method suggested. Hydrofluoric acid is frightful stuff for the most careful person to deal with, let alone a gardener. I know a man who lost two fingers through accidental contact with the acid.

"Silico-fluorides can be made very cheaply by roasting Derby spar, sand, and charcoal, and leading the gaseous product into water. It is then neutralised with the alkali or base, and evaporated down to dryness.

"With regard to the suggested inferiority of Bordeaux mixture, it should be noted that nothing has yet been found to equal it for dressing Vines, Potatoes, and other plants against fungoid attacks, and that owing to its adherence to the foliage it acts as a preventive for weeks, while the silico-fluoride, at best, could only destroy such fungi as it encountered at the time of application.

"My opinion is that silico-fluoride is not suitable for garden use, though perhaps a serviceable antiseptic for other purposes. I also advise you to warn gardeners that no reliable evidence is yet to hand that the stuff is either effective or non-injurious, two fundamental requirements of a garden remedy."

Mr. G. Abbey says he "knows fluoride of potassium to be a powerful fungicide and insecticide, very deliquescent and soluble in water, one part in 1000 parts water acting promptly and effectively on germs." He has "not tried silico-fluoride of ammonium $(NH_4)_2S_2F_8$, but thinks it ought to prove what Mr. Mills claims for it as a germicide and fertiliser." Mr. Abbey must try it. We are glad in being able to put both sides of the question before our readers, and leave those of them who desire to do so to test the product for themselves.]

CEANOTHUS.

The value of the various species and varieties of Ceanothus for the ornamentation of gardens can hardly be over-estimated. Some are first-rate shrubs for covering walls, others are useful for beds or groups, while a few grown in pots will be found very acceptable for conservatory work. When grown on a wall, two or three species are among the first of early spring shrubs to flower. Others flower during summer, whilst a few reserve their energies to make a grand display for fully three months during late summer and early autumn, a time when really good flowering shrubs become scarce. Most of the Ceanothus which are in general use are very showy. The flowers are produced with great freedom, and vary in colour from white to blue of various shades, and also tints of pink. The only objection that can be raised against the extended cultivation of these handsome shrubs is that several of the species are rather tender. The latter, however, can be grown against a wall, and by this means escape uninjured through all but the most severe winters.

The most useful for general cultivation are C. americanus, C. azureus, C. Arnoldi, C. divarieatus, C. papillosus, C. rigidus, and C. Veitchianus, together with several very good garden varieties of C. azureus. Of these the three former with the varieties of C. azureus are the most hardy. C. americanus is a native of the Eastern United States, where it is said to cover large tracts of land, and make a splendid sight when in flower. It makes a moderate sized bush a few feet high. The white flowers are upright and cymose, resembling very much a branched raceme, but individually are small. The flowering period is from the end of May to the end of July. In North Ameriea this plant is known as the "New Jersey Tea," the leaves having at times been used as a substitute for that beverage.

C. azureus (with its varieties) is possibly the most useful of the genus from a horticultural point of view. It has larger foliage than C. americanus, and also larger blooms. The flowers are light blue and produeed with great freedom. The varieties are chiefly of continental origin, and are for the most part very beautiful, and superior to the type. They vary greatly in colour, the majority being of various shades of blue. Possibly none is better than that known as C. Gloire de Versailles. The foliage of this is in shape similar to that of the parent, but larger, many of the leaves being 4 inches or more in length by 2 in width. The growth is stronger than the type, and the infloreseences are correspondingly large, many being 6 or more inches in length. The flowers are bright blue. It commences to flower early in June, and continues until frost stops the growth in autumn.

Several of the other varieties have equally good flowers and strong growths. C. Arnoldi is of a pinkish hue and is very free blooming during late summer and early autumn. For this section, especially the varieties of C. azureus, it is advisable to put a good layer of dry leaves about the plants on the approach of severe weather; this will give them a much better chance of coming safely through the winter. In spring they should be pruned back fairly hard.

Those mentioned for growing on walls are quite distinct from those recommended for the open, and also from each other. C. rigidus is the earliest to flower, and possibly the richest coloured of all. In a mild spring the earlier flowers begin to open about the third week in March. The young growths are very stiff. The flowers are a dark, rich shade of blue, and are produced from almost every joint of the young wood, making the whole shoot a spike of blossoms. C. papillosus flowers a month or so later than C. rigidus. The flowers are light blue, and produeed in loose racemes. C. Veitchianus appears to be more tender than either of the others. The flowers are pale blue. It can be grown well in pots, and makes a good plant for the greenhouse.

C. divarieatus is the hardiest of those mentioned for walls, and can be grown in the open, but does not flower so well as when grown on a wall. It branches freely, these being thin and pendulous. The flowers are pale blue, and it is at its best about the middle of April.

A fairly rich, lightish loam is suitable for all mentioned, and with the exception of C. rigidus each may be rooted fairly well from cuttings. C. rigidus requires layering. It is as well to keep a set of plants in small pots of the tender kinds, so that they can be given proteetion in case very severe weather is experienced in the winter. All will stand moderate winters well; but by keeping plants under cover a stock is insured in case any of the plants are killed by a long spell of frost. Although they require a little more eare in winter than some other shrubs, the trouble is well repaid by their exceptional beauty when in flower.—W. D.

HINTS ON WATERING PLANTS.

I read with much interest "T. D.'s" capital article on potting, which appeared on page 298 of the Journal, and I feel constrained to offer a few remarks to supplement it, if I may be allowed to do so, on the watering of plants. I readily admit and agree with "T. D." that the judicious potting of plants is one of the most important operations we have to deal with, and in my opinion the proper watering of them should rank as another equally essential point in the successful cultivation of all kinds of plants in pots.

Observation more than justifies me in saying that a great number of our young gardeners do not realise the necessity for that close attention and watchfulness which each individual plant under their charge requires, and I think we may place some portion of the injudicious watering of plants to want of thought and close observance.

Many times have I seen young men in charge of a collection of plants kick the pots when standing on the ground of such plants as Chrysanthemums, Azaleas, and others which are placed out of the houses for the summer months. Now I defy anyone to know by this dilatory test whether a plant is in need of water or not. I have always found the safest and most efficient method is to rap the pots smartly with the knuckles, or in the case of plants (especially valuable specimens) growing in houses to lift them bodily, and so judge by their weight. This system cannot be too strongly recommended in the cultivation of greenhouse plants of every description, for with few exceptions these are delieate rooted. To insure success the cultivators ought to keep in mind the conditions under which the various plants exist in their native country, and following a course of proeedure as nearly allied to Nature as circumstances will permit.

I well remember some years ago (in the absence of my chief) showing a gardener of note through the houses, when he observed a journeyman testing and watering plants by the system I have described above, and he made the following remark:—"Ah, young man, it is a pleasure to see that method of watering; it is a safe one, and one that now (unfortunately) is seldom praetised."

Every collection of plants ought to be closely looked over every day, and those that require it should be properly watered—*i.e.*, given sufficient to thoroughly moisten the whole of the soil in the pot. If the pots are too full of soil, as sometimes happens, the operation should be repeated until such times as the water has thoroughly permeated the whole mass. In the case of large plants, which may be standing on a slate slab stage, it is a good plan to elevate them on two pieces of well-seasoned wood of about 1½ inch in thickness. This simple plan has much to recommend it. First, it allows for a free circulation of air to pass under and about the pot, thereby keeping the roots in a healthy state; and second, when applying water the operator is apprised when the plant has had sufficient by the water passing through the drainage of the pot.

To conclude these few remarks I would urge all young gardeners to thoroughly digest "T. D.'s" article on the judicious draining and potting of all species of plants under their charge, after which they may with advantage read and follow the simple directions here laid down, always remembering that these are by far the most important operations connected with the cultivation of plants in pots.—Epacris.

Fantastic Summer Bedding.—The note on this subjeet by "A. D." on page 362 is to the point, and in warning British gardeners against this class of thing he is giving them good adviee. The pictures, or some of them, have not even the charm of novelty about them, and anything more ridiculous it would be difficult to conceive. That there is need for "A. D.'s" warning the following will show. I have just returned from a visit to a pretty old garden in the neighbourhood, where there are many grand old herbaceous plants and shrubs, some pretty bits of underwood, and other interesting features. The gardener stopped at a pretty part of a hardy fernery, from which the lawn sloped away to a piece of ornamental water. "I have planted this piece of turf with Snowdrops," he said. "Oh, indeed; they are very pretty I should say in spring." Then it came out that they had been planted to form the initials of the proprietor and the name of the plaee. And this in, perhaps, the pleasantest bit of the whole garden. What the proprietor had to say about the arrangement did not transpire, but tastes differ, and possibly he approves of it.—H. R. R.

COMBE ABBEY.

WARWICKSHIRE is rich in memories of bygone days; its people are proud to have produced that splendid genius the "Bard of Avon," whose memory the whole world delights to honour; they are proud, too, of the grand old castles, abbeys and monasteries with which their verdant county is richly endowed. Combe Abbey—the seat of the Earl of Craven—is one of the most extensive among them; it covers an enormous area, and the following particulars concerning it I glean from "Kelly's Directory:"—"Combe Abbey is situated two miles north from Brandon Station on the London and North-Western Railway, was erected on the foundation of the first monastery of the Cistercian order settled in this county, in the reign of King Stephen, by a grant to the Abbot of Waverley, in Surrey, by whose monks, therefore, this religious house was established A.D. 1150. In 1616 it came into the possession of Sir W. Craven, who was Lord Mayor of London in 1611, from whom it is descended to its present noble owner. In 1864 the work of complete restoration, or more correctly, a rebuilding of the Abbey, was begun, the Norman style of architecture being maintained at the base, changing in the upper stories to that of the thirteenth century. The gardens projected by William, second Earl of Craven, were very extensive, occupying an area of upwards of 40 acres, and were laid out by Mr. W. Miller, the well-known head gardener and sub-agent." To these gardens I lately paid a visit in the company of a horticultural friend, and the following briet notes are intended to convey a few of the impressions formed during a pleasant — but far too short—September afternoon.

After leaving the main road from Brandon Station we began to traverse a drive which led straight as an arrow up to the quaint old Abbey. This drive must be well nigh two miles in length. At its beginning a shady bower is formed for some distance by a stretch of woodland on each side; further on the view widens into an open expanse of park, which extends to a great distance in some directions and narrows down considerably in others. The drive through this park is bordered by lines of trees; some of them are gnarled old giants which have withstood the storms of ages, others are young, having been planted to fill up gaps. When some distance from the Abbey we diverge to the right, pass lawns, shrubberies, and well-trimmed Yew hedges, till the kitchen gardens are reached, where we find Mr. Miller ready to welcome us beside his pleasant home.

No time is lost before we begin the work of inspection, for it is apparent at a glance that the gardens, like the Abbey, are very extensive. In front of Mr. Miller's house the kitchen garden and glass structures are situated. The former is a model of what a good kitchen garden should be, for the situation is open, the walls substantially built, and the walks well arranged, one wide one running through the entire length and a water tank forming the centre. Four acres are thus enclosed, but many vegetables are also grown in other quarters. The ground is in all directions closely cropped and in a clean condition. We noticed splendid crops of Celery, Spinach, Turnips, Lettuce, and Cauliflower advancing. There should certainly be no lack of these to satisfy all parties in due season. The principal range of fruit houses, about 380 feet in length, is built against a wall, which, instead of being due south, is slightly inclined to the east, a situation which Mr. Miller favours, as he believes in the early morning sunshine and a long afternoon for syringing and watering, after the full force of the sun has left the houses. After entering these houses it does not take long to discover that Mr. Miller is a fruit grower *par excellence*, for where the crops have already been gathered we find healthy Vines, with hard nut-brown wood, or Peach trees with clean foliage, thinly disposed shoots, and shapely form. The back wall of the whole of this range is covered with such useful plants as Oranges, Lemons, Passiflora edulis, Monstera deliciosa, Camellias, and several uncommon plants, which supply either fruit or flowers.

After passing through several compartments, from which the crops had been removed, we came upon a fine house of late Grapes, in it Lady Downe's, Alicante, and Gros Colman were in strong force—in fact, it is not often that the first-named variety is seen in such good form, as the bunches were large, shapely, and beautifully coloured. Passing onward we entered another house in which the Grapes were ripe. Our guide walked quietly forward, but said not a word. I looked at the grand bunches hanging on the Vines, noted their perfect colour, and for a moment hesitated as to what variety it was. Closer inspection soon revealed that they were Black Hamburghs, yet so large in bunch and berry as to resemble Gros Colman; indeed, on this point hangs a tale, told in true Scotch fashion by Mr. Miller. Here it is. A visiting gardener on entering the house some time previous to our visit, exclaimed, "Ah! a fine lot of 'Colmans.'" No reply from his guide. He looked again and again, till gradually it dawned upon him that the foliage was not that of Gros Colman, but of Black Hamburgh. A general laugh followed, then the tasting of a few berries, and the visitor's appetite for dinner was completely spoiled. I have seen many houses of fine Grapes, but have not met with so grand a lot of this variety for a long time, and I question if a better one could be found in Britain just at the present moment.

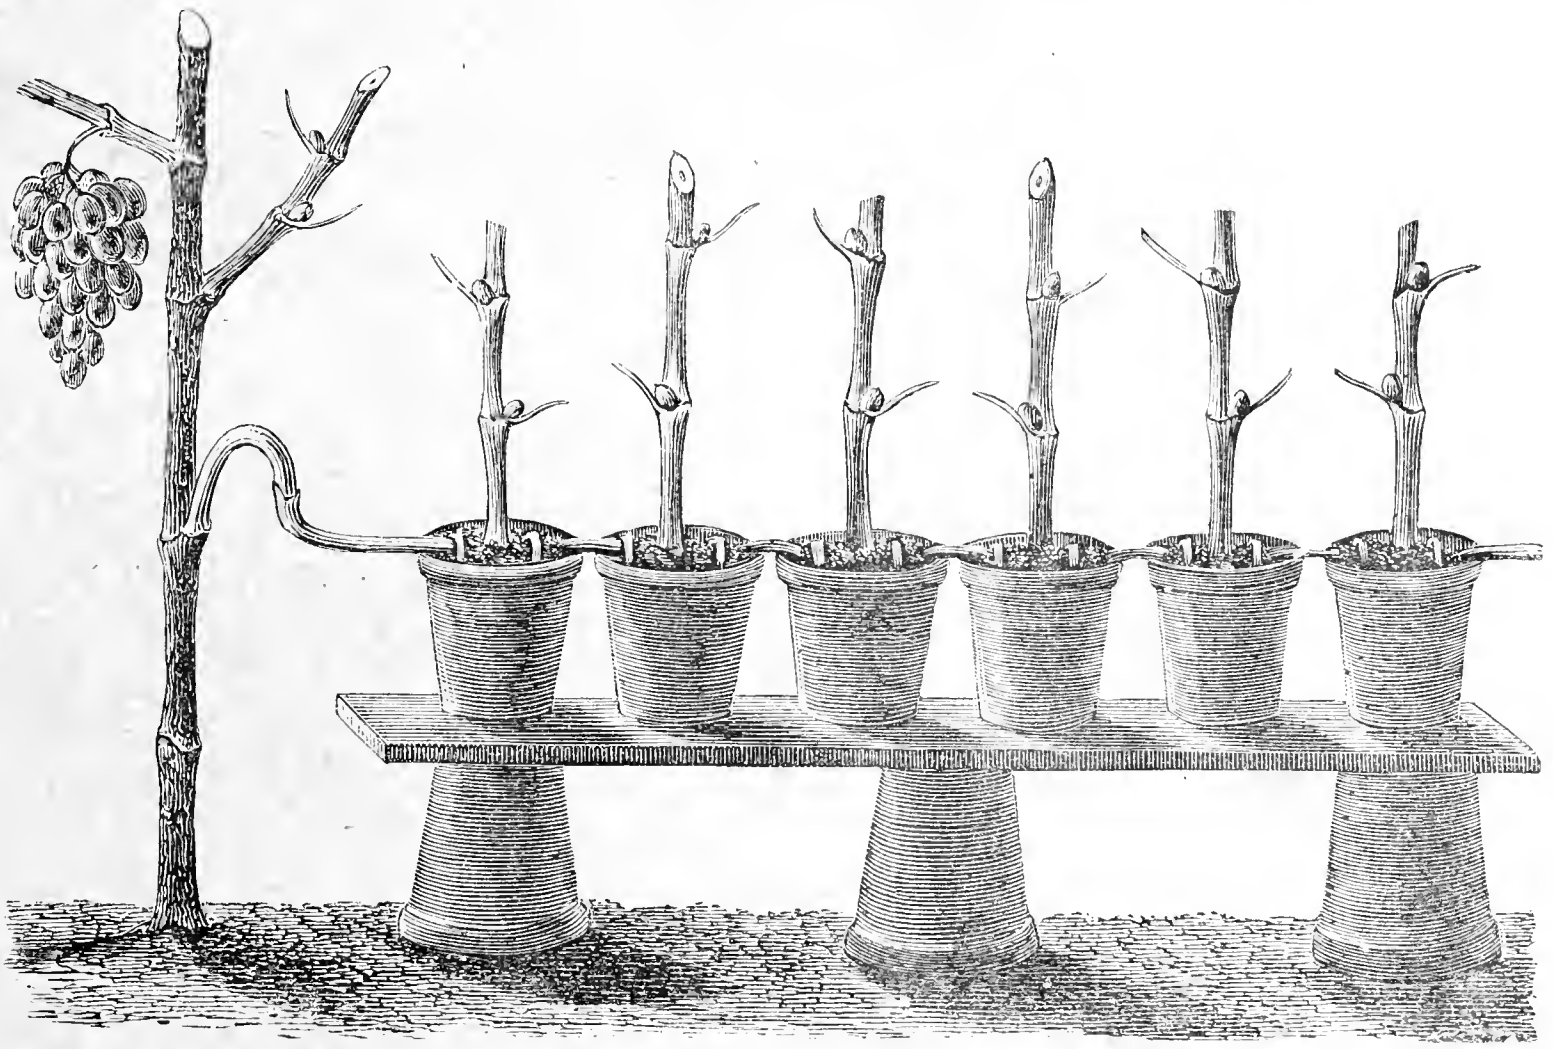

FIG. 59.—RAISING VINES AT COMBE ABBEY.

Mr. Miller pursues one practice which is very uncommon, although he has written about it years ago. It is this—the greater part of his Vine and Peach borders are covered with bricks or tiles. The advantages he claims for the practice are, that surface root-action is greatly increased, and that they are kept cool and healthy under the bricks. If these are removed in summer time white healthy roots may always be found in abundance. Another advantage which I can see in the plan is, that when plants are placed upon the borders there is always a good bottom to stand them on, and there is, therefore, no necessity to trample on wet soil after the borders have been watered. These bricks are removed in winter to give the border a dressing, the soil is then raked level, and the bricks simply placed closely together upon the surface. In some cases they are also again removed in April or May to give the borders a dressing of bonemeal or Thomson's Vine manure. Abundance of water right up to the time when the leaves fall is another cultural practice in which Mr. Miller has great faith.

Before leaving this part of my subject let me give a few remarks upon an "express system" of raising and fruiting Vines which has been successfully practised by the intelligent gardener-manager at Combe. I noticed several young Vines in 7 or 8-inch pots, each carrying a bunch of well-coloured Grapes. An inquiry elicited the fact that they were only about seven or eight months old, having been grown in the following way. A strong young rod along the front of one of the houses was selected for operating upon. Under this a strong plank was placed, supporting pots filled with good loam. The Vines were then notched under the buds, covered with moss, and pegged firmly into the soil (fig. 59). Roots were formed so quickly that each young Vine was severed from the parent cane six weeks from the date of pegging down. From that time they grew on uncheeked, pushing, as I have previously pointed out, strong canes and ripe Grapes.

I must say a few words upon the fine vigorous Peach trees growing in two old upright houses. These trees show to anyone that Mr. Miller knows the value of keeping shoots thinly disposed and free from insects. The style of training adopted is in most instances the "Seymour" one, but along the front of the house a novelty in the way of horizontally trained Peach trees may be seen, the system answering here as well as the usual method. It is, in fact, another illustration of the well-known truth that successful fruit culture is not a matter of following a particular style of training but of attending to all the details of culture in an intelligent manner. Strawberry plants in pots having plump crowns, such as the forcer delights in, occupied a sunny position in the open air, and I was pleased to see that grand old variety, Auguste Nicaise, among them. The plant houses are very numerous—in fact, there is quite a little town of glass at Combe; but there is yet so much to write about that I shall touch lightly upon them. The stoves are filled with a good assortment of plants of a useful size for decorative purposes, and I noticed some strong Bananas with huge bunches of fruit.

A very conveniently arranged fernery, with Orchids on the side stage, showed the latter plants are now being taken in hand, and I doubt not the collection will speedily increase in size. Several plants of those two fine early flowering Chrysanthemums, Mrs. Hawkins and Madame Desgrange, displayed their charms in a long lean-to structure, and useful they were for supplying cut flowers. Other houses were filled with Roses, Camellias, Azaleas, Callas, and some were being fitted up for the reception of bedding plants. Onward we press again, through the kitchen garden toward the mansion; but stop, let us look one moment at these long beds of Violet Marie Louise, grand indeed, having hosts of flowers fully developed, and showing great promise for a succession of fine blooms during the winter months.

We reach the Abbey, ascend the grand staircase, and look out of the windows on a lovely scene beneath and beyond. Below us a terrace runs round the mansion, grassy slopes are formed from this to the level stretch of turf in front, enlivened by flower beds worked out in a beautiful scroll design. Still further ahead is a magnificent piece of water, 90 acres in extent, bounded on one side by grassy banks, on the other by the park, while in the distance are acres of bog, with a luxuriant growth of Reeds. It will thus be seen that from the windows of the Abbey one looks down upon a true garden scene, in which bright colour, green grass, and water each play a special part; then, as the eye wanders in the distance, a view of wild grandeur is caught, the combination being one not often met with, and therefore characteristic of the place.

The flower garden immediately beneath the windows, from which the above view is obtained, is deserving of more than a passing notice, as it is of quite an original design, and was laid out by Mr. Miller during the spring of the present year. A straight gravel walk runs through the centre; on each side is a level piece of turf, oblong in shape. In this turf a scroll forming one continuous design is cut out, the turf on each side of the central walk being treated in exactly the same way. When well planted, as in this case, with suitable flowering plants, the effect produced is novel, striking and beautiful.

Hours might be pleasantly spent in wandering about the delightful pleasure grounds of this old English home, where stretches of grass and winding walks lead to pretty bits of garden scenery, which show plainly that the master hand laid out the grounds, had the knowledge and instinct of a true landscape gardener. Many choice Coniferæ have also been freely and well planted, with the result that to-day many magnificent specimens may be seen at Combe. Noteworthy among them are large and perfectly shaped ones of Picea pinsapo and P. pinsapo glauca. Isolated specimens and lines of Cupressus Lawsoniana are to be seen in abundance. In fact the whole place abounds in vigorous examples of ornamental trees.

The above are a few brief notes about a fine and well managed garden, the conduct of which has been in the hands of Mr. W. Miller for thirty-six years. He went to Combe at a time when it practically possessed no garden, and during his term of service has laid out the whole of the grounds and kitchen gardens, built houses, furnished them with plants, splendid Vines and fruitful trees. A man who does such things as these helps to raise the status of gardeners, adds to the prosperity and progress of horticulture, and is therefore deserving of recognition when honours to horticulturists are again passed round. Fortunately the present Lord and Lady Craven are young, and as they gradually settle down in their Warwickshire home, will perhaps add new features to their fine gardens, especially as they have the right man in the right place to carry them out. In conclusion I beg to tender, on behalf of my companion and myself, our heartiest thanks to Mr. and Mrs. Miller for the kind hospitality extended to us at the time of our visit.—H. D.

DENDROMECON RIGIDUM.—Mr. E. D. Sturtevant writes to the "Garden and Forest" from Los Angeles, California, with reference to this plant, which in California is considered one of the finest native shrubs. The flowers are of the brightest pure yellow colour, about 2 inches across, and produced for a long period. The foliage is a peculiar greyish green, but the flowers are so beautiful that this may well be overlooked. Unfortunately, it is difficult to transplant; but if successfully moved it grows well in gardens there.

FRUITS AND FLOWERS AT LANGLEY.

TRAVELLERS on our great railway systems, who leave the metropolis on pleasure or business bent in their millions, have much for which to thank our nurserymen. These have in many instances established themselves by the railway sides, and thus provide floral and arboricultural treats, the parallels of which are not to be found elsewhere. "They have done it," some may say, "with a view to advertising themselves." True, but it will be acknowledged that only a small per-centage of the travelling public is a purchasing public, and the remaining vast majority see the displays and appreciate them as they pass by. Other firms advertise their cure-alls or wash-alls by immense boards, which, however useful, are by no means ornamental. The beautiful flowers and the shapely shrubs and trees adorn our already charming English landscapes, but the boards do the exact reverse, so that though both have the same object, the one is advantageous, while the other is an eyesore and a nuisance.

The journey that more especially called forth the above remarks was made from Paddington to the West of England in August, when the exceptional beauty of Messrs. J. Veitch & Sons', Ltd., Langley Nursery, caused the determination to pay an early visit to this land of fruit and of flowers. For going on to two decades this nursery can be remembered by the writer, and each year it has been passed at least once at some period or the other. Never, however, has the spectacle been a more glorious one than this. Each bed has been a picture in itself, and the whole has been appreciated by hundreds of thousands of people. There were flowers of all colours and shapes, plants of varying heights and habits, with hundreds, nay, thousands of fruit trees to be seen from the windows of the, for the moment, too rapidly running train. After thus generalising we must particularise for a little in order that Journal readers who have not been on the Great Western this year may see Veitch's by proxy, which, it is hoped, will be better than not seeing it at all.

GOOSEBERRIES AND CURRANTS.

Most visitors to a fruit nursery when penning their description of its contents commence with the Apples and Pears, passing thence to the smaller fruits. In this instance the order will be reversed, so that the notes may claim some atom of originality in their sequence, if in nothing else. At Langley all forms of training Gooseberries are adopted save one. There are cordons, single, double, and five-stemmed, fan and cup-shaped bushes, standards on 9-inch or 12-inch stems, but the old-fashioned stool bush was conspicuous by its absence. Asked why this was the case, our conductor stated that there was no demand for them nowadays. "Growers," he added, "recognised the distinct advantages of plants on straight, clean trunks, and will have no others from us." The thousands so grown are as perfect specimens as anyone need wish to have. As proof of the care taken in removing the eyes from the part below the soil it may be mentioned that in no single instance was a sucker growth observed.

For fruit-bearing properties, perhaps, the shape of tree which may be termed the five-stemmed cordon must have the place of honour for bulk of crop. But for size of individual fruits and quality commend us to the single-stemmed cordon, which appears to be unrivalled. The other forms of training the bushes undoubtedly give splendid returns for the space occupied, and if the cup-shaped ones are a trifle formal they are nevertheless very handsome when roped with fruits. For many positions in gardens they are well adapted, and would look considerably better than an ordinary bush. In one respect the several forms were alike, and that was in the splendid growth and cleanliness. Such wood and foliage would satisfy the most hypercritical of mortals. "What," we hinted, "was the secret of such results?" With promptitude came the reply, "Simply good cultivation." It may be added, parenthetically, that the "good cultivation" included the best stable manure procurable.

From the spiny Gooseberries (there were no spineless ones to be seen) an adjournment was made to the Red and White Currants. Again were found some half-dozen forms of training, rendering it a most easy matter to choose a shape for any conceivable position where a Currant will grow. Haunters of the London Scottish Drill Hall on show days will remember these with the Gooseberries that the firm has staged so splendidly from its Buckinghamshire emporium. The attention devoted to the Reds and Whites is equalled by that given to the Blacks, but the training of the latter is, as may be imagined, much more simple. No writer would have the temerity to commence naming the varieties of the two fruits that have been mentioned. Let it suffice to say that probably every known variety is there to be found, though not in equal numbers. Of one there will be thousands, and possibly of others dozens would easily cover the stock that is grown. Both Gooseberries and Currants have cropped splendidly in these nurseries this year.

STRAWBERRIES.

These, the pigmies, so far as height is concerned, of the fruit world must not be omitted, or the opportunity of referring in laudatory terms to the grand Veitch's Perfection would be lost. If anyone present on a certain occasion at the Drill Hall had a lingering doubt as to the quality of this variety being of the best, it must have been rudely dispelled when he saw the avidity with which the best of judges disposed of several pounds of fruits that had been sent for testing. The writer knew the lusciousness of it, and though it is one of his principles to be "in" on such an occasion, he was hopelessly "out" on this one, and, moreover, has never ceased to regret it. It must rank with the very best, and does so with those who have grown it, for in addition to

the desirable attribute, it is a splendid cropper and of excellent constitution. The plants of this and many others are in the best of condition, and give abundant promise of producing heavy crops next season. In the performanee of their duty, too, it is perhaps superfluous to say the many thousands will be expected to produee several thousands more, and one may feel safe in saying that they will do so.

Plums and Cherries.

It is a novelty to go to Langley in September and not be able to find a few Plums with which to refresh the thirsty scribbler. But this was exactly the state of affairs on this oeeasion, for almost without exception the whole of the fruits were knocked off by the Jubilee hailstorm. The trees of these two delicious stone fruits were in excellent condition, and the standards here, with the trained trees yonder, were models of what trees ought to be. Straight and clean was the growth on all of them, and it is probable that next season the trees whieh are fruited yearly will render a good aecount of themselves, and thus make up for the defieieney of this. The foliage was perfectly clean, as visitations from inseet pests are always being sought for, so that if one appear it must pay promptly by death for its rashness; thus they never get a firm hold, and as a consequenee give eomparatively little trouble, whereas when once they become established it is no easy matter to dislodge them.

Apples and Pears.

These, in combination, oecupy a very large area, and whichever way one turns one is eonfronted by Apples or Pears in some shape or another. They may be bushes, espaliers, pyramids, standards, or some other shape, but there they are in thousands. Miniature bush trees scarcely 4 feet in height produee handsome fruits, espeeially of some varieties, others not apparently taking kindly to this system of culture. This is the style of tree which is rapidly beeoming more and more popular, for it eommences to bear fruit in a very small state, and continues with comparatively little trouble in respeet of pruning over a very considerable time. Another advantage that weighs in its favour is the fact that it does not take up very much ground space. For affording fruits, however, over the very longest period, of course we have the standard either of Pear or Apple, but it is some time before these are bearing profitably. Then, too, they, by their great spread of branches, are unsuitable for cultures of limited area where it is desirable to get heavy crops of vegetables from the ground. Cropping can be donc beneath the trees, but the results are never entirely satisfactory, for obvious reasons.

The Langley standards, however, are amongst the best of their kind. The stems are clean and straight, with no wounds or blemishes on them, while the summits are crowned by a beautifully formed head. The most careful attention is devoted to the perfecting of all essential points, both in the formation of these and other shapes of trees, for the firm aets up to the old adage, which says, "If a thing is worth doing at all it is worth doing well." But good top growth is of comparatively little use unless there be a eorrespondingly good root growth to balance and support it. This is always kept in view, and every tree to be seen, whether large or small, may be expected to lift with numbers of those fibrous feeders which delight the heart of the fruit tree planter. Splendidly is the ground worked for all, and those that are, so to speak, getting on in years are moved annually, so as to insure the roots being close at home, and make the final transplantation as certain as anything can be. The crops of Apples and Pears have this season been light, but the trees have been benefited thereby, as may be readily seen in the fine wood that has been produced.

Trained Trees.

Beneath this simple heading we would include, as well as the fruits already named, Peaches, Nectarines, Apricots, and Cherries. All these are cultivated in the form of either espaliers, gridiron, candelabra, fan, or other shape, and both at Langley and at the firm's Fulham nurseries at Southfields they are magnifieent. The greatest care is exercised in the selection of the wood, and when that is chosen the training is done on the best possible lines. There is no "sweating" in the labour. The operator has to do his work well, no matter how long it takes, and if he is not equal to it then he is put on to other work that he is able to do properly. That the trees produce fruits might be proved to demonstration by making periodical visits during the season of bearing to both the nurseries named. No gross, sappy, over-luxuriant growths are utilised, but only those that will give the best results in all respects.

Amongst the Flowers.

Floriculture, as has been said, is a feature at Langley, and the collections of hardy flowers, including annuals, biennials, with shrubby and herbaceous perennials, are magnificent. The beds seen from the railway by no means represent the whole of the area under flower culture, for on the other side of the canal, with which the ground is divided, there are scores of beds equally well stocked and exceedingly beautiful. Then there is an admirably managed trial ground where the stocks of seeds are tested, so that the result produced by any seeds from Chelsea may be seen under identical conditions. To give individual reference to all the kinds grown in the beds would be a serious undertaking, and would involve the utilisation of several columns of the *Journal of Horticulture*, so with one single exception no specific mention will be made. Scores can be recognised from the train, and the beauty of the whole will be admitted by everyone.

Michaelmas Daisies.

Taking two things into consideration—namely, the growing popularity of these plants and the completeness of the Veitchian collection, it will be permissible to give these a special paragraph. There have flowered this season seventy-two varieties, but many of these not being worthy of specific names the number is being very largely reduced. Only those of deeided merit are to be retained, and it cannot be doubted that the deeision is a wise one from all points of view. Large numbers were flowering when this visit was paid, and the names here given may be aceepted as being some of the best, both as regards habit and floriferousness. Half a seore only were ehosen, and comprised acris, amellus bessarabieus, candida, longifolius formosus, F. W. Burbidge, Herveyi, Riehard Parker, densus, eordifolius, and formosissimus. Others equal these no doubt, but few or none are better.—Visitor.

IRIS BAKERIANA.

There are some growers of alpine flowers who do not care to admit flowers of bulbous habit to their roek gardens. It is gratifying to see that this feeling is not generally found, and is rapidly giving way to a keen appreeiation of the beauty of the flowers yielded by what are known, unscienti cally but broadly, as "bulbs." Among the host of desirable flowers belonging to these the dwarfer Irises yield to none in beauty, and these, again, give few more suitable speeies than the one under notice. I. Bakeriana is, in a word, a gem of the first water, and not unworthy of the great botanist who, among other things of highest value, has given us a most useful and convenient handbook of the genus to which it belongs.

I. Bakeriana is a native of Armenia, and is quite hardy in our climate, although it flowers so early that its blooms have sometimes to be proteeted from the inelemeney of the weather. It usually blooms before Iris reticulata and its varieties, and in the South opens early in February. The flowers have sky-blue standards, and the falls, which have the ground eolour white, are beautifully blotehed and spotted with dark violet-blue. It only grows about 6 inches high, and no more appropriate plaee can exist for it than a sunny nook among the ehoieer alpine flowers.

Those who wish to possess this eharming Iris should proeure it as early as possible and plant it about 3 inches deep in sandy peat or other light soil. In gardens subjeet to wireworm it will be found advisable to place a few pieces of Potato just under the surface of the soil near the plaee in which the eorm or bulb is planted, and to examine these occasionally, destroying any wireworms which may be seen.—Alpinus.

THE YOUNG GARDENERS' DOMAIN.

Figs under Glass.

Among dessert fruits found on our English tables a dish of well-grown Figs deservedly takes a prominent position, also on the exhibition table it carries great weight. I purpose now to give a short artiele on their cultivation. The first point to observe is thorough eleanliness, and as most of the leaves will have fallen when this appears in print, the time will be opportune to eommenee a thorough cleaning of the trees and their surroundings, the former by eareful scrubbing with a soft brush, using a strong solution of Gishurst compound, warm (insecticides are always more effective when used warm), and the structure by scrubbing well with soft-soap and petroleum dissolved in hot water.

Previous to cleansing, however, the trees will require to be pruned. Shoots of medium strength of the current season's growth should be left full length in sufficient number to be distributed over the trellis at an average distance of say 9 inches apart; this will allow of next year's bearing wood being laid in between them. I am speaking now of trees trained close to the glass in the same manner as Peach trees; therefore, if this last rule be observed, the trees will require to be shaded with a double thickness of herring nets, as partial shade is very necessary to the well-doing of Figs.

It has been proved that the most satisfactory results have been obtained from trees having a restricted root area (ours are growing in large boxes about 5 feet square). The best compost is a porous one with ample drainage below, such as a good turfy loam with a liberal admixture of lime rubble and $\frac{1}{4}$-inch bones pressed down firmly.

Provided everything is in readiness a start may be made to force the earliest house at Christmas, from which ripe fruits may be expected at the end of April. If at all dry give the roots a thorough watering with clear water, afterwards liquid manure. Figs should never be allowed to become dry at the roots; this, in my opinion, being one of the ehief causes of the first fruits falling off prematurely. It must be remembered that no sooner has a tree yielded one crop of fruit than its energies are being directed towards the formation of the next crop; therefore if the roots become dry, especially during autumn, the embryo fruits will certainly suffer.

A temperature of 50° at night, with a corresponding rise of 5° by day with fire heat and 10° with sun heat, will be sufficient for the first six weeks. Syringe the trees lightly on fine days, admit air cautiously, and close early, to bottle up all sun heat obtainable.—Youngster.

Culture of the Grape Vine.

(*Continued from page* 299.)

After planting, endeavour to obtain good growth by the maintenance of a moist atmosphere, oeeasional syringings to keep the young Vines clean, and careful ventilation. Do not resort to stopping practices, while as the season advances gradually admit more air, and reduce the atmospheric moisture until the canes go to rest. Keep the Vines as cool as possible during winter, the house being thrown open on all favourable occasions.

If the Vines in the first year after planting are intended for early forcing the house must be closed about the middle of January, allowing a

temperature of 40° to 45° by night. On the other hand, if the Grapes are intended for later use, the Vines may be allowed to break naturally without the aid of fire heat. Examine the border, and if dry afford a good supply of tepid water. As the buds begin to push, raise the temperature to 50°, 55° by night. Slightly syringe the canes twice a day, and as growth advanees raise the temperature to 60°, 65° by night. Be very careful in giving air, as a sudden rush will often cripple the tender young growths. Let this be governed by the outside conditions of the weather, admitting very little at first, with a gradual inerease, until the maximum which is thought safe is reaehed. Close the house early, endeavouring to keep a genial atmosphere, and the Vines free from insect pests. Do not stop any of the growths, neither leader nor laterals, as it must be borne in mind the more foliage our young Vines make the more roots we shall have. The laterals should be tied to the wires as growth advances, to avoid a mass, and to allow the sun to get at the wood as mueh as possible. See that the young Vines do not suffer from laek of water, but do not afford too much, or it may make the border sour. As the season advanees gradually harden the growth made, but do not on any aeeount remove any leaves. All the leaves having fallen, rest the Vines, allowing plenty of air day and night.

Some time before starting the house, in the seeond year, which should be one month earlier than in the first, the young canes must be cut off to within 2 feet of the wires, the laterals being pruned to a single eye, dressing the wounds with either knotting or styptic to prevent bleeding. The treatment this year will be very similar to last, only the laterals must be stopped at four or five leaves, and any bunehes whieh show should be pinched off.

The Vines ought now to be thoroughly established. In pruning during the third year, cut the cane to about 8 feet from the wire, and the side shoots to the first good eye. Make all clean by thoroughly washing the glass and woodwork of the house, and afford the Vines a dressing of Gishurst compound, used according to the direetions. Slightly fork the surface of the border, giving a top-dressing of good loam in whieh a little wood ashes and soot are mixed. Close the house about the middle of November with a temperature of 40° to 45°. Give the border a thorough watering with clear water, used at a temperature of 80°. We will now leave our young Vines to break, and endeavour to give the future cultivation in further articles.—SEMPER.

HARDY FRUIT GARDEN.

Lifting Fruit Trees.—Young trees planted in the course of recent years frequently develop a tendeney to grow too vigorously, making wood growth, and showing few signs of forming fruit buds. At first it is desirable to eneourage considerable freedom in the formation of wood, so that the trees may build up a regular and substantial framework of branches. After a certain stage such freedom of growth is undesirable. Should it continue and thus retard the fruiting condition being reaehed, a mild and judieious cheek may advisedly be resorted to. Such a eheek as lifting and replanting will probably accomplish the object sought for.

The present month is a suitable season to carry out the operation, ehoosing the smaller and more portable of the trees or bushes whieh require checking. Large and unwieldly examples are not suitable for this form of treatment owing to their size rendering them awkward to move about. Another objeetion is the larger extent of young wood and foliage present, whieh complete lifting of the roots might cause to suffer. As a eheek to such trees, root-pruning is the proper method.

Lifting and replanting young trees at the proper time may render root-pruning in subsequent years unneeessary, as in the former operation it is possible to carefully cut baek any strong deseending roots and regulate the rest in a spreading, horizontal direction. Lifting trees is adopted, not only as a cheek to exuberant growth, but to bring the roots nearer the surfaee where they have the benefit of pulverised and aërated soil, and are more easily fed and watered. The operation requires to be carried out quiekly. Fresh soil for plaeing among the roots should be at hand, and the roots, especially the delicate fibres, ought not to be exposed longer than neeessary to the drying influenees of air. In adding soil, either under or among the roots, compress it firmly. Cut smoothly all damaged or bruised ends of roots, spreading them out in a horizontal direetion to their full extent. Stake eaeh tree firmly, and mulch over the roots with short littery manure.

Root-pruning Fruit Trees.—The fruitfulness of most hardy fruits largely depends on the character of the roots. Strong roots strike deeply, and, becoming stronger from the excess of moisture available, cause the stems and branches to increase in size more rapidly than is desirable. A rieh, loose, deep root-run favonrs the descent of roots into the subsoil. A firm, but fairly rich rooting medium induces roots to spread more and partake of a fibrous character, while the wood produced is of medium strength, having a tendency to form both wood and fruit buds in due proportion.

Trees Requiring Root-pruning.—An unfruitful condition from over-luxurianee is the principal indication that the roots should be checked. Root-pruning must be carried out with judgment, and only with trees that can produce their fibrous roots near the stem, and not at a distance away, as in the case of trees grafted on wildling stocks. Apples on the Paradise stoek, Cherries on the Mahaleb, and Pears on the Quince have the habit of producing their best roots near the stems, and continue to do so under favourable conditions of soil and position. Unsuitable treatment and other causes may encourage roots to extend beyond a desirable radius or to descend deeper than is beneficial.

Effects of Root-pruning.—When carried out judiciously and not too severely it affords a check, limiting the produetion of strong sappy wood, and concentrating the energy of the trees in the more liberal formation of fruit buds.

Approved Methods.—The method of carrying out root-pruning consists in first cutting a trench round trees 3 or 4 feet away from stems, severing all the roots found to a fair depth. Roots of slender size and fibrous may be preserved intact if possible. When the trench has been excavated to a sufficient depth, undermine the ball of roots. Cut off the strong, perpendicular roots with a clean transverse eut as a finish. The thick roots entering the trench from the side of ball must be carefully pruned with a cut slanting upward. No roots should be left without smoothly pruning the ends, or the principal object of root-pruning—the emission and multiplication of fibrous roots—will be frustrated. Roots left in their damaged state by the rough severanee of the spade cannot properly heal and send forth new rootlets, but instead they die back.

When root-pruning must necessarily be severe to effeet an improvement only treat half the roots at a time, leaving the remaining half for the next season.

In filling in the soil again round the roots add a little fresh compost to the old material and compress the whole firmly. A mulch of littery manure spread on the surfaee over the roots will be of service.

FRUIT FORCING.

Cucumbers.—The autumn fruiters being in full bearing must not be overcropped, but the plants will bear enormously if well supplied with nourishment. Cut the fruit directly it becomes fit for use, also remove tendrils, male blossoms, and an excess of fruit blossoms or deformed fruits. Supply a little fresh loam to the surface of the beds as often as the roots appear, and let it be warmed through before using. Examine the plants at least once a week for the removal of bad leaves, and for stopping and cutting away the superfluous growths. Sweetened horse droppings sprinkled on the beds occasionally act as a gentle excitant to the roots, supply nourishment to the soil, and ammonia to the atmosphere. Spare no effort to keep the foliage clean and healthy, and do not permit accumulations of dirt on the glass.

Allow the winter fruiters to extend well up the trellis before stopping them; train the shoots right and left at about 1 foot distance apart, crowding being fatal to well-developed foliage, and the sturdier the plants are grown the better will they be able to withstand the trying ordeal of continued dull or prolonged severe weather. Earth the roots as they protrude from the hillocks or ridges, supply water as required, not less in temperature than that of the bed, being careful not to overwater, or allow the plants to laek needful supplies of that element and liquid manure, or surfaee dressings of fertilisers washed in. Maintain a night temperature of 65° to 70 in mild weather, 60° to 65° when the nights are cold, 70 to 75° by day artificially, advancing to 80°, 85°, or 90° with sun heat. Admit a little air at the top of the house whenever the weather is favourable, but avoid cold currents; indeed it must be done without lowering the temperature or drying the air too much, and lose no opportunity of closing early in the afternoon on days when a little ventilation has been given in the early part of the day. On dull days little moisture will be required, but on very fine days the plants may be lightly dewed, and the floors and walls damped in the morning and afternoon, also when much fire heat is used in the evening.

Figs.—*Early Forced Trees in Pots.*—Trees that are to be started gently about the middle of November to afford a supply of ripe fruit at the close of April or early in May, will now need to have the wood brushed over, using petroleum softsoap, 4 ozs. to a gallon of water, applying the solution with a brush at a temperature of 120° to 140°, and reaching every part, being careful not to rub off the embryonic Figs, or to injure the shoots, as those of the current year are very brittle. If trees have to be purchased, select those with single stems, and such as have not been hard second cropped, thoroughly ripe in the wood, and having Fig buds in evidence of cropping. The large fruits will not come to anything, it is the small rounded fruit or buds that give the first crop. The trees may be potted if they require a shift, but let it be small; in fact it is wisest to merely cut off the drainage portion of the ball, loosen the soil at the sides, and remove the loose surface soil, shortening any straggling roots, and return to the same size of pot, or such as will admit of a little fresh soil under, around, and over the ball, all pressed as firmly as possible. Figs like a calcareous soil, say three parts yellow fibrous loam, one part old mortar rubbish, one part road scrapings, and one part stable manure, with a 9-inch potful of quarter-inch bones to 3 bushels of the compost, and a similar proportion of charcoal, all well mixed. Suitable varieties for early forcing are St. John's, Early Violet, Pingo de Mel, and Brown Turkey.

Early Forced Planted-out Trees.—Those planted in borders and intended to afford ripe fruit at the end of May or early in June, they being started at the new year, must now be untied from the trellis and pruned. Trees restricted at the roots to firm small borders will, from their short-jointed and sturdy growths, require little more in the shape of pruning than thinning-out the shoots where too crowded, and cutting away the

parts which have reached the extremities of the trellis, and become bare of fruitful wood. Those not having the roots restricted will require hard pruning at the upper part of the trellis, allowing room for the growth of the successional branches; but severe pruning only induces stronger and less fruitful growths. Such trees should be lifted, and have the roots confined to narrower well-drained borders of firm soil. Remove the surface soil down to the roots, pick out the old soil from amongst them carefully, and supply a top-dressing of fresh loam, with some old mortar rubbish added and intermixed. Ventilate fully at all times, except when frost prevails, and at such times heat should only be used to exclude it, though the trees will not take any harm unless the weather is very severe.

Succession Houses.—When the leaves have fallen prune the trees and well wash them with a soapy solution, using a brush, which will do much to dislodge the insects, and after the woodwork and walls have been scalded with hot water, keeping it off the trees, the latter may be dressed with an insecticide and the walls limewashed. Complete any root-pruning, lifting and laying the roots in fresh compost. Fig trees with the roots restricted are more manageable and fruitful than those with an unlimited rooting area, therefore lift and root-prune any unfruitful trees, and restrict the roots to moderate sized borders, making the soil firm, and employing good loam with a sixth of old mortar rubbish and a similar amount of road scrapings, good drainage being afforded.

Late House.—The trees should have the wood cut out that has borne fruit and is no longer required, and any trees having a tendency to cast their fruit through over-luxuriance should be lifted and have the borders lessened so as to restrict the roots. When the leaves fall the trees must be unloosened from the trellis, and being tied together they should be made safe against frost by placing a little hay or straw amongst them and covering them with the latter or mats, for trees in cool houses suffer nearly as much from frost as those against walls outdoors. The roots near the collar are better with a slight protection of dry material.

Peaches and Nectarines.—*Early Forced Trees.*—Where the supply of fruit in late April or early in May is from trees of Stirling Castle and Royal George Peaches, Lord Napier and Stanwick Elruge Nectarines, forcing must commence in earnest at the beginning of December. The trees, therefore, must be got into proper order without further delay, not, however, putting on the roof-lights to make things comfortable, as they are better off until the time stated, and there are favourable opportunities for attending to the necessary work, though it is better done as soon as the trees become leafless.

Succession Houses.—When the leaves are all down, there not being any forcible means taken to secure that end until they part freely from the trees, unfasten the trees from the trellis, and prune them, also thoroughly cleanse the house, washing the trees with soapy water and following with an insecticide, secure them to the trellis, leaving room for the branches to swell, as tight tying is one of the most prolific sources of gumming. Clear away the loose surface soil or mulching, pick some of the old soil from amongst the roots and supply fresh rather strong loam. If the roof-lights are not moveable, give a thorough supply of water to the inside borders, and do not allow them to become dry during the resting season, ventilating fully. It is better, however, to remove the roof-lights, and let the rain cleanse and refresh the trees, also moisten and enrich the soil through to the drainage. Attend to any lifting, or the introduction of fresh trees, as this work and root-pruning should be performed before the leaves have dropped, yet the wood ripe and the buds plumped. Trees for planting in houses are best two or three years trained to walls, and, lifted in the preceding year, they transplant with an abundance of fibres, and can be forced very well the first year if not started until January, not brought on too rapidly, and not overcropped. Trees, however, that have been grown under glass have the wood better ripened, and are more suitable for early forcing. If young trees must be planted, select such as have no trace of gum, but are clean in growth, not very strong in the wood, shapely, not over-furnished with branches. The sooner they are planted after they are in a fit condition the better.

Late Houses.—Cut away the non-extension wood that has borne fruit, as well as other growths not required, as this lets daylight reach those that are left, and nothing is so prejudicial as too much wood in late houses. Any trees in an unsatisfactory condition should be lifted as soon as the leaves commence falling, laying the roots in fresh, firm, sound material.

PLANT HOUSES.

Allamandas.—These will continue to flower for some weeks longer, provided they are liberally supplied with stimulants. Plants grown in pots will be crowded with roots, and a dressing of decayed manure on the surface will help them to develop their flowers; in addition to liquid manure frequently, artificials may be applied to the surface. If the plants are not well supplied with food the flowers will be small and only poorly developed. Growths that have done flowering should be thinned out, so that the energy of the plants may be devoted to the development of the flower buds that are formed. Light will also be admitted to the occupants beneath and also to the flowers, which will be of a brighter colour.

Gesneras.—Be careful not to water these on their foliage or they will be browned and disfigured. At this period of the year until they come into flower they do best on a shelf fairly close to the glass, where a good heat and a fair amount of moisture is maintained. Give these plants clear soot water every time they need water. Be careful not to allow them to become dry; on the other hand they should not be kept wet.

Tydæas.—Those that are coming into flower may be removed to the stove proper, but they should have the driest position or the foliage will damp. The remaining portion of the stock may be given the treatment advised for Gesneras. Spring-flowering kinds of the Madame Heine type that do not make underground stems may have a temperature of about 50°. These do best standing on some moisture-holding material.

Crotons.—Plants that are needed for room decoration should be given slightly cooler treatment than the main stock of Crotons. When well hardened these plants last in such positions for a very much longer period of time; in fact, double the length of time than when removed from a close moist structure where a high temperature is maintained. Growth should now be complete, and no attempt must be made to force these plants to grow. Young leaves made at this season rarely colour, and if used in rooms before these are developed they invariably flag and frequently fall off.

Acalyphas.—Plants grown for winter decoration in rooms should not be kept too warm, or they will continue to grow and the young leaves flag when removed to cooler and more draughty quarters. These plants should occupy an intermediate structure where air can be given daily. This not only prevents further growth but hardens the plants so that they bear room decoration fairly well for a time without losing their foliage. For the conservatory in summer these plants will in future replace Coleus altogether. When properly grown for this purpose they stand well and are much more effective, being choicer in appearance than Coleus. Plants that have become shabby may be cut down and placed in heat to break. Keep them on the dry side at first or the roots will perish.

Poinsettias.—The earliest plants will have commenced to show their bracts, and these may have a temperature of 65°. The plants, if strong and well grown, will develop large bracts in this temperature. Keep them as near the glass as possible; on this depends whether the bracts are brilliant in colour or the reverse. Feed with weak stimulants every time water is needed. Later plants should be kept at 60° with a little air daily until growth is completed, when the temperature may be raised. If kept too warm before the completion of growth the plants often start growing, and only poor bracts are produced.

Euphorbia jacquiniæflora.—Keep plants at 55° to 60° until they display their flower buds; if the growths have not been well ripened and are kept too warm they will start into growth instead of flowering. Once they do this all chance of their blooming satisfactorily is over. Do not overwater these plants, for they are very liable to go off at their roots if kept too wet. Justicia flavicoma, not yet showing flower, may have the same treatment. Plants that are showing flower may be brought into bloom in the temperature advised.

Celosias.—Plants that have been kept in a temperature of 55° to 60° to bring them into flower should be carefully and gradually hardened before they are placed in the conservatory. When forced in heat and removed direct to a lower temperature they are liable to damp off just above the soil. When care is taken to harden them they should be watered judiciously, and then they will last a long time.

THE BEE-KEEPER.

NOTES FROM THE HEATHER.

IN this county of broad acres there is a wide expanse of Heather, and within thirty miles of my apiary there are thousands of acres that in the season form a mass of bloom, a very small percentage of which is visited by the bees. Although bee-keeping has advanced by leaps and bounds during the past quarter of a century, it is an acknowledged fact that less honey is now obtained from the Heather than was formerly the case. As the honey obtained from this source is often preferred to any other, it would appear at first sight as if apiculture was declining in this country; but that such is not the case we have ample proof. What, then, is the reason that so few bee-keepers now send their bees to the moors so as to obtain a surplus from the Heather?

It is owing to the unfavourable weather usually experienced when the Heather is in bloom and the honey flow at its height. The past season has not been an exception, as from our own observations and reports to hand from bee-keepers who, after great expense and labour in taking their bees to the moors, pronounce the yield as nil. This is the more disappointing after the bright weather experienced in July and early in August. Owing to the excessive heat the Heather was a few days earlier than usual in coming into bloom. Under these favourable conditions more bees than usual were sent, with the result as stated above. This was caused by a rapid change; high winds and a low temperature prevailed, the much-needed rain for all vegetation throughout the country came down in torrents, and with it the bee-keeper's hopes fell to zero.

The unfavourable weather, from a bee-keeper's point of view, continued until the early days of September, when there was a sudden change to bright sunshine again. Too late, however, for the bees to derive any benefit from the Heather. Such being the case, nothing remained but to bring the bees home again, and as the hoped-for profits from the Heather had all evaporated, the bees in most instances

had to be fed with syrup, and that freely, to help them to tide over the winter. Only in a few favoured spots has there been a surplus stored this season from the Heather. No wonder, then, that some bee-keepers are found who vow they will not take their bees to the Heather again. But as there have been some good yields in the past, so there doubtless will be again in the future.

Autumn Flowers.

Gardens are still gay with autumn flowers, many of which are of some benefit to the bees, and as the weather continues fine, with a fair amount of bright sunshine nearly every day, the bees are not slow to take advantage of it, and may be seen during the middle of the day returning home heavily laden with pollen. But from what source is it chiefly obtained at this season? Ivy, which has been in bloom for the past few weeks, and which yields a large amount of pollen, is the last tree to bloom in the autumn that is of benefit to the bees. In the neighbourhood of my apiary there are numerous old trees and walls that are covered with huge masses of this creeper, which are never pruned or otherwise interfered with, consequently they bloom profusely. At the present moment, whilst the sun is shining brightly, those trees that are situated in a sunny spot are alive with bees and wasps, whose merry hum may be heard before they are seen, reminding one of the Lime trees when in full bloom in July.

Mignonette is also much frequented by bees at all seasons. The early plants seeded rapidly owing to the dry weather, but at the present time large masses of Mignonette are simply perfection and much appreciated by the bees. Anemone japonica, and the Autumn Crocus, which grows wild in this district, are also useful for bees, and are much admired when grown in the garden.

Winter Passages.

Are winter passages necessary for the well-being of the bees? I answer in the negative. A few years ago they were recommended by many bee-keepers, and still are by some, but after experimenting with several colonies I came to the conclusion there was no benefit to be derived from them. Winter passages are simply holes cut in each comb so that the bees may pass from one to the other to obtain food in cold weather without having to pass round the ends or the bottoms of the frames, where they would be liable to become chilled. Bees, when left to themselves, often make provision for this by forming pop holes in several of the frames, which anyone may observe by examining the combs in a hive. If passages are really necessary it is better to lay a few laths on the top of the frames, as this will allow the bees to go from one comb to the other without any danger of becoming chilled. An extra covering must be placed on the top so as to make all secure.—An English Bee-keeper.

TO CORRESPONDENTS

*** All correspondence relating to editorial matters should, until further notice, be directed to "The Editor," **8, Rose Hill Road, Wandsworth, London, S.W.**, and **NOT** to Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Books (*F. W. P.*).—The translation of the majority of Latin horticultural expressions will be found at the end of the latest edition of "Johnson's Gardeners' Dictionary." If you have not this work you should purchase it, for it contains much valuable information. It may be procured from the *Journal of Horticulture* office, 171, Fleet Street, E.C. "Fruit Culture Under Glass," by D. Thomson, would probably suit you. It is published by Messrs. W. Blackwood & Sons, London and Edinburgh at less than half the price you state.

Diseased Chrysanthemum Leaves (*J. O. M.*).—The leaves are badly infested by Chrysanthemum leaf-rust fungus (Trichobasis or Uredo Artemisiæ, or an evolved form of it), which is described on page 381.

Training Peach Trees (*Mrs. M.*).—The main points to keep in mind are two. 1, To have the lower branches so far as may be practicable longer than those above them. 2, To dispose the branches evenly over the surface, and at distances so that the leaves of one branch do not overlap those of the other. If there are sufficient branches for this there need be no shortening; if too many, thin some of them out. One may be cut back here and there where there is much more space to be occupied than there are branches for covering it. Rank robber growths should not be allowed to form, but rubbed out or suppressed in the summer. Their character is apparent when quite young. Any of an excessively gross nature may be removed, and others not allowed to extend next year. The more uniform the strength of the branches the better, and these should be uniformly disposed with a foot of wall space between them, and even then many of the pushing young shoots will have to be taken out when they are an inch or less in length in the spring, or the trees will soon be much too crowded to be productive. If the lower branches are too weak training them as much above the horizontal position as can be easily done will have a tendency to strengthen them, while depressing those which are too strong will have a contrary effect, and by these methods something can be done towards effecting an even balance in the growths of a tree.

Iceland Poppies (*N. H. B.*).—The white, yellow, and terra-cotta forms of Iceland Poppies (Papaver nudicaule) all come true from seed, and are very easily grown. Autumn-raised plants would flower strongly next summer, but quite as good results attend the practice of sowing early in the year. The seedlings transplant badly, and we advise you, therefore, to sow the seed in small or 2½-inch pots, and transplant direct from these into the open border. Late in February is a good time to sow, and seeing that nearly every seed will germinate sow very thinly, place in gentle heat, and when the seedlings appear raise the pots well up to the glass. Directly the plants can be handled thin them out to about three or four in each pot, and still keep them near the glass. By the time the plants are beginning to spread over the sides of the pots they ought to be sufficiently hardened to admit of their being planted out where they are to flower. Very warm borders do not suit them, nor do they thrive well in an over-damp site. If located in mixed borders, notably those fringing garden walks, with fruit trees dotted along them, the time will soon come when abundance of self-sown seedlings will be always forthcoming. These Iceland Poppies will, as before stated, flower well during the same season they are planted, but bloom earlier and more profusely the second year, after which they are not nearly so serviceable. It will thus be seen that they can be treated either as annuals, biennials, or perennials, and are perhaps the most admired of all Poppies.

Pruning Young Fruit Trees (*Mrs. M.*).—Assuming that the trees were properly planted—namely, the ground broken up to a depth of at least 18 inches, and to a distance of 2 feet from the stems, the roots spread out with the soil between the layers, the uppermost not covered more than 4 inches deep, and the stems not sunk deeper than they were before the trees were taken up, free healthy growth may be expected next year, if the young branches are shortened more than half their length towards the end of the present month. Had they been cut back in July the young growths resulting would not have had time to mature, and the action of severe frost on them might have been followed by canker. Summer pruning does not consist in cutting back all the main branches of young trees, but in shortening side growths from the mains for preventing the great evil of overcrowding. With the same object it is often desirable to cut some of the main branches entirely out, if these are too numerous, or so cross each other as to make the interior of the tree resemble a thicket. This may be done in summer or now. The main branches of fruit trees should be far enough asunder for the sun to shine between them when the trees are in full leaf. For the purpose of obtaining a sufficient number of branches for forming a head for bearing, the few shoots of young trees are cut back, two growths usually resulting from each cut, so that a three-branched tree soon becomes six-branched, or six branches are increased to twelve—a generally sufficient number for bearing; and, as a rule, the less these are shortened the better; but it is most important that they be far enough apart, or the summer growths shortened to prevent the leaves of one branch meeting those of its neighbours. The main branches of bearing trees should be nearer 2 feet asunder than 18 inches. The peeling of the bark off the young branches of your trees that were not cut back after planting, leaving something like wounds, is due to the inability of the scanty leafage to manufacture sufficient organised matter for deposition and the healthy thickening of the stems. If a good free root run is provided for the trees they will make very different growth and leaves another year if the branches are well shortened this autumn, and in all probability the wounds will gradually heal over; but we should cut below the worst of them where practicable. As to "keeping the height of the trees down" permanently, this can only be done at the sacrifice of fruit; in fact, if all the branches made in summer after the heads of the trees are formed be cut back to near their base in winter you will never have crops of fruit worthy of the name. If the standard trees will be too tall for their positions, the better plan will be to plant them elsewhere at the end of this month, and procure dwarf trees of compact growing varieties for taking their places if you wish the site to be occupied with Apples, Pears, and Plums.

EDITORIAL NOTICE.—It is particularly desired that all communications, parcels, catalogues, and newspapers intended for the Editor, be sent direct to 8, Rose Hill Road, Wandsworth, S.W.

Late Pears and Gooseberries (*Inquirer*).—The letter is mislaid, but this reply will be recognised. Good Pears for following Doyenné du Comice are Marie Benoist and Nouvelle Fulvie, large; Josephine de Malines and Ollivier de Serres, medium sized and later. If, as we gather, you intend raising your own cordon Gooseberries, choose upright growers, and take particular care to cut clean out every bud from the part of each cutting that is to be inserted in the soil, also from the part that will be a few inches above it. It would no doubt be better to purchase well rooted plants. A foot apart is a good distance for planting, and they may be trained vertically. If the wall is low the cordons, when they reach the top, can be depressed if you like. It does not matter in which direction. If you slant them at first you will check their extension and force the issue of side growth unduly.

Lycium europæum (*G. C. P.*).—This shrub is a native of the South of Europe, but appears to have become naturalised in some parts of this country. Loudon in his "Encyclopædia of Trees and Shrubs" describes it as "valuable for covering naked walls, as it grows with extreme rapidity, and flowers and fruits freely in almost any soil or situation. Established plants in good soil will make shoots 10 or 12 feet in length in one season, and the plant when trained against a house or high wall will reach the height of 30 or 40 feet, as may be seen in some courts in Paris. Trained to a strong iron rod to the height of 20 or 30 feet, and then allowed to spread over an umbrella head, it would make a splendid bower. Its shoots would hang down to the ground and form a complete screen on every side, ornamented from top to bottom with ripe fruit, which is bright scarlet or yellow, and very showy; with unripe fruit, which is of a lurid purple; or with blossoms, which are purple and white.

Mushrooms on Bench (*T. Q.*).—The proper place for a Mushroom bed is under the stage, not on it, along which hot-water pipes run. These would dry the bed too much, cover them as you might. What Mushrooms enjoy is the mild, moist warmth, that is generated by steadily fermenting manure. With a board a foot wide, firmly fixed on the floor flush with the front of the stage, you would have an excellent enclosure for growing Mushrooms. If you collect and prepare manure as advised in *Mushrooms for the Million*, and when it is sweet, warm, and moist, beat it down firmly with a brick; thrust a couple of pointed sticks in it for withdrawing at intervals for testing the heat; insert good spawn at the right time, and three or four days afterwards spread sound, damp, loamy soil, 3 inches thick, on the surface, beating it down to 1 inch or so; cover with rather damp litter to prevent the evaporation of moisture from the bed, Mushrooms may be expected to grow in abundance. In grasping the sticks with the hand you may find the heat rise from day to day, and not until it has ceased rising and commenced falling must the spawn be inserted. A thermometer closely inserted 3 inches in the bed will indicate the warmth. When this falls below 90°, after it has risen above that point, the spawning may be safely done, but never with a rising thermometer. If by regulating the coverings you can maintain a temperature of about 70° in the bed for three weeks, good spawn will be sure to spread, provided the manure is in the right condition, by the retention of moisture, and Mushrooms will then be bound to follow in due time. One of the chief factors in success is found in keeping the beds uniformly moist without watering them, and this can be done.

Names of Fruits.—*Notice.*—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. *In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing.* The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. *They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state.* (*H. T. M.*).—1, Lord Derby; 2, Reinette Grise; 3, affected with fungus, possibly Cellini; 4, Norfolk Beefing; 5, not recognised; 6. Gravenstein. (*T. M. G.*).—1, Not known, probably local; 2, Warner's King; 3, New Hawthornden; 4, Cox's Orange Pippin; 5, King of the Pippins; 6, possibly an inferior seedling from No. 5. (*H. S.*).—1, Irish Peach; 2, not known, and we should think not worth growing; 3, Court of Wick. 4, Minchull Crab; 5, Winter Greening; 6, Greenup's Pippin. (*P. J. P.*). —The Pears were rotten. The Apple is probably a seedling from Cellini. (*J. B.*).—All the fruits were rotten.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*C. C. U.*).—1, Abelia rupestris; 2, Swainsonia alba; 3, Ceanothus Gloire de Versailles; 4, Escallonia macrantha. (*B. W.*).—1, Aster amellus bessarabicus; 2, A. candidus; 3, unknown; 4, Helenium autumnale striatum. (*E. S. W.*).—Withered; possibly a Japanese Acer. (*A. W.*).—Specimen insufficient; send fertile frond.

AUTUMN MANURING.

At the first glance the question of the application of manure in autumn appears a very simple one. For one thing, very few farmers would dream of putting artificials on in autumn, and the average man would put his muck on lea for Wheat because he found a

convenient interval of leisure before harvest during which he could put the manure on the land. We are not going to argue that farmyard manure is not a good thing for the Wheat crop, but we think it may be used to better advantage than by spreading on the land and ploughing in for Wheat. If there is much herbage to plough in, the addition of a good dressing of muck ploughed in with it tends to make the seed-bed too light, and unless the season be very favourable for the roller, the wireworm has a splendid chance, and may do very serious damage.

We have seen manure put on after the Wheat has come up, and with very successful results. The manure on the surface appears to act as a protection from frost. Of course, it requires to be well spread and shaken out, so that the young Wheat can get its head out.

But with the advance in agricultural science we are becoming more and more convinced that, even with the price at 40s., the Wheat crop is not the one that benefits the most by an immediately previous application of farmyard manure, and would prefer to apply it in autumn, say any time before Christmas, to the young seeds, or, better still, to yearling seeds, if such are to be grazed again; for the pasture will be of so much more value and carry so much more stock, that the following crop, be it Wheat, Oats or Potatoes, will benefit quite as much, nay more, than it would from the direct application of the manure.

Though farmyard manure is more or less beneficial to all soils and all crops, it is not always the best thing to use, and though it contains phosphoric acid and potash it is sometimes necessary, where a soil through natural poverty or overcropping is very deficient in those constituents, to supply them in much larger quantities than would be possible or advisable in the form of muck.

Phosphate of lime can be bought at the cheapest rate in the form of basic slag, the next cheapest being superphosphate of lime; the latter costs about 2s. per unit of phosphate, whereas the basic slag costs only about half that price. The chief practical difference between the two is in the solubility of the phosphate—that is, the solubility in water. The phosphate in the form of basic slag is not readily soluble, and therefore not in a state to immediately benefit plants after application, but when applied to land which is of a sour or acid nature, and deficient in lime and phosphate, it is only a matter of time for the phosphates to become soluble and available as food for plant life.

If we consider, then, the great relative difference in the cost of superphosphate and basic slag, it is obvious that the latter must be the cheaper form to use, but only on one condition, and that is that it is put on the land and harrowed in before the end of the year. Thus there is plenty of time for it to become soluble before the growth of spring requires a supply of readily available phosphatic manure.

What we have said of basic slag may be said with equal force of kainit, which is the cheapest available form of potash, at any rate in an innocuous form. Muriate of potash is relatively as cheap, but the action of muriatic acid is—at least, we have found it so—injurious to plants, though it is in a readily available form. Sulphate of potash is good, but dearer than kainit per potash unit. So kainit seems to be the thing to use, but to reap the greatest benefit it should be applied in autumn. Light soils if heavily cropped are most liable to become poor in potash, and a sure sign of this being the state of things is weakness in the straw of corn crops. Strong soils are seldom deficient in potash, and the straw is generally stiff and bright in colour; but when you see a crop of Barley, about 30 inches in length, laid nearly flat, there must be something wrong, and that something is almost sure to be a shortage in the supply of potash.

Ammoniacal manures should not be put on in autumn unless for Wheat where the land is exceedingly poor, and then only in very small quantities, for double the quantity will be required in spring to keep the crop going.

For a stolen crop of Wheat—that is, one taken out of course, say corn after corn, with no farmyard manure available, we should sow the following mixture—250 lbs. kainit, 300 lbs. basic slag, and 56 lbs. sulphate of ammonia; mix the kainit and sulphate together and sow it, the slag being sown separately; 112 lbs. of nitrate of soda per acre in April will keep the crop growing, and if the land be worth cultivating it should be a good one.

For Barley or Oats miss out the sulphate in autumn, and sow 160 lbs. sulphate of ammonia with the seed in March. No nitrate of soda will then be required. Kainit and slag to be sown in autumn same as for Wheat.

For Turnips, again, we cannot see why slag applied in autumn should not be the best form of phosphate to use, though perhaps a little superphosphate at drilling time might be beneficial.

Professor Long says:—"As between slag and superphosphate, which have been again tested, slag is preferred from the point of view of cost. Nevertheless, it can scarcely be denied that experience teaches the value of mixed manures." Certainly! But a mixture of what? Our mixture for Turnips would be basic slag, applied in autumn with either farmyard manure before sowing, or a mixture of kainit 2 cwt. and nitrate of soda 1 cwt. per acre, sown broadcast and harrowed in before drilling the seed. The kainit might be sown in autumn, and better so if the farmer has quite decided to use it.

WORK ON THE HOME FARM.

We are progressing well with Potato lifting, and the continuance of fine weather is a great boon. The roots go together in fine dry condition, and it is so much easier work for the pickers, who are thus enabled to do more work. There is just a doubt as to some kinds being ready to store, as is shown by several ruffled skins, but fine weather is of such importance, and the season is getting so nearly over, that we shall go on; but at the same time take every precaution to prevent the tubers going wrong in the pie. We are leaving them without soil for three days, and then only soiling them three-fourths of the way up the side, so as to leave a wide outlet for the steam or heat to escape.

Some people are lifting Mangold, and they will soon be ready to store. We like ours to get fairly ripe, and then we put them in heaps 12 feet wide, and holding three cartloads to the yard run; they will keep well in such a heap, and take less covering than if the heaps are made smaller. Some people store Mangold roots, tops, and all, but they bulk up more, and take more covering; and the trimmed bulbs keep equally well, if not better—*i.e.*, with the tops cut off—of course we do not touch the roots. Swedes, on the other hand, pied in small heaps may have the tops left on, and need only to be covered with soil. Mid-November will be soon enough to store Swedes.

Mangolds here are a full plant, but are not large, owing to a late start. Still they should be a fair crop, and considering the shortage in the Turnip crop must be extremely valuable. How serviceable they are! If well taken care of they will keep until August, and are most valuable either for pigs or lambs about midsummer; whilst if wanted during winter they are good for any kind of cattle, and especially for ewes during lambing time. Of course they require heavy tillage and well growing, whilst the early seed-time is a little drawback where the land is not already clean; but the heavy crop and good keeping qualities repay the grower over and over again for the extra cost and trouble.

Sheep are doing well on Turnips, but are travelling too rapidly over the ground. This was, however, expected. We see many cattle out still, and they look very shivery at nightfall; they would be better up. Hay and Clover are in demand, and advancing in price.

REMARKS.

10th.—Fair morning, with gleams of sun; overcast afternoon.
11th.—Rain at 5 a.m.; bright sun from sunrise almost all day.
12th.—Bright sunshine almost throughout; cloudy evening.
13th.—Foggy early, a little sun at times; overcast evening, and slight rain at night.
14th.—Generally overcast and drizzly till 10.30 a.m., and a little sun in the middle of the day.
15th.—Sunny morning; overcast afternoon, with spots of rain and showers at midnight.
16th.—Fair early; bright sun all day.

A mild fine week; no frost in air, and very slight on grass.—G. J. SYMONS.

Journal of Horticulture.

THURSDAY, OCTOBER 28, 1897.

THE JOURNAL OF HORTICULTURE *can be obtained from the Office*, 171, *Fleet St., London, post free for a Quarter*, 3/9. **Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.**

HONOURS IN HORTICULTURE.

PRESENTATION OF VICTORIA MEDALS.

WHENEVER honours are accorded, no matter in what form, in clerical, diplomatic, legal, scientific, or any other circles, differences of opinion arise as to their exact appropriateness. This is only to be expected in a world which contains so many persons who may, for all practical purposes, be equally entitled as participants. There are, moreover, always a few excellent men who cannot see the necessity for any honours at all, even though they may have been compelled to be decorated with sundry alphabeticals—well won and worthily borne.

Few honours, beyond the winning of prizes at shows, are provided and distributed in the domain of horticulture; and it may fairly be said that the Victoria Medal of Honour, instituted by the Royal Horticultural Society, in commemoration of the wonderful reign of its Royal patroness, was a great departure from orthodox routine. It undoubtedly was; and even though few, very few, may have dissented from its form, it was, judging by the gathering in Westminster on Tuesday last, and the tone of that great meeting, one of the most popular, if not *the* most popular, "departure" the Royal Horticultural Society has made for a very long time.

Never before has such a crowd assembled in the Hall in St. James Street at a meeting of the Society as on the occasion of the distribution of the medals in question, and this function, with the luncheon preceding, cannot be otherwise regarded than as a distinct success. Not a hitch occurred to mar the harmony of the proceedings, and the hundreds of on-lookers were evidently as happy in their plaudits as were all those of the "sixty" who could attend, as apparently nearly all of them did, to receive the golden symbol in honour of an event so unique that its parallel can scarcely be expected to occur again. The occasion, then, was historic, and the method of celebration was unmistakeably regarded with distinct approval.

As to the recipients of the honour conferred, it may be fully conceded that there are those, and even many, as well entitled to receive it as were at least several of those who were chosen as worthy, in

some way or other, by the Council of the Royal Horticultural Society. We do not say that the equals of all could be found who, in their respective spheres, have rendered signal service in the scientific, practical, or administrative aspects of horticulture; for, to cite no others, there is only one Sir Joseph Hooker, one Dean Hole, or one Baron Schröder, and it may be said that no recipients of the Victoria medal appreciated the distinction conferred on them by its possession more than they did, and none on receiving it at the hands of the President received warmer greetings from the densely packed audience.

The Council of the Society has naturally, from time to time, had many difficult problems to consider and to solve, but it is questionable if, during recent years at any rate, any one of them has given cause for more anxious thought and serious consideration than the weighing of the claims of hundreds of able persons whose names must in the very nature of things have been brought under review. The task of determining the final choice must have been in its way herculean; but as was clearly set forth in the admirable speech of the President at the luncheon, to which the elected Victorianists were invited, the decision did not turn so much on individuals as on groups and their representatives, such as, for instance, the scientific and commercial sections, with amateur patrons of gardening, and actual workers in it. That has clearly been the principle on which the decisions were based.

It cannot be said that gardeners have not had their full share of recognition, and this, no doubt, accounts largely for the general approval with which the decisions have been met, though we thoroughly believe there are no men who value more highly the important work of their scientific coadjutors than do the intelligent working gardeners of Britain. They could not, in fact, have been so accomplished as they are had they not made themselves, as far as they could, acquainted with the researches of men whose patient investigations have done so much in showing the way—the true way—to the achievement of the useful objects in view.

Perhaps if there is one section of horticulturists who, in proportion to the work they have done, and are doing, who are the most sparsely represented, it is that known as growers of garden produce for market—men who, by their remarkable enterprise and cultural skill, have accomplished so much in bringing the wholesome influences of gardening into the homes of the people and brightening their lives. Even this section is not forgotten, and in time the great and good work that is done in the direction indicated will be more fully understood and appreciated. But after all only sixty persons —the number corresponding with the years of her Majesty's reign— could be chosen out of thousands, while none of the members of Council could be elected—a pity, since they have done so much for British horticulture.

The proceedings of the historic event of the 26th inst. are narrated in the report on page 414.

HEALTHY FRUIT TREES.

The articles in the *Journal of Horticulture* on fruit culture have been of much interest. To me it seems that some writers pin their faith to one method too securely, as being the right and only manner in which the production of fruit or successful combatting of tree diseases can be accomplished, and this without inquiring into the predisposing cause of fruitlessness or tendency to disease. Take, for instance, canker. Has not deep-rooting something to answer for, this imparting to the tree a tendency to become susceptible to attacks of diseases? Certain it is that the removal of the roots from unaërated subsoil, that frequently contains quantities of injurious iron, into well aërated soil near the surface, has a powerfully beneficial effect on the tree; and if, in addition, this soil contains the necessary quantities in proper form of the chemicals required for sustaining healthy growth, it will matter little how they are supplied, whether as "ate" or "ide," or as "just manure," only keep the proportions true. This will assist greatly in warding off attacks of disease, or defeating them when existent. Trees, when properly supported, are enabled to maintain a healthful, fruitful condition. The knife will only be needed for regulating the branches.

The secret of successful culture undoubtedly lies in sound, firm, clean healthy trees, and this is most easily secured when the roots are kept near the surface, where they derive the most benefit from, say a judicious application of "just manure," seasoned with "ate and ide." Under most circumstances such a blend will prove beneficial, if properly balanced and applied at the right times.

Much could yet be written by such men as Mr. Abbey (long may he live to write) as to how trees take their food from the soil by means of the root hairs; how it is manufactured in the leaf and stored in the fruit, or otherwise employed in building up the different parts of the tree; what that food consists of; how it is obtained from the film of moisture surrounding the particles of earth, and how or in what form additions to present quantities can best be made; also as to the influences on fertilisers, on the colour and flavour of fruit.—Fifer.

FRUIT AND TABLE DECORATIONS.

In thanking "H. D." for his efforts to remove the wrong impressions he fancies I am labouring under, I should like to know if there is any mistake where he says that at one time the young men used to turn out *en masse* to prune and nail wall trees. I have always regarded pruning as an important part in the cultivation of fruit, and one which some experience was necessary to carry out successfully. Has "H. D." given us the index to the decadence in wall fruit culture? I shall be surprised to hear that young men were permitted to use the knife on the well-trained and fruitful examples referred to by himself and his friend "Melton" unless under the watchful eye of the chief.

I am still under the impression that plant and floral decorations are not the cause of the many bad instances of cultivation we see, or that they can be held responsible for the deprivation of the assistance at one time given by the young men in nailing and pruning. What our fruit trees on walls and in the open are suffering from is the want of men who have both the knowledge and inclination to show their men how to work. There are still many places where work is not so pressing at this period of the year, but that the men might be directed how to improve unsatisfactory trees which ought to be made to pay for the labour of attending to them, or make room for others that will.

Those who cannot look after the trees and fruit themselves, should place them in the hands of an intelligent labourer. Give him a respectable wage, with a comfortable house and garden. Satisfy yourself that he is the man for the place, and fix him to it. Teach him to snatch the superfluous shoots off in summer, to shorten back spurs, not only on wall trees but those in the open, to discriminate between branches that are healthy and those that are brown half through. Such a man will be found invaluable also in the gathering and storing of fruit. Most gardeners know how difficult it is to impress on old and young men the necessity of careful handling. I do not intend to convey that such a man would have fruit trees as his primary object, he would be equally useful in other departments.

We have our share of decorative work, and know the value of 200 or so of Chrysanthemum plants for cutting from to carry us on until the end of January, in addition to those grown for exhibition. There are, also, 300 or 400 Cyclamens in 5, 6, and 7-inch pots; 100 or so of Arums in 8, 9, and 10-inch pots kept in them through the summer, specimen Azaleas and other plants now so generally employed in decorating, to be attended to. Yet the young men (and this is the point) have been able to help with fruit gathering (not a small matter with us for a private establishment this year) the watering of trees against walls and those in the open; also Celery (our water is applied with buckets), and the men are now ready to give a little assistance with nailing, lifting, or planting, or any other work where it is advantageous to concentrate labour. Are we more favourably situated than others generally? I shall have no difficulty in showing that we are not.

With respect to table decorations it seems I have been misled. My employer, in whose taste and knowledge I have the greatest confidence, orders the fruit to be placed on the table. I am always anxious to learn, and have gone to some expense to add to obtained knowledge in this important part of a gardener's duties. I should like to know what is meant by "Highest Circles." Does it include those who have fruit of their own, similar to what is seen at Chester, Shrewsbury, and other places on the fruit and decorative tables, or does it mean those who buy what fruit they want and employ decorators?

There is an advantage in having fruit handed round, an advantage I fear too many are ready to avail themselves of. I had looked upon the dessert tables at our best shows as a boon to gardeners who have much decorative work to do. "H. D." has "set me longing," and to use a frequent expression of our young men, I should like to see what others do. Horticultural societies have done much to help gardeners; could they still add another class? There are others, beside myself, who would like to see what is done in the "Highest Circles."—S. B. O.

[It is highly creditable to young men to give willing aid in outdoor work of the nature indicated. It is excellent practice, and they will

never regret doing their best outside their particular domain under glass. It is this combination of work in their youthful days that has made most of our leading gardeners what they are now, and no doubt "S. B. O." had his share of useful outdoor work in his probationary days.]

CHILLINGHAM CASTLE.

A FEW notes taken during the month of August at this fine old Border castle in Northumberland may interest the readers of the Journal. The name of Chillingham is generally associated with the famous wild cattle, which together with numerous herds of red and fallow deer, find a home in a spacious park nine miles in circumference. These animals still retain their wild nature, and are generally supposed to be survivors of the wild cattle that in days gone by roamed the Caledonian forests. The castle itself is very ancient, and is approached from the western, or main entrance, by a magnificent avenue of Limes a straight quarter of a mile in length.

The flower garden (fig. 60) is very extensive, and at the time of my visit was perhaps seen at its best. A border runs the entire length, and this was especially gay with hundreds of "Geraniums," Begonias, Calceolarias, and Lobelias, the whole backed by a fine old wall on which climbers and creepers of various kinds find a congenial home. Very noticeable were clusters of Crimson Rambler Rose, Tropæolum speciosum, Clematises, and others. Some fine masses of Hyacinthus candicans in two large beds had a striking effect springing from a groundwork of green Ferns. All edgings to walks are formed of Box, kept neatly clipped, which gives a finished appearance to the whole. The southern boundary is formed by a beautiful terrace, topped by the Yew hedges already mentioned in the Journal, where the Flame Tropæolum has made itself at home, these hedges being 100 yards long.

Broad sweeps of gravel and lawn, broken by a short avenue of magnificent Elms, complete the views on this side; so returning by way of the flower gardens, we pass through the pleasure grounds to the north of the mansion, where fine masses of Azaleas and Rhododendrons are noticed. In a few minutes we are within the kitchen garden walls which enclose six acres, devoted to fruit and vegetables. Conspicuous among many varieties of Apples were fine fruits of Lane's Prince Albert, Gravenstein, Cellini, Ecklinville, Emperor Alexander, Golden Noble, Mère de Ménage, Peasgood's Nonesuch (very fine), Northern Dumpling (a Codlin-shaped fruit), Hawthornden, Fearn's Pippin, and Yorkshire Beauty. Apricots on a south wall were carrying a good crop, but Pears and Cherries were under average. A large area outside the kitchen garden is devoted to Strawberries, John Ruskin and Noble being favoured early varieties, the former being some days in advance of the latter at Chillingham; and as a main crop Keen's Seedling is still relied upon, Elton Pine following on as a good late sort.

A look through the fruit houses revealed excellent crops of Grapes, Figs, and Peaches, whilst in numerous heated pits and frames Melons, Tomatoes, and Cucumbers are grown in great quantities, suitable for the requirements of a large establishment. In conclusion it is pleasing to add that Lord Tankerville, the noble owner, though fast verging on the nineties, still takes a great interest and pride in his gardens; the clean appearance and fine crops of which testify to the skill of Mr. Henderson, the esteemed head gardener, who was a worthy pupil of the late Mr. Wm. Thomson at Dalkeith.—T. H. BOLTON.

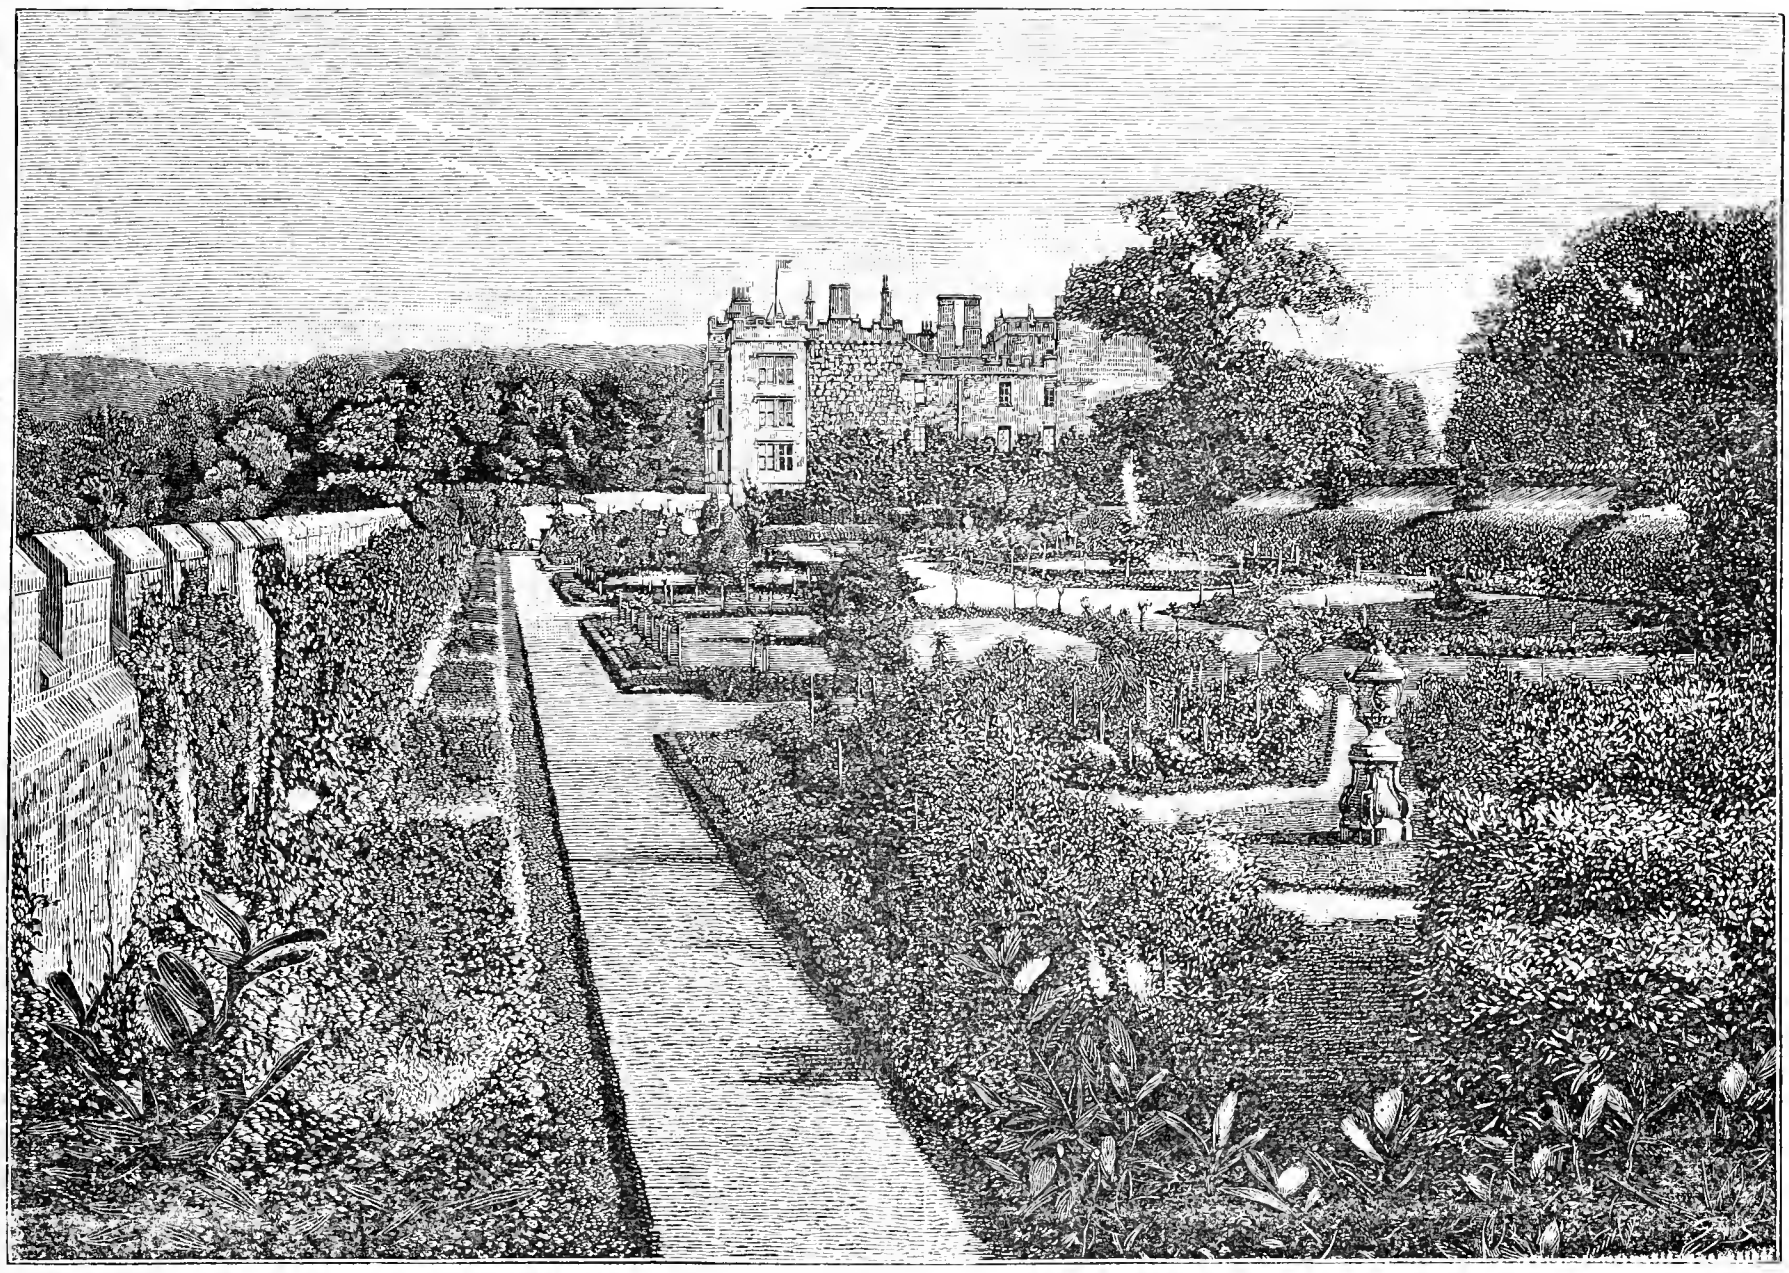

FIG. 60.—CHILLINGHAM CASTLE.

THE MANAGEMENT OF MEN.

WHEN a young gardener is called upon to take the responsibilities of his first head place he is confronted by many difficulties, to which he may not hitherto have attached due importance. Not the least of these is assuming the sole direction of other workers, and many a worthy young man has come to grief over this matter at the very commencement of the most critical portion of his career. All who have made any study of life know full well that there are some men who, from a lack of self-reliance or from some weakness of character, never seem to become qualified for the charge of others, though they may be admirable and skilled workers under proper direction. It is well when such men are aware of their own disposition, and have the good sense to make themselves contented if they are lucky enough to secure a good subordinate position. They can and do perform much useful service, which a wise superior will always duly value and recompense; they are usually free from the anxieties which often perplex a head gardener, and beyond that they commonly have a more secure office. The majority of young men who may have devoted ten or twelve years to a study of their calling are, however, sufficiently self-reliant to assume the cares of office, and to them the following remarks are addressed by one who was first placed in charge of men

over twenty years ago, and who has studied the art of management as an essential part of a gardener's duties.

It is of primary importance that the man in charge should not only understand every department of his calling, but be able to himself efficiently perform every operation connected with it. Without this thoroughness no head gardener can secure the respect and confidence of his men; and young men who in their learning days affect to despise those who apply themselves more industriously to the mastering of every detail may discover when it is too late that they have missed the road to success which their more assiduous fellow workers have found. Nothing places the authority of the master man upon a firmer basis than quietly proving to those under him that he is fully qualified for his position in the one respect at least which the men can judge—knowledge of the work.

It is needful also to make a study of men's varying dispositions, characteristics, and aptitude for particular work. Very much depends upon the overseer's skill in judging a man quickly in these respects; it gives him a natural power of direction which is soon appreciated, apart from the authority vested in his office. It facilitates the working of the whole establishment and increases the contentment of the men.

Whether a large or small establishment has to be dealt with, a code of rules is advisable, which, if only indicating the hours of work and for meals, with the conditions under which the men are engaged, more particularly in reference to the labourers, will assist in the maintenance of order. It seems unnecessary to speak of rules for a small establishment of three or four men, but there are always some understood and perhaps frequently disregarded, and it would be just as easy to have them in writing. Besides, order is as beneficial in a small body of men as in a large number, and it is something to teach men that it is to their own advantage, as well as to the employer's, to cultivate regularity.

Two points must be made essential; one is obedience to the chief, the other is punctuality. These should be as the laws of the Medes and Persians, and the wilful breaking of which must be punished by dismissal, if reprimand has failed to have any effect. No responsible man can carry on his charge satisfactorily if he cannot rely upon the implicit obedience of those under his direction, and for the same reason employers should never weaken their head men's authority by giving orders to subordinates. A true gentleman (or lady either) will recognise the evils resulting from such inconsiderate conduct, which are entirely contrary to their interests in every respect.

Whatever form the rules may take—and the more simple the better—they must be enforced, for nothing tends to a general laxity so much as overlooking the repeated infraction of a law. The enforcement must be done with judgment, however, and not arbitrarily, the object being to show that what is desired is regularity. In dealing with a very large body of men it will not be possible to exercise the same discretion in particular cases; general rules must be rigorously enforced or the "morale" of the whole place will be destroyed. If a new establishment is being started, or indeed, in any case, it is a wise precaution to submit the rules to the employer, as his sanction will strengthen the chief's hands greatly.

There are certain qualities which a gardener must possess and strengthen if he wish to rule satisfactorily, and two of these are firmness and an even temper. Everything must be well thought out before it is commenced, so that there may be no wavering or uncertainty afterwards. Let all orders and instructions be as definite and precise as possible, and if the enforcement of a rule becomes necessary there should be no hesitation, but decisive action must be taken. Then, too, if difficulties arise and a chief loses his temper habitually, he lessens his influence with the men, because he loses their respect, and because there is an innate recognition of the fact that to control others a man must first learn to control himself. I know men holding high and responsible horticultural posts, whose quiet manner might lead the unobservant to suppose they were extremely easy and even lax, but who, on the contrary, rule with exceptional firmness. It is an example of the kid glove covering a strong hand, the principle of the old Latin motto "*Sauviter in modo, fortiter in re*," freely translated as "Gentle in manner, firm in deed."

A superintendent of others must also be consistent in his decisions; a man who alters his opinion or behaviour frequently will not secure much attention. Another essential point is justice, which must be dealt out equally in the employer's interests and on behalf of the men. A really even-handed course of conduct is soon understood and appreciated, for there is a considerable amount of sound common sense in the great body of working men. They recognise that in exchanging their labour for the means of subsistence justice is due to them as much as to the employer. It is one of the head gardener's difficulties to balance the two interests, which should not be regarded as conflicting. Properly they are mutual interests, and it would be better for the work of the world if this truth were more generally recognised.

Lastly, the head gardener should be able to give both consideration and encouragement to his men where it is deserved. I have considerable faith in the majority of working men if they are treated well and ruled rightly, but there are exceptions, of course, who may be very troublesome. A really wrong-headed man, who will not recognise the obligations of life, should be disposed of at once; it is better for the master, and it may prove better for the man if there is any chance of a severe lesson effecting a reformation. For the obedient, industrious, and persevering, an occasional word of encouragement is a great help, particularly if it be followed when possible and prudent by more substantial recognition of worth.

These notes are not put forward as mere theorising about possibilities, but they indicate the course which experience with large bodies of men under difficulties of exceptional character has proved to be the most advantageous. It is not possible to smooth away all the difficulties of life, but these hints may be suggestive to young men and to them they are addressed.—SUPERINTENDENT.

CHRYSANTHEMUM SHOWS.

As is usual at this time of the year we have received numerous intimations of Chrysanthemum shows which are to be held during the coming season. Space, however, can only be found for mentioning those that have been advertised in our columns. If any have been omitted we shall be glad to add them to the following list. We append the names and addresses of the various Secretaries.

Oct. 29th and 30th.—BATTERSEA.—J. O. Langrish, 167, Elsley Road Lavender Hill, S.W.
Nov. 2nd and 3rd.—BRIGHTON.—J. Lewis, 37, Preston Road, Brighton.
„ 2nd and 3rd.—PLYMOUTH (West of England).—C. Wilson, 4, North Hill, Plymouth.
„ 2nd and 3rd.—CROYDON.—W. B. Beckett, 272, Portland Road, South Norwood.
„ 3rd and 4th.—WOKING.—H. W. Robertson, Chertsey Villa, Woking.
„ 3rd and 4th.—LOWESTOFT.—H. W. Bevan, 9, High Street, Lowestoft.
„ 3rd and 4th.—CARDIFF.—H. Gillett, 66, Woodville Road, Cardiff.
„ 3rd and 4th.—BLACKHEATH (Kent County).—F. Fox, The Cedars Gardens, Lee.
„ 5th and 6th.—ALTRINCHAM.—A. Hay, Navigation Road, Altrincham.
„ 9th and 10th.—LEEDS.—J. Campbell, Methley Park, Leeds.
„ 9th, 10th, and 11th.—ROYAL AQUARIUM (N.C.S.).—R. Dean, Ranelagh Road, Ealing.
„ 9th, 10th, and 11th.—BIRMINGHAM.—J. Hughes, 140, High Street, Harborne.
„ 10th and 11th.—HANLEY.—J. and A. Kent, Hanley Park.
„ 12th and 13th.—BRADFORD.—R. Eichel, 16, Westcliffe Road, Shipley.
„ 12th and 13th.—ECCLES.—H. Huber, Hazeldene, Winton, Patricroft.
„ 17th and 18th.—SOUTH SHIELDS.—B. Cowan, Harton, South Shields.
„ 17th and 18th.—HULL.—E. Harland and J. Dixon, Manor Street, Hull.
„ 17th and 18th.—BRISTOL.—E. G. Cooper, Mervyn Road, Bishopston, Bristol.

N.C.S. FLORAL COMMITTEE.

A MEETING of the Floral Committee of this Society was held at the Royal Aquarium on Monday afternoon last, the chair being taken by Mr. T. Bevan. There was a large quantity of blooms on view, and the quality was good. First-class certificates were awarded as under:—

Lady Hanham.—A sport from Viviand Morel. The colour is pale cream and salmon rose. Shown by Mr. W. Wells.

Mrs. S. C. Probin.—A very fine incurved Japanese. Broad florets and of good substance; colour flesh pink, reverse paler.

Pride of the Market.—A very free-flowering Japanese; colour golden yellow, suffused with reddish crimson. Exhibited by Mr. N. Davis.

Ella Curtis.—A Japanese, considered to be an improvement on the old Boule d'Or. Broad, curly, and intermingling florets; colour rich golden yellow inside, with reverse of pale yellow. From Mr. W. J. Godfrey.

Lady Ridgway.—An immense massive looking Japanese, with deeply grooved incurving florets of great breadth; colour reddish bronze, reverse light bronze. Also from Mr. Godfrey.

N.C.S. GENERAL COMMITTEE.

AT Anderton's Hotel, Fleet Street, on Monday evening last, there was a meeting of the General Committee of this Society, the Chairman

being Mr. T. W. Sanders. The minutes of the previous meeting were read and confirmed, and a good deal of correspondence and ordinary routine work disposed of.

The dates of the Society's shows for 1898 are proposed as follows :—September 6th, 7th, and 8th ; October 11th, 12th, and 13th ; November 8th, 9th, and 10th ; December 6th, 7th, and 8th. The Secretary then presented a rough financial statement concerning the cost and sale of the Society's Jubilee edition of the catalogue, which was, considering everything, regarded as satisfactory. The demand is steady, and it is expected that there will be a good demand for this work during the present season. Mr. Bevan called attention to the fact that at present there was no Catalogue Committee in existence, none having been elected early in the year, and he thought this was a matter that should be settled without delay.

It was announced that the Society's annual outing for 1898 had been fixed, and arrangements made with the G.E.R. Company to undertake entire charge of the party. This event is fixed for the 18th July. Stewards for the November Exhibition were elected, the following gentlemen being elected—viz., Messrs. Langdon, Simpson, Taylor, Willis, Ingamels, and Reeve. Following an old-established precedent, the Committee have invited members of the Floral Committee to dine together on the evening of the last day on which they meet—namely, 13th December, in consideration of their services to the Society.

Mr. Harman Payne called attention to a letter he had received from the President of the French National Chrysanthemum Society, M. Maxime de la Rocheterie, offering a cordial invitation to the members of the English Society at the Orleans Conference on the 6th November, and expressing a wish to see some blooms staged of English cultivation. No proposal, however, was made, there being apparently nobody desirous of making the journey, the French Show unfortunately clashing with the one at the Aquarium. It was announced that the annual dinner of the Society was fixed for Wednesday, the 24th November, at Anderton's Hotel, and that Mr. T. W. Sanders, the Chairman of the General Committee, would preside on that occasion. Thirty-one new members were elected, and the following Societies were admitted in affiliation :—The Wolverhampton Chrysanthemum Society and the Romford Society.

Honours for Chrysanthemum Raisers.

Some of our readers will be interested in learning that Mons. Ernest Calvat has recently been promoted from Chevalier to Officer of the Order of the Mérité Agricole, and that Mons. Alfred Chantrier, a raiser of more recent repute, has been appointed Chevalier of the same Order.

Chrysanthemum Leaf Rust.

It would be interesting to know if some varieties of Chrysanthemums are proof against the leaf rust. I grow some half-dozen varieties for producing medium-sized flowers for cutting, and amongst them every plant of Niveus is attacked rather badly, but I cannot find a leaf affected on any other variety. No incurved are grown.—Wm. Taylor.

Early Flowering Chrysanthemums.

Much excellent work has been done by the Royal Horticultural Society in its Gardens at Chiswick, and the careful trial of early flowering Chysanthemums that has been conducted, is another score to their record. In the experienced hands of Mr. S. T. Wright the trial has been admirably conducted, and the results most interesting as well as instructive. One long border, with two or three smaller beds, were requisitioned, and in the early part of this month there was a grand display. Some of the very early varieties were then almost over, while others were still only in bud ; but the majority were at the highest stage of their beauty. The Floral Committee of the Society visited the collection, and after careful inspection, awarded marks of honour in several instances. Many varieties had previously received recognition, and were not again given marks. A few varieties were of inferior merit and not worth growing.

Though we do not propose to particularise all those that secured awards of merit, we may advantageously make brief references to a few of the best in the collection. No effort was made to put them down in order of merit, but instead brief notes were made when in walking along a variety of special merit was seen. We may commence with L'Ami Conderchet, which in habit of growth strikingly resembles Aster acris. The numerous flowers are of a soft primrose shade. The dwarf free-flowering Madame Ed. Lefort, with its old gold coloured blooms, is certain to be admired, and the same remarks apply to Anastasia, of which the flowers are of a pinkish purple hue. A beautiful bronze is Fred Maronet, while Canari is a superb yellow. Both of these are dwarf and free. Another yellow of merit is Flora, which is exceedingly useful for cutting. White St. Croats and Mdlle. Jolivart are both pure white, though the first named has a conspicuous yellow centre. Longfellow, another white of pyramidal habit, is unsurpassed for cutting.

For dwarfness pride of place must be accorded to Dodo, which attains a height of only about 9 inches. As the plants are upwards of three-quarters of a yard through, and covered with bright yellow flowers, the effect they produce can easily be imagined. Madame M. Masse may be described as a deeply coloured Viviand Morel, and is of good quality. Mrs. Selby, rose pink in colour and very dwarf, must not be omitted, while Mytchett White must have a place in every collection. White Lady is also very fine. The lady's flower is Toreador, which is of a deep bronze colour. Piercy's Seedling and Golden Fleece are yellows of the highest quality, and with them this brief reference must close. The trial is a credit to the Society and to Mr. S. T. Wright.—D. R.

Early Flowering Chrysanthemums at the Aquarium.

Some decidedly good useful varieties of early flowering Chrysanthemums were exhibited at the recent Aquarium Show of the National Chrysanthemum Society. The varieties enumerated below were set up in bunches, these being sufficiently numerous not only to indicate the characteristics of each variety, but to show the effect produced by the liberal use of one variety. The varieties belonged largely to the smaller flowered section of the Japanese, and most of them will probably flower as well outdoors in a favourable position as under glass in pots

The description of colour may not in all cases be strictly as the flowers were seen under artificial light. Not any one variety can be said to be unworthy of employment in decoration, as the flowers were bright and fresh, producing an excellent display. They were also light and graceful, and formed a distinct contrast to the ever-increasing number of the imposing large-flowered varieties which bloom in October.

Albert Chausson is a rich orange, tipped yellow; Orange Child, a lemon yellow ; Notaire Croz, deep lilac or heliotrope ; Eclaireur, a good purple Japanese variety : Puisart Courboillier, crimson Japanese ; De la Guille, bronzy yellow ; Claret Belle, rich claret colour ; Ernest Mathieu, neat short-petalled flower ; Ambrose Thomas, crimson red, long narrow florets ; Montague, deep rich purple ; M. Backman, deep bronze ; Ivy Elphic, pink ; Mons. E. P. Van Geirt, yellow, striped red, erect pointed petals ; Queen of the Earlies, pearly white Japanese, broad florets, a lovely acquisition to early flowering decorative white Chrysanthemums ; Bronze Dwarf, colour, as its name implies, good ; Madame Eulalie Morel, lilac, florets yellow as opening ; President Lefevre, rose and white ; Sunshine, splendid rich bright yellow, a globular flower with broad petals ; Sam Barlow, narrow twisted florets, deep pink or lilac ; Rose Queen, rose lilac, incurving petals ; Roi des Précoces, deep crimson, a good and desirable variety, though not of recent introduction ; Mychett White, narrow florets, good ; Bronze Prince, bronze, yellow underneath petals.

Calvat's Introductions.

Among the recent introductions of the French raiser, Mons. Calvat, a very pretty and useful medium sized Chrysanthemum is Soleil d'Octobre. This is a canary yellow, rich and clear. The incurved variety Perle Dauphinoise is a good mid-October variety ; colour old gold. Madame Gustave Henry, with pure white long tubular florets, is in splendid condition about the same time ; so also is Mons. Hoste. This variety has very wide florets, being a Japanese reflexed. The colour is rosy white, tinted yellow. Vt. Roger de Chezelles, a lovely old gold and orange, is really a splendid flower with drooping florets.

Prominent New Varieties.

Mrs. G. W. Palmer is a sport from Mrs. C. H. Payne ; colour bronze, and the florets broad ; the flower is of large size. Geo. Seward is a fine orange bronze. Elthorne Beauty has full deep blooms, of a deep pink, the florets being very numerous, long and drooping. Simplicity is a remarkably fine white, forming a beautiful flower, with the petals incurving at the points. Emily Silsbury is another addition to white Japanese varieties. It has a creamy shade, but when rich and clear and the blooms fresh it is a chaste addition. John Neville is a massive bloom, crimson carmine colour, the reverse of the florets yellow. Red Warrior, a deep bronze. Mrs. H. Vachoul, purple, reverse of florets silver, and curiously twisted. Admiral Ito is a lemon yellow, full blooms of splendid size. A beautiful white with an unpronounceable name is Comtesse Jean de Lavochefoucauet.* Wm. Laycock is a lemon yellow with broad florets, twisted, incurving, and recurving. Mrs. Tucker Payne is a deep maroon with silver reverse.—E. D. S.

Chrysanthemums Damping.

For the edification or instruction of the younger members of the Chrysanthemum-loving fraternity, as well as to enlighten any who may be in a state of embarrassment caused by the, I may say, greatest evil a "Mum" grower has to contend with—viz., the damping of the blooms, I am prompted to contribute a few remarks to the columns of "our Journal" touching on this most important subject.

Damping arises from various causes. For instance, if the season be a wet one, or the weather be heavy or foggy, the evil is sure to be more or less felt ; again, if the houses in which the plants are placed are badly glazed it will put in an appearance, accompanied by mildew upon the foliage ; but to my mind overfeeding is at the bottom of the major portion of the trouble. Having been a grower for many years I have long held this conviction, and this year I am more than ever convinced that such is the case. Some six weeks ago it fell to my lot to take charge of a quantity of Chrysanthemums, which at first sight appeared to be all that one could desire, but when closely examined I quickly found that artificial stimulants had been applied too freely, the growths being exceedingly gross and thick, and lacking that rich colour and solidity of bark and wood which healthy and well-grown plants present. I at once saw that my only remedy to avert disaster from damping was to withhold stimulants altogether ; this I did, of course gradually, with the result that the majority of the plants that were then in bud have, as fast as the petals commenced to unfold themselves, been attacked, whilst others that were not so forward are expanding their blooms satisfactorily.

Taking the above facts into consideration, every thoughtful reader will at once come to the conclusion that the reason of the results achieved is not far to seek. The plants, having been gorged with stimulants, had, comparatively speaking, gone on all right ; but as soon as the growth

* Is it spelt correctly ? Perhaps if given its right name this might be more manageable.

ceased, and the formation of the bud took place, there was a temporary lull in the system of the plants, which, together with the condition of the roots caused by excess of various manures, brought on the disastrous results before stated. The reason of the later plants escaping the evil is, therefore, quite obvious, as the continuation of growth after withholding stimulants, having exhausted the manurial properties from the soil, the roots with the top growth were more in unison one with the other.

Respecting remedies for damping I do not think there is anything really effectual. Certainly, when caused by reason of heavy, foggy, or wet weather, and drip, it may be obviated to a certain extent by paying careful and strict attention to ventilating, by avoiding draughts or too sudden change of temperature, and by applying just sufficient fire heat to keep the air dry and sweet. But in cases of overfeeding, which, as before stated, I contend is in nine cases out of every ten at the very root of the mischief, I do not think there is any remedy.

In conclusion, I would say in reference to the use of artificial stimulants, let your motto be "Discretion with forethought."—G. PARRANT, *Wareham, Dorset.*

How Chrysanthemum Growers are Made.

THE Chrysanthemum shows up so brilliantly at this particular season that any gilding of "the golden flower" by a humble grower would be not only unnecessary but decidedly superfluous. As a gardener who ten years ago knew little more of the matter than the man in the moon, and having in that comparatively short period waxed and waned as a grower of exhibition blooms, I venture to express a few thoughts upon a matter in which so many are directly concerned. Moreover, to me at least, my present standpoint seems particularly favourable for a dispassionate view. The same influences, too, which forced me, an unwilling competitor, into the thick of Chrysanthemum contests, are sufficiently powerful and far-reaching to account for a great number, possibly the majority, of those who now pose as big bloom growers. Hence, in speaking for myself, I may perhaps be the mouthpiece of many similarly situated—gentlemen's gardeners.

As first impressions often go a long way, mine, derived from the first exhibition I witnessed, may commence this review. This exhibition was at Woolwich, and although some twenty-six years have elapsed since that genial old gardener, B——, my master, arranged to meet me and walk over in the evening after we had "cleaned up," one or two things recall it vividly to mind. Certainly the Chrysanthemums have but little to do with it, for so far as the show was concerned there was nothing to pay and, comparatively, but little to see. However, curiosity ran rather high, it being the first time anything of the kind had been heard of by me, and expectation, perhaps, went higher still on finding B—— at the trysting place in all the glory of a swallow-tailed coat and chimney-pot hat, this with a great deal of the chimney in it. Well, the show, which was styled a conversazione, consisting of more of the latter than the former, the buzz of which, assisted by a piano and a young lady who sang, helped the proceedings considerably.

Here and there a few "specialists"—these, I suppose, were born, not made—hovered around specimens, chiefly of the Rundle family, severely trained in the way they should go to cover balloon and umbrella trellises. What is now lacking in data upon the methods employed and results obtained by these pioneers of Chrysanthemum exhibiting must be compensated for in remarking that Woolwichians thought their show sufficiently important to invite the late Emperor Napoleon, then residing at Chislehurst, to pay it a visit. His Majesty responded, and had it all to himself, owing to the committee appointed to receive him presuming upon Imperial punctuality, finding when they were ready that the august visitor had been and seen and departed up to time.

Links all but invisible connect these first impressions with a show held a dozen years later, when the big blooms came very much as a surprise to me, although at this time a head gardener and grower of the usual complement to be found at that period in most private places. Peter the Great was a great thing then, Maiden's Blush and La Triomphante being also conspicuous among the Japs. Chrysanthemum society was at that time divided into two classes (and very strongly divided, too)—viz., those who grew big blooms, and those who did not. To the latter class, which was not slow in expressing pity, mingled with a little contempt, for the former misguided beings, I thought myself fortunate to belong, and possibly should still, had not circumstances beyond control rudely converted me. And how many gardeners are impelled by the same means! From this time very distinct was the advance in culture noted each year at our show, varieties annually waxing larger and brighter and better, and the more that this was the case the more did we outside the charmed circle condemn the whole system. I, in particular, had neither desire, nor room, nor time for such misapplied energy, but somehow each year found us at the show, where we ostensibly went to critisise, but covertly to condemn.

Speaking now for myself, and not for that great condemnatory party, which has apparently dwindled into comparative insignificance, I must openly confess that those big blooms, so fresh, so bright, so perfect, began to exert a talismanic influence, although the method of their production was still a mystery. But these big blooms eventually became the topic of higher circles—our masters and mistresses, principally the latter, who began to throw out hints, which clearly showed which way the wind was blowing. "Mrs. So-and-so would like you to go over and see her Chrysanthemums." "Mr. This will give you some cuttings of large kinds; and Lady That wonders you do not grow a few for the show." Soon hints became wishes, and an employer's wish is wisely interpreted as a command. Very reluctantly, and in a half-hearted way, I started on my exhibition career with 100 plants; went for the cup, and went nowhere near it, receiving a few more hints from head-quarters. Well, I did not say much, but thought a lot; in fact was fairly mettled—or nettled, perhaps being stung in sundry tender parts; so the succeeding year found me with Molyneux's little book and 300 plants, all for big blooms; but the cup, now so tantalising, went to another, whose conversion dated considerably further back.

There was less disappointment at this—the second venture—for my power over these plants now began to assert itself, and the following year with more plants, more knowledge, and the fever fairly raging, there was no slip 'twixt the cup and our stand of Japs, not to speak of a trophy for incurveds and sundry prizes in smaller classes. I can only say that it was with deep regret, from circumstances over which I had no control, that exhibiting had to be discontinued, and so far as my employers are concerned they like the small flowers for general decorative purposes, but insist upon having the big blooms as well for their own delectation and that of their friends. Hence we now grow those best suited for present purposes, without the high tension experienced in exhibiting, at the waxing of which, and the waning of which, I found, as doubtless hundreds have found, that "Discretion was the better part of valour."—EX-EXHIBITOR.

Chrysanthemum Prospects Round Bolton.

NOTWITHSTANDING the adverse atmospherical conditions, it is gratifying to note the many excellent collections grown in this neighbourhood. The season, in fact, promises to be the finest on record. Enthusiasm runs high amongst local growers, and with the show near at hand fine displays are anticipated, which arouses a healthy spirit of emulation. It is not my intention to enumerate what I found at each place separately. Suffice it to say that where they are grown for the exhibition board, or specimen plants, or for grouping, the outlook is most hopeful.

The most noteworthy amongst the Japanese are—Australian Gold, Arona, Mrs. Marling Grant, Mrs. Hume Long, Col. T. C. Bourne, C. W. Richardson, Modesto, L'Emindra, Indiana, Baron Ad. de Rothschild, Belle Mauve, Australie, Lady Byron, Lady Ridgway, Mons. Chenon de Leche, Mons. Demay Taillandier, Madame Ad. Chatin, Madame Carnot, Mrs. John Shrimpton, Mutual Friend, John Seward, Deuil de Jules Ferry, Emily Silsbury, Mrs. Briscoe Ironside, Mrs. W. H. Lees, Nyanza, and Amiral Avellan.

Amongst the incurved the most noticeable are Mrs. John Gardiner, L'Amethiste, Ma Perfection, John Fulford, Globe d'Or, Charles H. Curtis, J. Agate, Owen's Crimson, William Tunnington, Baron Hirsch, and Major Bonnaffon. The Queen and Princess family are especially good, and well timed for our coming show on November 19th and 20th, for which a very comprehensive schedule has been prepared, and liberal prizes are offered.

The leading class in the open section is twelve incurved and twelve Japanese blooms. The prizes for these are £5, £3, £2, and a 10-guinea challenge cup; other prizes in this section are especially good. The great event to the Bolton people is the President's (John Heywood, Esq., J.P.) prize, a silver cup, for twelve incurved and twelve Japanese blooms. This class is confined to growers residing within eight miles round Bolton.—R. S.

Glasgow Botanic Gardens.

FIFTEEN years ago I paid my first visit to the Glasgow Botanic Gardens, and have, with a few exceptions, made a rule to call at least once every year since. I again had the pleasure of looking through them on the 22nd inst., and also had the privilege of being shown the private departments personally by Mr. Dewar. I was so much struck by the healthy appearance of the Chrysanthemums that I thought a few remarks anent them would not be out of place, seeing we are about to enter another season of the autumn queen.

There are close on 4000 plants grown in 450 varieties. In the first place, I looked through two large span-roofed houses full of early varieties. I noticed several very good specimen blooms, and, the colours being nicely blended, they made a fine show. These, of course, were open to the general public, and in the private department there were several houses filled with the later varieties, and were well timed for the great exhibition to be held in the middle of next month. Each house, surveyed from a higher level than the plants, showed thousands of prominent buds, thrown well up above healthy, dark foliage, which cannot fail to make a handsome show. I also noticed that the grower thoroughly understands the art of feeding, as the surface of the pots was matted with healthy roots, which plainly denoted that there had been no gorging. Although they have passed through several thick fogs, I was told that there had been no damping.

Several of the earlier ones were in full flower, others were developing promising blooms, and amongst the best I noticed the following varieties:—Mutual Friend, Emily Silsbury (very good), Commandant Blusset, Madame Rouviere Houles, Edith Tabor, Simplicity, Lady Ridgway (pretty), Pride of Maidenhead (large), Mrs. W. H. Lees, Modesto, Amy Shea, Souvenir de Grenoble, Madame Gustave Henry (extra good), Mr. A. Newell, Duchess of York, Mrs. J. Shrimpton, H. Woolman, Phœbus, Mrs. G. Gover, Eva Knowles, Miss Rita Schroeter, Mrs. Bilsland, Mrs. Dewar (a grand white), and an unnamed seedling. The three latter are of Mr. Dewar's own raising, of which more will be heard. New York, Yellow Madame Carnot, Amiral Avellan, and Australian Gold. The Corporation of Glasgow encourages these exhibitions both in the Botanic Gardens and at Camp Hill, and a large winter garden on the green is now being erected for public displays, which are usually accompanied with first-class music. The citizens show their approval in thousands.

They may well be proud of their parks and gardens, and it would be good if other towns would follow more closely in their footsteps in such a worthy cause. W. RUSHTON.

STONELEIGH ABBEY.

GARDENERS are not a class who care to take many holidays, they are too much interested in attending to their duties at home. Sometimes, however, it is desirable for them to pay a little round of visits to some brother of the craft. A few days ago I managed to get a little diversion of that kind, and among other places visited Stoneleigh Abbey, Kenilworth, Lord Leigh's beautiful Warwickshire home. In the gardens I found Mr. T. Martin, busy, but still with time enough to show me round. In a span-roofed vinery some grand Alicante Grapes were growing, size of bunch, colour, and finish being of the first order.

I found, too, some splendid Chrysanthemums. The plants had been grown strongly from start to finish, yet it seemed not too strongly, for blooms as well as plants were grand. The varieties were principally Japanese ones, but I noticed in the incurved section wonderfully massive blooms of Baron Hirsch, neat examples of D. B. Crane, and the popular favourite, C. Curtis, gave promise for something good a little later on. Among the Japanese Mrs. W. H. Lees, Deuil de Jules Ferry, Eva Knowles, Graphic, Mons. Ch. Molin, Pallanza, Pride of Madford, Violetta, Edith Tabor, John Shrimpton, Phœbus, Miss D. Shea, Souvenir de Petite Amie, and Ethel Addison were conspicuous by reason of their good blooms. Mr. Martin has not grown his flowers with the object of showing them, but they are a good lot, and I think some of them ought to be placed under the eye of the public.—WANDERER.

CHRYSANTHEMUMS AT CHELSEA.

MESSRS. J. VEITCH & SONS of the Royal Exotic Nursery, Chelsea, have just now on view an interesting and comprehensive collection of the popular flower. French novelties are well represented, being mingled with a proportionate selection of American and home-raised varieties. The best of Calvat's novelties at Chelsea are Louise, Reine d'Angleterre, Le Moucherotte, Australian Gold, Mons. Chenon de Leché, President Borel, Amiral Avellan, M. G. Montigny, Souvenir de Petite Amie, L'Emindra, Japanese, white, slightly tinted; M. Geo. Biron, President Armand, Boule d'Or, and Commandant Blusset.

Another continental novelty worthy of notice is Leocadie Gentils, a pale lemon yellow sport, we think, from L'Enfant des Deux Mondes, or White Louis Boehmer as it is more generally known. This sport is large in size, and being of a pure tone of yellow will be a welcome addition to the hairy section. Octoroon, a large crimson and gold Japanese, and Mrs. S. C. Probin, Japanese incurved, with grooved pointed florets, are two American seedlings of promise. In yellows Mrs. Oporto Tait, A. H. Fewkes, Marjorie Kinder, Modesto, Sunflower, H. L. Sunderbruch, and Gold Dust are striking and effective. Lady Hanham, a beautiful large-sized flower, a pale rose and salmon buff sport from Viviand Morel, needs a special commendation, and is destined to become a very valuable addition to the showboard. In whites we find Emily Silsbury, Lady Byron, Pride of Exmouth, C. B. Haywood, Mrs. C. Blick, and Simplicity.

Mrs. G. W. Palmer is a sport from Mrs. C. Harman Payne, in colour varying from golden bronze to a rosy bronze. The well-known American varieties, Eva Prass, W. Tricker, Col. W. B. Smith, still remain favourites and are well done. Incurved are not numerous, but we noticed Baron Hirsch in good form, Prince of Wales, and Golden Beverley Mrs. Herman Kloss, a new Japanese, very rich warm terra cotta and gold; John Neville, Mutual Friend, Pride of Madford, Mrs. F. Jameson, Queen of Buffs, Mrs. C. Orchard (yellow), and others, show the extensiveness of the Chelsea collection.—VISITOR.

CALVAT'S NOVELTIES AT SWANLEY.

IN Messrs. Cannell & Sons' collection at Swanley there is a large number of very finely developed blooms of Mr. Calvat's raising. Some of the well-known varieties, such as Madame Carnot, Australian Gold, Ma Perfection, Le Moucherotte, Madame Gustave Henry, and Mrs. J. Lewis, need no description; but there are others, introduced last year and this, that appear worthy of a few notes.

Most striking of all is Madame Ed. Roger, a Japanese incurved with grooved florets, and a compactly built flower; the colour is an undoubted pure sea green, which, of course, grows paler as the flower ages. As a novelty Madame Ed. Roger is certainly entitled to be considered such, for it is the only green Chrysanthemum we have seen that deserves the name. Baronne Ad. Rothschild is a fine white Japanese of last year's set. N.C.S. Jubilee is a promising looking flower. It is solid and compact, and belongs to the Japanese incurved section, having florets grooved and rather broad; the colour is most attractive, being of a pale silvery lavender pink. M. B. Verlot is of the same type, but has narrow grooved florets; colour rosy mauve, reverse silvery pink. Madame K. Grenier, very pure white, a Japanese with grooved florets, is one of last year's set; so, too, is Capt. L. Chauré, big and solid, and of a rich golden yellow bronze. M. G. Chabanne is pretty; it belongs to the medium sized Japanese incurves, and has curly tips; colour gold bronze.

Souvenir de Molines is quite new; a solid compactly built flower, colour crimson bronze tipped and reverse gold. Iserette is another belonging to the present year's set, and was well shown at the Aquarium Show. It has medium-sized florets, and the colour is a rich golden bronze with orange chestnut inside. Another novelty is M. Massange de Louvrex, a fine yellow Jap. Madame A. Roussea, also quite new, is of medium size, colour rosy mauve, reverse silvery; Beauté Grenobloise, large white; Secretaire Fierens, very long florets, colour golden yellow and crimson bronze; Directeur Liébert, purple rose; Princesse de Galles, big blooms, colour pale pink shaded purple; and Mdlle. Lawrence Zédé, large lilac purple, are all of this season's set and worthy of looking out for.

Soleil d'Octobre is a very pure shade of yellow and an October-flowering variety of fair average size; President Nonin, yellowish buff shaded straw yellow; and Topaze Orientale, Japanese incurved, very close and compact, colour straw yellow; Madame Ferlat, pure white; M. Ed. André, Congrès de Bourges, Madame X. Rey, Jouvin, Madame G. Bruant, are others from the same grower. One of the best new whites is Mdlle. Lucie Faure, a fine compact Japanese incurved that was shown in first-class form last year at the Paris Show.—P.

CHRYSANTHEMUMS IN THE NORTH.

THE Committees of the numerous shows now find much difficulty in dating their fixtures so as to avoid clashing. The Harrogate Show, for this reason, has been fixed on the exceptionally early date for the district of November 4th. When passing through this popular health resort three weeks ago we took the opportunity to ascertain how the Chrysanthemums were going to respond to the demand of being to time in so late a district and cool autumn climate for which Harrogate is noted. We were fortunate in meeting Mr. Townshend, gardener to Mr. Becker Faber, Belvedere, just inside the station, and received a cordial invitation to look through the Chrysanthemums. The greater proportion of a large collection have been grown for grouping purposes. We found all the standard varieties for this purpose on the crown buds far advanced towards showing, their first developed florets giving promise of opening freely. We expressed some surprise to find them so early, and had doubts of about their being too forward, but were informed that on account of the cool situation there was nothing to fear in that respect. Mr. Townshend considers the prospect of a good bloom at least equal to previous years; but as he relies on well tried older varieties it is needless to record names.

CROW NEST PARK, DEWSBURY.

This collection is one of the best in the North. It is made up of more than 1000 plants: 500 are grown in first-class exhibition form, including the best up to date varieties of incurved, Japanese, and Anemones. The remainder are the freest blooming Japanese, Pompons of every grade, and all the best single varieties. The large flowering varieties are effectively staged in the middle of the large show house, and the smaller ones at the sides. Mr. Daniels, the park superintendent, has had in the past a long and successful exhibiting career, and is now as enthusiastic a cultivator as when he was winning prizes and silver cups. Although Crow Nest stands both high and bleak, by the closest attention in the earlier stages, and a knowledge of the constitution of each variety, he times his buds to the best advantage with the most satisfactory results.

Last year, during the three weeks the Chrysanthemums were on view, over 10,000 persons passed through the house. This year an equally rich treat is in store for Dewsbury people and neighbourhood, whilst Chrysanthemum lovers further afield will not begrudge time or expense after paying them a visit. Most of the large flowering varieties have been carried on to the second crown, and are now developing finely coloured flowers freely.

Of the newer varieties the following are proving reliable and good—Incurved: Bonnie Dundee, C. H. Curtis, D. B. Crane, Duchess of Fife, Globe d'Or, Lord Rosebery, and Mrs. R. C. Kingston. Amongst the older sorts some fine examples of all the types in the Queen and Princess of Wales families will be in evidence. A host of newer Japanese are grown, and remarkably fine examples of the following varieties will be in evidence—Beauty of Teignmouth, Boule d'Or (Calvat's), Col. Richardson, Charles Blick, Duchess of Wellington, Edith Tabor, Modesto, Miss Elsie Teichman, Miss Rita Schroeter, M. Gruyer, M. Demay Taillandier, Mutual Friend, Princess Ena Oceana, Palanza, Phœbus, Simplicity, and Duke of York.

SAND HUTTON, YORK.

Mr. Folkard, the well-known grower at Sand Hutton, writes: -"I am pleased to be able to state that the outlook in this neighbourhood seems to be a bright one, with perhaps one exception—viz., the Queen family. So far as one can judge at present, and from previous experience, I do not think they will be shown up to average form, owing chiefly to too early bud formation. The varieties alluded to are quite useless for show purposes, if the buds appear a few days too early, particularly if the weather is fine and bright after, as it is at the present time.

"I am of the opinion that it is not so much a question of 'ripe' wood as it is the time of bud formation suitable to the variety. I remember once having the best blooms of Madame C. Audiguier I ever saw, and the plants that produced the blooms were housed a fortnight before the buds appeared, and the shoots were more like young Willows, and could almost be tied in a knot. On the other hand, I am quite aware there are many varieties that are of little use in buds formed after the third week in August. A large majority of our buds appeared at favourable dates, and if 'ripe' wood and exquisitely tinted foliage is any criterion of good blooms, there certainly should be no lack of the latter. I never remember seeing the leaves of Chrysanthemums so beautiful.

"The Princesses are very promising, as also are the Tecks; C. H. Curtis, Mrs. R. C. Kingston, Lord Rosebery, Mrs. Tunnington, Jeanne d'Arc (very fine), and many others. Amongst the newer incurved Duchess of Fife and Miss F. Fowler are coming on fast; although crown buds of the former did not appear till the first week in September, they

are now unfolding their florets. Of the newer Japanese the following are very promising—Modesto (fine), Phœbus, Australie (very tall), Beauty of Teignmouth, General Roberts, Pride of Swanley, Australian Gold (on second crown), Dorothy Seward (very promising), Simplicity, a fine white, but rather early; the same with Lady Byron. Mrs. H. Weeks is a failure; plants stopped early in April did not show a bud till the middle of this month. I have nine promising buds of G. J. Warren opening freely. This variety appears to have a much better constitution than Madame Carnot, of which it is a sport."—A Yorkshire Grower.

Notes & Gleanings

Events of the Week. During the next few weeks horticulturists throughout the country will be busy amongst the Chrysanthemums. Shows are fixed for almost every day, and on one or two favoured dates there are about a dozen. On Friday, Oct. 29th, there will be Battersea; on Tuesday, Nov. 2nd, there will be Croydon, Plymouth, and Brighton; while Wednesday, Nov. 3rd, has been chosen for Woking, Cardiff, Lowestoft, and Kent County.

—— Weather in London.—The mildness that characterised the opening days of last week has scarcely been maintained since our last note was written. Thursday and Friday were slightly cooler, a little rain falling on the latter day. Saturday, Sunday, and Monday, though foggy in the mornings, were fine later in the day, and rather cool in the evenings. Tuesday was dull and wet, but Wednesday morning was finer.

—— Watering Fruit Trees.—It would be advisable in the present dry state of the weather if those having charge of fruit trees outside would ascertain the condition of the soil about the roots of their trees, particularly those against walls. In lifting some Peach trees recently they were found to be much drier than I like to see them at this season. These trees had been copiously supplied with water, but a gravelly subsoil accounts for their dry state. If fruit trees were better attended to in the matter of water at this season, and also liquid manure in the case of old trees, it is, I think, quite possible we might hear less of what is at times termed over-ripening or exhaustion after such a dry season as we have experienced.—W. S. G.

—— A Fruit Evening at York.—Under the auspices of the Ancient Society of York Florists both a pleasant and instructive meeting appears to have been held in the old city last Friday evening. The Rev. Gordon Salmon read an interesting paper on "Fruit Trees," and very fine fruit was sent by the following able cultivators:—Mr. G. Picker, Hesslewood, Hull; Mr. C. Lawton, Welton House, Brough; Mr. D. Williams, Duncombe Park; Mr. J. Allsopp, Dalton Hall, Hull; Mr. G. Harris, Alnwick Castle; Mr. Wrazzel, Bishopthorpe Palace; Mr. J. McIndoe, Hutton Hall, Guisborough; Mr. G. Taylor, Byram Hall, Pontefract; Mr. J. Hornby, Heslington Hall; Mr. Macintosh, North Riding Asylum; the Rev. Gordon Salmon, Overton Vicarage; Messrs. Backhouse & Sons, York; Mr. Everard, Holgate Lodge; and Messrs. G. Bunyard & Co., Maidstone.

—— Hessle Gardeners' Society.—A meeting of the above Society was held on Tuesday, October 19th, in the Parish School, Mr. Geo. Picker, Hesslewood, occupying the chair. The essayist for the evening was Mr. Garnett, St. John's Gardens, Wakefield, and the subject "Chrysanthemums." The Chairman, when introducing the essayist to the company, stated to what an extent Mr. Garnett was acquainted with Chrysanthemums, both in the capacity of grower and judge. The essayist took for his base the ripening process, and pointed out the complications caused by having over-ripe and under-ripe growths, also the difficulties the northern growers have to contend with to obtain the "happy" medium. At the close of the essay a discussion took place, and the number of questions asked showed that he had indeed fallen upon a hotbed of Chrysanthemum growers. The Chairman had some good blooms on the table, the varieties being Mrs. Hume Long, Phœbus, Boule d'Or, Emily Silsbury, Lady Byron, Baron Hirsch, and Mons. R. Bahuant. Mr. Blakey showed plants of Odontoglossum crispum and Cattleya labiata in flower. The meeting was the largest the Society has had, and this no doubt was caused by the subject and the essayist being so popular. The Secretary reported having received subscriptions from several gentlemen in the locality. A vote of thanks to the essayist terminated a very pleasant evening.—G. W. G.

—— Death of the Rev. C. S. P. Parish.—The death of this gentleman occurred recently at his residence, Roughmoor, Somerset, at the age of seventy-five years. The deceased was much interested in botany and Orchids. A Vanda, a Cypripedium, and other Orchids bear his name.

—— The Royal Gardens, Kew.—Messrs. Mackenzie and Moncur, Ltd., have been entrusted by H.M. Board of Works with the erection of a large temperate house in Kew Gardens. The house is to be constructed with iron girders, and teak sashes and sashbars. The carrying out of the contract will take about a year.

—— The Maidstone Nurseries.—Messrs. George Bunyard and Co. desire us to state that visitors can safely inspect their nurseries, as they are on high ground, two miles from the town, and in no way connected therewith by drainage or water supply. Upwards of a dozen medical officers certify that in their opinion the fever has been altogether due to the drinking of contaminated water, and that there is no possible danger to persons visiting the town. One of our representatives is looking forward with pleasure to a visit to the nurseries, near Barming Station, on the London, Chatham, and Dover Railway.

—— Railway Accidents or Negligence.—I had ten boxes of plants in pots down recently. Two of these boxes had been dropped, or something heavy put on them, and two-thirds of the pots and plants were smashed and rendered unsaleable. I made a claim on the Company, which they disallowed, on the ground that they were carried at owner's risk. Surely this does not permit of damage from carelessness?—St. Julien Arabin. [We always thought that railway companies were responsible for damage resulting from the negligence or carelessness of their officials. Possibly some of our readers may be able to give information on the subject.]

—— Birmingham Gardeners' Association.—The inaugural meeting of the autumn session took place on the 18th inst. at the Athletic Institute, Mr. W. B. Latham, the Botanical Gardens, Edgbaston, in the chair. Prizes in the shape of valuable and appropriate books were offered for collections of dried native wild flowers. The only contributor was Mr. C. Raffil, a student in the Botanical Gardens. The collection was a very good representative one, and comprised upwards of sixty species. Mr. C. R. Bick, gardener to Walter Chamberlain, Esq., contributed several freshly gathered wild flowers and autumn berries, including hipped sprays of various wild Roses. Mr. W. Gardiner (the Librarian) also brought a few species of wild flowers. On the 1st of November Mr. John Pope, King's Norton Nurseries, is appointed to give a lecture upon his tour in the Pyrenees last spring.

—— Literary Styles.—It may be, perhaps, that I am too old with the pen, for I have been a correspondent with gardening literature for thirty years, that I cannot get down to the level of "A Traveller's" intellect. Life is too short and work too serious to fit me to play the funny man. I daresay there are readers as well as writers who think that style clever and smart. I aspire not to be regarded as either, but to be solid, sensible, and I hope, too, honest. I have closely scanned the writings of the young men who have availed themselves of the "Young Gardeners' Domain," and have been pleased to see an entire absence of what is regarded as smartness. All honour to them. I trust they will stick to that suitable and excellent style. By doing so they will secure the respect and approval of their elders. When I cannot longer write matter that may be of practical service to horticulture I will lay aside my pen.—A. D.

—— Isle of Wight.—The first annual meeting of the East Cowes Horticultural Improvement Society was held last week, Capt. Harvey presiding. The Society has made satisfactory progress, having at present over one hundred members. Excellent papers have been read by Messrs. C. Martin, H. Cogger, J. Merritt, W. Tribbick, D. Sheath, A. Saunders, J. Jackman, J. Hygate, J. Barnes, and J. Broadwater on gardening subjects, whilst the County Horticultural Instructor (Mr. S. Heaton) gave a series of six lectures. Visits have been paid during the summer to the gardens of Messrs. J. S. White, J. Lee-White, and A. Hills, which proved interesting and instructive. A library has been established for the benefit of the members, and is receiving excellent support. After all expenses are paid there is a balance of £4 1s. 7d. in hand. In addition to a strong Committee, Messrs. A. Hills (Hon. Sec.), and C. Martin (Hon. Treasurer), have rendered great help towards the success of the Society. After a few sharp frosts, just sufficient to cut off the Dahlias in most places and give a littery appearance to gardens, we have a return of very mild and calm weather with sunshine, to make the very birds think by their song summer still remains. Ah! we are told "it is a weather breeder."—S. H.

—— Norfolk County Council.—Mr. G. Miller, market gardener, Wisbech, has been appointed to succeed the late Mr. Woodcock as lecturer on horticulture for the Norfolk County Council. We are informed that Mr. Miller has been a successful temperance lecturer in the county for several years.

—— Rudbeckia Golden Glow.—Allow me to correct an error I made about this through not being well up in nursery fancy names. I have since seen that "Golden Glow" refers to Rudbeckia laciniata flore-pleno, not to the plant I described, which has been called in nurseries "Autumn Glory," as I see by Barr's catalogue.—C. Wolley-Dod.

—— The Master of the Rolls.—The elevation of Lord Justice Lindley to the Mastership of the Rolls has been hailed with general satisfaction among the legal profession. It will interest horticulturists to know that Sir Nathaniel Lindley is one of the proprietors of "The Gardeners' Chronicle," of which well-known periodical his father was the first editor. The fame of Dr. John Lindley as a botanist and scientific lecturer on horticulture is still fresh in the recollection of the old generation, and from the distinction achieved by his son it is evident that the fine logical faculties exhibited by the father have lost nothing in transmission to the esteemed successor of the popular Lord Esher.

—— Extension of Business.—We are informed that the well known business of Mr. Andrew Potter, London Works, Reading, will henceforth be carried on under the name of "Potter, Hawthorn & Co." It has been found necessary, owing to the rapid increase in the business, to take in Mr. Hawthorn, who has been many years with Mr. Potter. It will be carried on under the personal supervision of them both, and they hope now to be able to give much quicker delivery than hitherto, especially when the additions to their already fine works have been completed. We may mention that their horticultural and poultry house branch has considerably exceeded their expectations, and they hope shortly to have the largest works of this kind in the South of England.

—— Death of Mr. W. A. Stiles.—It is with much regret that we have to record the death of Mr. W. A. Stiles, who has been the editor of the "Garden and Forest" since the inception of that publication some ten years ago. He passed away in Jersey City on the 6th inst. His personality was to be seen in the pages of the paper he edited week by week, and his own contributions on subjects in which he was interested were full of force, sound sense, and logic. In concluding an announcement of his death, our contemporary says:—"His death is a serious loss to the readers of 'Garden and Forest,' and to everyone in the United States interested in landscape gardening, horticulture, and the care and protection of our national and state forests. To this city (New York) at this particular time of his death is a great misfortune, for it leaves it without its most intelligent and powerful champion in the constantly recurring fight between the people and the would-be spoilers of their parks. Of his life-long devotion to those nearest to him by blood, untiring in its constancy and tenderness, we must not speak here; nor can we trust ourselves to speak of the faithful friend and associate tried by the test of long years of intimate relations, the wise counsellor and the joyous companion. Men who knew William A. Stiles loved him, and to them his memory will be immortal."

CHANGE OR DECAY.

Our "Traveller" trips lightly from page to page and man to man, giving each a gentle touch as he passes along. He seems to say in his tempting way, "Now can't you and won't you defend your own craft, and give me another text for dilation on the modern doctrine of mutual admiration?" His last journey must, I think, have been a pleasant, if not a profitable one; for he seems to be in wonderfully good humour with everybody, and especially with himself. True, he speaks of the "swell gardeners who hob-nob together at shows," but this not because of anything approaching a vindictive spirit, but simply born of a desire to compliment the masses. Still, it is rather a curious way to set about the task of proving that gardening is decaying; but then travellers, we all know, have ways of their own.

No trade or profession can be decaying when each year shows a wonderful increase in the number of those engaged in the work, and in the value of the produce it yields. One might as well argue that England is going to the dogs because its old aristocracy is yearly becoming poorer. It only shows that wealth is passing from the hands of one class to those of another. It is just the same with gardening. The fine old establishments are in many cases being broken up, but so many moderate sized and small ones are springing into existence, that the volume of good gardening is largely increasing.

We may not find good all-round gardening in so many places as formerly, but that is because their owners do not require many things that were formerly much prized, but in many cases prefer specialities to be made of certain things; and present-day gardeners—like the sensible men that they are—grow such things far better than they were grown a quarter of a century ago. Grapes, Peaches, Apples, Pears, grand plants in small pots, are now grown thoroughly well in a greater percentage of gardens than formerly.

When "Traveller" comes to what he terms "the decorations question" he asks quite a volley of questions, some of which have no bearing whatever upon the point at issue. My former position will be made quite clear, in fact unassailable, if I now state explicitly that, when I took charge of a garden, such as one that has been referred to, exactly the same number of hands were employed as in after years when there were no reductions whatever in the requirements in any direction, but a vast increase in the amount of decorative work required.

What a brilliant idea it was on the part of a "Traveller" to cull two lines from different parts of my former article, and then leave me to reconcile the apparently irreconcilable. I can do it quite easily, my travelling critic. Gardening is not decaying, but only changing in form. There may be evidence of deterioration in some places and in some phases of the grand old art, but the improvements and expansions in other directions overbalance the decadence a hundredfold.—Chrysanthemum Lover.

As the discussion on the alleged decadence in gardening has been very interesting, good humouredly personal, and in some ways useful; and as it has greatly enlivened your pages, and also been the means of bringing out some very practical cultural notes from correspondents who may be said to be new to us, I do not think you will begrudge the space taken up. The discussion has travelled over a good deal of ground, from "the decadence of gardening" and its suggested causes, "excessive floral decoration in flower garden and mansion," "commercial gardening," to "wall-fruit tree neglect, and consequent mismanagement, or no management," to "mutual admiration cliques," to "Mum worship and worshippers," to "youthful styles of writing,' and a few other items, but all and chiefly settling down to the charge of "A Traveller," that there is a general decay of gardening.

To that, as one nearing fast the threescore years and ten, with fifty years of practical gardening to quote from, with its fifty years of close observation and study of gardening in all its phases, with its fair acquaintance with the literature of gardening, and some personal knowledge of the men who have made their mark in the profession, and one who has taken a deep interest in the doings of young gardeners, and watched them very closely all that time, I say emphatically, "No; gardening in its widest aspect is not decaying!" That gardening is altering in its procedure and manifestations, I at once say, Yes, it is; but then it is but in that following out the great law of Nature—change, and is another confirmation of the inflexible law of evolution; one stage of the profession's life succeeding the other, and each stage differing from the last.

On change duration is founded; and though we who are getting older and slower and more conservative, if not prejudiced, in our ideas, do not take kindly to these new and advancing thoughts and ways, and lament with Sir Bedivere in "The Passing of Arthur," that—

> "The days darken round me, and the years,
> Among new men, strange faces, other minds,"

yet the wisdom, looking on both sides, which comes with years teaches us that these things are inevitable, and that it is our duty to make up our minds to them, and give cheerful and kindly welcome to those who are to take our places before long. Certain it is that if the new generation of gardeners has many in it like "H. D." (behind which initials we most of us know is one of the best and cleverest practical gardeners of the present day), we may be quite sure that gardening will never decay.

One word more, and I close this note. A correspondent who noticed my previous article seemed to think that I regretted the introduction of noblemen and gentlemen into the ranks of market gardeners. I assure him I do not. The inference I hoped would be drawn was, that the noblemen and gentlemen, with no rent to pay, and lightly assessed land, putting themselves into competition with the heavily rented and assessed professional market gardener, would very severely injure the humbler producer; that, though they might have been selling produce for some time, it was somewhat new that they should publicly proclaim themselves as fruiterers, dairymen, and market gardeners generally. I rejoice, and greatly rejoice, at any extension of the gardening profession in whatsoever way; more especially so in the extension of fruit growing which has gone on, and is going on, with leaps and bounds, thereby advancing our profession, and providing more food for the people. What we require in all our work in the present day is a greater respect for the opinions of each other, more thoughtful patience, and an increasing readiness to lay hold of every idea and practice which will bring out anything and everything to promote the betterment of gardening and gardeners.—An Old Provincial.

[While admitting the ability that has been displayed, both in friendly attack and defence, by the several correspondents who have taken part in the literary tournament on the subject in question, we are inclined to think, if a vote could be taken on the point, that the palm would be given to the oldest of them all—"An Old Provincial." His firm clear penmanship, with taste and accuracy in expression, are acquirements to be envied by many younger men, while his matured thought and expansive mind add weight to his observations. With this example of "nearly threescore years and ten,' a gardener in harness, who can dig as well as he can write, what ought not our modern braves to do? We shall shortly have a few words to say on the subject that has been so fully discussed, and in view of Chrysanthemum time, perhaps hoist the flag of truce.]

LOWDHAM AND CHILWELL.

UNFAMILIAR and familiar will be the above names to the majority of Journal readers, all of whom are acquainted with Chilwell. But Lowdham is new to the horticultural world, though ere many years have passed it will be known as a home of fruit trees and Roses. For upwards of a century the firm of J. R. Pearson & Sons has made its headquarters at Chilwell, and it has ever been renowned for the high quality of its stocks of plants and fruits as well as for the urbanity and probity of its owners. Last week both the new and the old establishments were visited with a view to getting notes for the *Journal of Horticulture*, and at each centre there was abundance of material to examine and about which to write. It is proposed, however, before dealing with each place separately, to give a brief paragraph of the two together, and then to turn first to the new and then to the older nurseries for more extended details.

Though fruit trees have been grown and sent broadcast over the country from Chilwell for many years, the output has developed within the last twenty years to an enormous extent. Some years ago the nurseries were stocked with all kinds of trees and shrubs, but these have been gradually crowded out, until the fruits practically reigned supreme. This meant that there was an area of 50 acres under fruit, and every yard of the ground was occupied. But with the growth of years ran concurrently the extension of trade, and of late it has been impossible to grow sufficiently large stocks of several of the most popular varieties of the various kinds of fruits. The heads of the firm realised that something would have to be done to overcome the difficulty. At the time this decision was arrived at the landlord quietly informed them that he was raising the rent 20 per cent. This did not exactly meet with approval, and to overcome that landlord the new ground was purchased at Lowdham.

It has been said that the Chilwell area comprised 50 acres. Remembering, then, that the extent of this was far too limited, the purchase at Lowdham of just double that number strikes one as showing a combination of judgment and enterprise. Further than this there is abundance of land adjoining that can either be rented or purchased as necessity may arise, which is practically certain to come as the years roll on and the trade advances still more. Each planting season brings increased orders to our great fruit nurserymen, and there is no reason to suppose there will be any decrease in the future. There still remain many hundreds of thousands of old, worn-out trees that must be displaced, and the same fate awaits the thousands of worthless local varieties which are found in all quarters of the country. Growers are realising that trees of the two types quoted do not pay for the space they occupy—not even the rent of the ground they cumber; and are planting young healthy stock of the most approved varieties of all kinds of fruits.

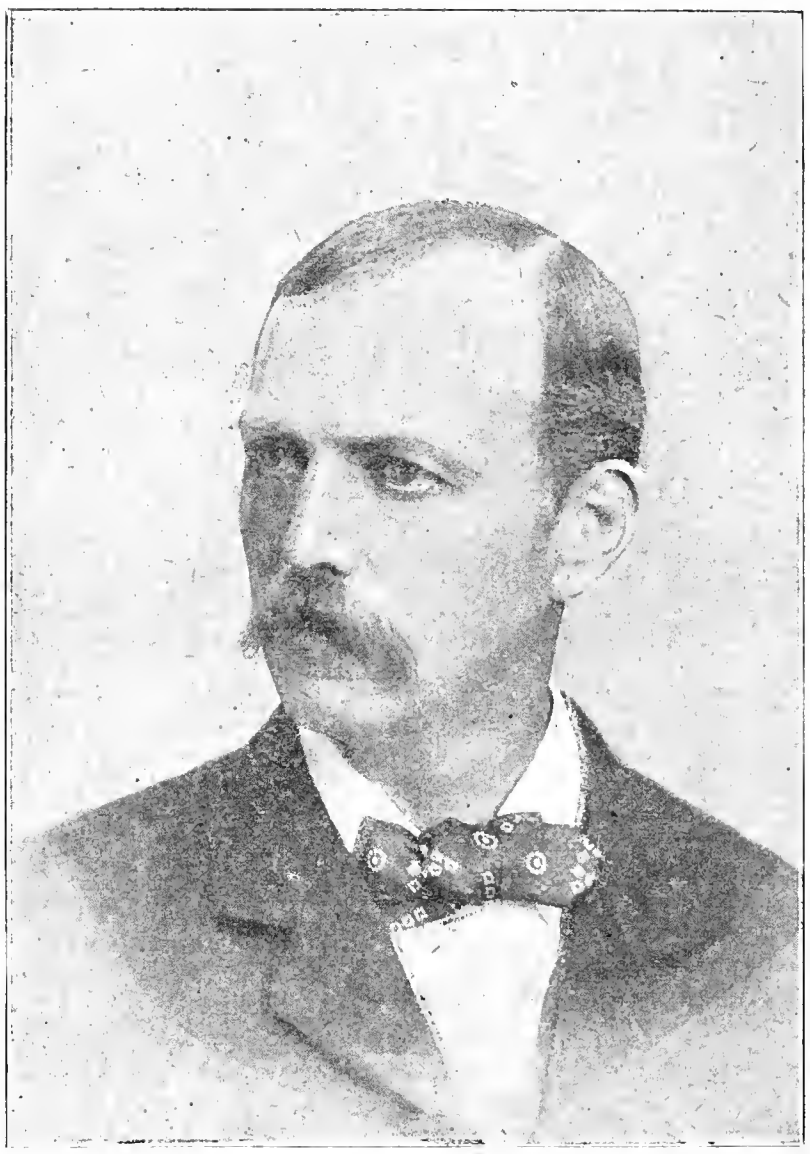

FIG. 61.—MR. ALFRED H. PEARSON.

LOWDHAM.

To speak now particularly of the new nursery we have to journey from Chilwell through Nottingham to a distance of six miles, or about twelve miles from the home establishment. It is quite in the country, and in this respect differs from the old nursery, which is in close proximity to two large towns besides Nottingham—namely, Beeston and Long Eaton. The Lowdham gardens are really in two portions, one of which is within three minutes of the station of the same name on the Midland Railway, and the other about ten minutes easy walking. Trains run with fair frequency, so that the place will have the distinct advantage of being easily accessible to those persons who may wish to personally select their trees. The small piece of ground referred to as being near the station has not yet been touched for planting, though it has been ascertained that there is a great depth of fine soil underlying the turf with which the surface has been covered for years. Here the offices and packing sheds will be erected.

On the more extensive area a considerable amount of work has been carried out, large portions of the ground having been cultivated, and several acres planted. The ground is undulating over the whole surface, distinctly hilly in places, and, needless to say, the soil varies widely, though it is all good. Almost the whole of the farm has been under pasture for scores of years. Perhaps the major portion of the staple is a sound holding loam, while there are besides large stretches of lighter loam, with several acres of an alluvial deposit. In only a narrow strip across a corner of one field is the soil less than 2 feet in depth, but in several instances 5 feet is found. It has been chosen by the expert, Mr. Alfred H. Pearson, in collaboration with Mr. Charles E. Pearson, who are the leading lights of the firm of J. R. Pearson & Sons. Of the first named, who is the fruit man, we have the pleasure of presenting, in fig 61, an admirable likeness, from a photograph by Messrs. A. Cox & Co., Nottingham.

In the selection of a proper site there was no haste, no jumping at conclusions. Miles of country were traversed, and every point in the surroundings of each place that might have any bearing on successful fruit culture was weighed to a nicety. The results must be gratifying indeed, for land has been secured, than which no better could be desired for fruit trees. It naturally requires cultivation, and anyone who is familiar with Mr. Pearson's methods knows that it will be given. The steam cultivator has been at work, and there has been no skimming of the surface, but a deep grip and a heavy turn-over. To insure the men doing good work, Mr. Pearson has spent many days riding up and down fields on the cultivator, only resting to partake of a *table d'hôte* lunch under a hedge or behind a smother. It is to be hoped that the *al fresco* life was enjoyed, and proved in all respects beneficial.

It is now just eighteen months since the work was initiated, and already many acres are under fruit and Roses, and the cultivation does not cease with the planting. In February of this year hoeing was commenced, greatly to the astonishment of the natives, who, in Mr. Pearson's own words, "thought I had gone mad," and we might add that it is a great pity other growers do not have similar attacks of madness, for there are method, sense, and reason in it. Then every acre has a little dressing of horse droppings applied as a mulch at the rate of between 50 and 60 tons to the acre. The effects of last autumn's mulching, and the early hoeing, are plainly seen, for, despite the dry weather, the plants grew and thrived, simply because the rains of the winter had carried food down to the roots, while the dusty surface soil had prevented waste of it by rapid evaporation. In places here and there a spade was pushed down into the soil and sunk easily to a depth of two blades.

We passed quarter after quarter stocked with trees, and everywhere there was the same uniform excellence. Some lifting had been done, and the trees had come up with large masses of fibrous roots almost on a level with the surface of the soil. By the way, immediately a tree is lifted the roots are securely covered with a mat so that they may not be exposed to the drying influences of the air, and they are kept covered until the packing stage is reached. Another excellent method of procedure that is worthy of universal adoption. The more the roots become shrivelled by exposure to the atmosphere the greater the prejudice against successful replanting. At Lowdham there are no aged trees, but there are maidens and espalier trees in thousands, as well as the various stocks that are utilised for working. All alike are in the best condition, and augur well for the success of the new nursery. Large quarters are to be planted this season, and if the present rate of stocking be maintained there will be very little unoccupied ground two years hence.

It is fortunate that there are several barns and outbuildings attached to the Lowdham homestead, but good cottages for the workmen were at a minimum. It has always been a practice of this firm to look well after its workpeople, and to this end four capital cottages are already erected, and more are in contemplation, so that the men will eventually be comfortably housed. That the employés appreciate these acts is proved by the length of time with which they stay with the firm, for there are now several who have served upwards of forty years, the record being held by one man with an unbroken service of sixty-four years. This veteran looked active, and ready for any amount of work. That the men like the treatment given to them is proved by an anecdote of the late Mr. J. R. Pearson and one of his men, who was employed for over seventy years in and about the nursery. Unfortunately he used to break out occasionally, and was promptly discharged. The following morning, however, always found him at work again, and remonstrance was wasted on him, for if his employer said anything the response would be to the effect that if Mr. Pearson did not know when he had a good man he knew when he had a good master, and he was not going to leave.

CHILWELL.

But let us return to see the fruit at Chilwell. The difference between the ground at the present moment and its condition some years ago when a visit was made was remarkable. Then the whole of the land was closely occupied, while now several acres are innocent of stock, owing to the removal in rapid progress. But that high standard of quality with which we were first impressed remains still. There is a beautiful cleanliness of wood and leaves, simply because preventive measures against pests are always taken. The energies of the trees must not be sapped by foes, either insect or fungoid. All forms of trees of all kinds of fruits are grown at Chilwell and Lowdham, but the best are the trained trees—Apples, Pears, and Plums as espaliers, with Peaches, Nectarines, Apricots, and Cherries in fan form—and the pyramids. Mr. Alfred Pearson commenced the culture of trained trees rather less than twenty years ago, and took the greatest pride in them. Every year they have in training his personal supervision—not given in any perfunctory

FIG. 62.—CHRYSANTHEMUM MADAME G. BRUANT.

manner either—with the result that, taken as a whole, a finer lot of examples of the best culture could not be wished for by anyone.

Last season 22,000 trees were trained in espalier and fan shapes, and this season this number has been exceeded. No better testimony than this can be needed as to the excellence of the trees when it is remembered that it is the result of less than twenty years' efforts. Pearson's trained trees are acknowledged as being in the front rank, and there they will stay. The pyramids, too, are models, while double grafted Pear standards are magnificent. Apples, Plums, Damsons, in fact all fruits, are there in various forms. Of some varieties, such as the grand Newton Wonder Apple, the numbers are nothing short of remarkable, but those that are known to be lacking in quality are not grown. As with the large fruits, so with the small. There are Gooseberries, Currants, and Raspberries in thousands, and again both in the form of bushes and trained, and all good. Weeds are not appreciated at Chilwell any more than they are at Lowdham, and very few were noticed in the tour round the whole of the quarters. Soon Chilwell as a fruit nursery will be almost a thing of the past, but Lowdham follows as the healthy offspring of a sturdy parent, and will, it is anticipated, more than maintain the best traditions of the firm.

Under Glass at Chilwell.

When one is at Chilwell and wishes to see any flowers other than outdoor Roses, one will have to leave Mr. A. H. Pearson for either Mr. Charles or Mr. Duncan Pearson. If Daffodils are the object of the visit, the latter will be the guide, for of these, with seeds and Dutch bulbs, he has made a speciality. For other things it is Mr. Charles who is the guiding star. No one would, of course, think of visiting at this time of year without looking at the Chrysanthemums, and these we examined until the necessity of striking matches to see a bloom warned us it was time to stop. But before this stage was reached we had seen many varieties, including the twice honoured Madame G. Bruant, which received the award of merit of the Royal Horticultural Society and the first-class certificate of the National Chrysanthemum Society on October 12th, when it was shown by Messrs. J. R. Pearson & Sons. It is, as may be seen by a reference to the engraving (fig. 62), a large Japanese, of which the centre colour is silvery white and the extremities of the florets soft rosy mauve. The other varieties we cannot now name, but the collection comprises every new and old variety worth growing. The plants are in splendid condition, and denote the excellence of the cultural methods to which they are submitted.

First amongst the other collections of plants grown must be noted the Zonal Pelargoniums, which are making a grand display. Then there are fine Grapes hanging over huge banks of Maidenhair Fern, a long span-roofed house of Maréchal Niel Roses, hundreds of pots of graceful Asparagus, vigorous old plants of Stephanotis, with scores of others, besides the Orchids. For these the Chilwell nurseries are not very widely celebrated, but there are many good ones there thoroughly well grown. The collection of Chatsworth Cœlogyne cristata is amongst the best in the country, while other kinds are little inferior. It was only a brief glance we could give to the houses, and the references must be very short; but we look forward to visiting Lowdham and Chilwell in the summer of some coming year, when the notes must be more commensurate with the excellence of the glass department.—Metropolitan.

GRAPES SHANKING.

Shanking may be looked upon as an indication that the Vines are not in perfect health, although their general appearance might lead to an opposite opinion. Several reasons have recently been put forward as the cause of this most injurious and perplexing malady. As it is brought about from various and opposite causes it is one of the most difficult to deal with.

There appears to be a consensus of opinion that the fault rests with the composition of the border and the absence of food material from it. There can be no doubt that the chemical composition of the rooting medium has an important influence upon Vines and their fruit; but, at the same time, I hold that the mechanical condition plays an equally important part in the health of Vines and their immunity from disease. In some instances it may be absolutely necessary to have a complete renewal of soil, but in many cases it is a waste of labour and material.

Shanking is caused by the Vines receiving a check at a critical period of their growth, and such check, in the majority of cases, is brought about either by an excess or a deficiency of water in the soil in which the roots of affected Vines are established. Doubtless the evil may be attributed to other causes, such as too much or too little food material, but without water Vines cannot obtain the requisite minerals, and an excess of it causes injury to the roots. I have frequently noticed that in low-lying districts, where there is some difficulty in providing efficient drainage, and also in naturally well-drained situations, where the soil is of a light or sandy description, that shanking is most prevalent.
